The antagonism of the opposition parties was even more pronounced. The tendencies which they represented had been present when the middle ages were yet at their height; but the papacy, while at the zenith of its power, had succeeded in crushing the attacks made upon the creed of the Church by its most dangerous foes, the dualistic Cathars (*q.v.*), Waldenses (*q.v.*) and kindred enthusiasts, who everywhere kept alive mistrust of the temporal power of the Church, of her priesthood and her hierarchy. In England the hierarchy was attacked by Wycliffe (d. 1384), its greatest opponent before Luther. Starting from Augustine's conception of the Church as the community of the elect, he protested against a church of wealth and power, a church that had become a political institution instead of a school of salvation; and against its head, the bishop of Rome. Wycliffe's ideas, conveyed to the continent, precipitated the outbreak of the Hussite storm in Bohemia (*see* HUSS; WYCLIFFE; LOLLARDS). This was open opposition; but there was besides another opposing force which, though it raised no noise of controversy, was far more widely severed from the views of the Church than either Wycliffe or Huss, namely the Renaissance, which began its reign in Italy during the 14th century. The Renaissance meant the emancipation of the secular world from the domination of the Church, and it contributed in no small measure to the rupture of the educated class with ecclesiastical tradition. Beauty of form alone was at first sought, and found in the antique; but, with the form, the spirit of the classical attitude towards life was revived. The men of the Renaissance wished to enjoy the earth by means of secular education and culture, and an impassable gulf yawned between their views of religion and morality and those of the Church. Theology could no longer provide a reconciliation. Since the time of Duns Scotus (d. 1308) theologians had been conscious of the discrepancy between Aristotelianism and ecclesiastical dogma. Faith in the infallibility of the scholastic system was thus shaken, and the system itself was destroyed by the revival of philosophic nominalism, which had been discredited in the 11th century by the realism of the great schoolmen. It now found a courageous supporter in William of Occam, and through him became widely accepted. But nominalism was powerless to inspire theology with new life; on the contrary, its intervention only increased the inextricable tangle of the hairsplitting questions with which theology busied itself.

In the meantime the Roman claim to the supreme government of the Church was steadily maintained. In 1512 Julius II. called together the 5th Lateran general council, which expressly recognized the subjection of the councils to the pope and also declared the constitution of Boniface VIII. (*see* above) valid in law. But the papacy that sought to win back its old position was no longer the same as of old. Eugenius IV.'s successor, Nicholas V. (1447–55), was the first of the Renaissance popes. Under his successors the views which prevailed at the secular courts of the Italian princes came likewise into play at the Curia: the papacy became an Italian princedom. Innocent VIII., Alexander VI., Julius II. were in many respects remarkable men, but they were scarcely affected by the convictions of the Christian faith. The terrible tragedy which was consummated on May 23, 1498, before the Palazzo Vecchio, in Florence, casts a lurid light upon the irreconcilable opposition in which the wearers of the papal dignity stood to mediaeval piety; for Savonarola was in every fibre a loyal son of the mediaeval Church.

Twenty years after Savonarola's death Luther made public his theses against indulgences. The Reformation which thus began brought the disintegrating process of the middle ages to an end, and at the same time divided Western Catholicism in two. Yet we may say that this was its salvation; for the struggle against Luther drove the papacy back to its ecclesiastical duties, and the council of Trent established mediaeval dogma as the doctrine of modern Catholicism in contradistinction to Protestantism.

C. THE MODERN CHURCH

The issue in 1564 of the canons of the council of Trent marks a very definite epoch in the history of the Christian Church. Up till that time, in spite of the schism of East and West and of innumerable heresies, the idea of the Church as Catholic, not only in its faith but in its organization, had been generally accepted. From this conception the Reformers had, at the outset, no intention of departing. Their object had been to purify the Church of mediaeval accretions, and to restore the primitive model in the light of the new learning; the idea of rival "churches," differing in their fundamental doctrines and in their principles of organization, existing side by side, was as abhorrent to them as to the most rigid partisan of Roman centralization. The actual divisions of Western Christendom are the outcome, less of the purely religious influences of the Reformation period than of the political forces with which they were associated and confused. Thus over a great part of Europe the Catholic Church was split up into territorial or national churches, which, whatever the theoretical ties which bound them together, were in fact separate organizations, tending ever more and more to become isolated and self-contained units with no formal intercommunion, and, as the rivalry of nationalities grew, with increasingly little even of intercommunication.

It was not, indeed, till the settlement of Westphalia in 1648, after the Thirty Years' War, that this territorial division of Christendom became stereotyped, but the process had been going on for 100 years previously; in some States, as in England and Scotland, it had long been completed; in others, as in S. Germany, Bohemia and Poland, it was defeated by the political and missionary efforts of the Jesuits and other agents of the counter-Reformation. In any case, it received a vast impetus from the action of the council of Trent. With the issue of the Tridentine canons, all hope even of compromise between the "new" and the "old" religions was definitely closed. Considered from the standpoint of the world outside, the Roman Church is, no less than the Protestant communities, merely one of the sects into which Western Christendom has been divided—the most important and widespread, it is true, but playing in the general life and thought of the world a part immeasurably less important than that filled by the Church before the Reformation, and one in no sense justifying her claim to be considered as the sole inheritor of the tradition of the pre-Reformation Church.

If this be true of the Roman Catholic Church, it is still more so of the other great communities and confessions which emerged from the controversies of the Reformation. Of these the Anglican Church held most closely to the tradition of Catholic organization; but she has never made any higher claim than to be one of "the three branches of the Catholic Church," a claim repudiated by Rome and never formally admitted by the Church of the East. The Protestant churches established on the continent, even where —as in the case of the Lutherans—they approximate more closely than the official Anglican Church to Roman doctrine and practice, make no such claim. The Bible is for them the real source of authority in doctrine; their organization is part and parcel of that of the State. They are, in fact, the State in its religious aspect, and as such are territorial or national, not Catholic. This tendency has been common in the East also, where with the growth

of racial rivalries the Orthodox Church has split into a series of national churches, holding the same faith but independent as to organization.

A yet further development, of comparatively recent growth, has been the formation of what are now commonly called in England the "free churches." These represent a theory of the Church practically unknown to the Reformers, and only reached through the necessity for discovering a logical basis for the communities of conscientious dissidents from the established churches. According to this the Catholic Church is not a visibly organized body, but the sum of all "faithful people" throughout the world, who group themselves in churches modelled according to their convictions or needs. For the organization of these churches no divine sanction is claimed, though all are theoretically modelled on the lines laid down in the Scriptures. It follows that, while in the traditional Church, with its claim to an unbroken descent from a divine original, the individual is subordinate to the Church, in the "free churches" the Church is in a certain sense secondary to the individual. The believer may pass from one community to another without imperilling his spiritual life, or establish a new church without necessarily incurring the reproach of schism. From this theory, powerful in Great Britain and her colonies, supreme in the United States of America, has resulted an enormous multiplication of sects.

Hence, from the period of the Reformation onward, no historical account of the Christian Church as a whole, and considered as a definite institution, is possible. The stream of continuity has been broken, and divides into innumerable channels. The only possible synthesis is that of the Christianity common to all; as institutions, they are divided, though they possess many features in common. The history of the various branches of the Christian Church since the Reformation will therefore be found under their titles: ROMAN CATHOLIC CHURCH; ENGLAND, THE CHURCH OF; PRESBYTERIAN; CONGREGATIONALISM; METHODISM; and others. The references given under the titles CHRISTIANITY, HERESY, and REUNION, CHURCH, may be mentioned here also.

The first real Church History was written by Eusebius of Caesarea in the early part of the 4th century. His work was continued in the 5th century by Philostorgius, Socrates, Sozomen and Theodoret, and later by Evagrius, Theophanes and others. In the West the history of Eusebius was translated into Latin by Rufinus and continued to the end of the 4th century. In the 6th century Cassiodorus had a translation made of the histories of Socrates, Sozomen and Theodoret, and brought down to 518. It was called *Historia Ecclesiastica Tripartita*, and during the middle ages was the principal textbook of Church History in the West. During the 5th, 6th and following centuries numerous works were produced containing more or less ecclesiastical material: biographies, chronicles, cloister annals and especially many local and territorial histories such as Gregory of Tours, *History of the Franks*, and Bede's *Ecclesiastical History of England*. The Protestant Reformation led to a new development of historical writing. In 1559 and following years a number of Protestant scholars published the *Magdeburg Centuries* to prove the primitive character of Protestantism, and were followed by Baronius (*Annales Ecclesiastici*, 1588 ff.) on the Roman Catholic side. Both works became the model for many others.

Church history began to be written in a genuinely scientific spirit in the 18th century under the leadership of Mosheim, whose most important work is his *Institutiones Historiae Ecclesiasticae* (1755), and was carried further through the new historical spirit of the 19th century in a series of works of which the most important are those of Gieseler, *Lehrbuch der Kirchengeschichte* (1826 ff. Eng. tr. by H. B. Smith), with copious citations from the sources, and still valuable; Neander, *Allgemeine Geschichte der Christlichen Religion und Kirche* (1825 ff., Eng. tr. by Torrey), with special stress on the religious side of the subject (*cf.* also Schaff, *History of the Christian Church*, 5th ed. 1889 ff.); Ferdinand Christian Baur of Tübingen (*Das Christenthum und die christliche Kirche*, 1853 ff.) whose many historical works were dominated by the principles of the Hegelian philosophy and exhibit both the merits and defects of that school; and Albrecht Ritschl (*Entstehung der alt katholischen Kirche*, 2nd ed. 1857), who broke away from the Tübingen school and built up new points of view. Among many more recent books may be mentioned that of W. Moeller, *Lehrbuch der Kirchengeschichte* (1889 ff., 2nd ed. by von Schuberth, 1898 ff., enlarged and improved), the translation of the latter being still the most useful textbook in English. Many references to historical works on specific branches of the subject will be found in the relative articles.

There are many editions of the works of the Fathers in the original, the most convenient, in spite of its defects, being that of J. P. Migne (*Patrologia Graeca*, 166 vols., Paris, 1857 ff.; *Patrologia Latina*, 221 vols., 1844 ff.). Of modern critical editions, besides those containing the works of one or another individual, the best are the Berlin edition of the early Greek Fathers (*Die griechischen christlichen Schriftsteller der ersten drei Jahrhunderte*, 1897 ff.), and the Vienna edition of the Latin Fathers (*Corpus scriptorum ecclesiasticorum Latinorum*, 1867 ff.), both of first-rate importance. There is a convenient English translation of most of the writings of the ante-Nicene Fathers by Roberts and Donaldson (*Ante-Nicene Christian Library*, 25 vols., Edinburgh, 1868 ff., American reprint, 9 vols., 1886 ff.). A continuation of it, containing selected works of the Nicene and post-Nicene period, was edited by Schaff and others under the title *A Select Library of Nicene and post-Nicene Fathers* (series 1 and 2; 28 vols., Buffalo and N.Y., 1886 ff.).

On early Christian literature, in addition to the works on Church history, see especially the monumental *Geschichte der altchristlichen Litteratur bis Eusebius*, by Harnack (1893 ff.). The brief *Geschichte der altchristlichen Litteratur in den ersten drei Jahrhunderten*, by G. Krüger (1895, English translation, 1897) is a very convenient summary. Bardenhewer's *Patrologie* (1894) and his *Geschichte der altkirchlichen Litteratur* (1902 ff.) should also be mentioned. Upon the spread of the Church during the early centuries see especially Harnack, *Mission und Ausbreitung des Christenthums in den ersten drei Jahrhunderten*, Eng. tr. *The Mission and Expansion of Christianity* (1907). An interesting parallel to the spread of Christianity in the Roman empire is afforded by the contemporary Mithraism; *see* Cumont's *Les Mystères de Mithra* (1900, Eng. tr., 1903). *See* also Hatch, *Influence of Greek Ideas and Usages upon the Christian Church*, 1890; Anrich, *Das antike Mysterienwesen in seinem Einfluss auf das Christentum*, 1894, Wobbermin, *Religionsgeschichtliche Studien zur Frage der Beeinflussung des Urchristentums durch das antike Mysterienwesen*, 1896; and for the organization of the early church, Harnack, *Mission und Ausbreitung des Christenthums*, pp. 337 *seq.*, and to the same writer's *Texte und Untersuchungen*, ii. 5 (Eng. tr. *Sources of the Apostolic Canons*, 1895); Fulbert Cayré, A.A.; *Precis de Patralogie*, French 1930, 1931; English 1936, 1940. (A. C. McG.; A. Hk.; W. A. P.; X.)

CHURCHILL, CHARLES (1731–1764), English poet and satirist, was born in Westminster, in Feb. 1731. His father, a clergyman, destined his son for the Church, and Charles was ordained in 1756. He was married at the age of 18, but his married life was unhappy and in 1761 he separated from his wife. He had lived a poverty-stricken life until that year, when he published, anonymously and without advertisement, the *Rosciad* at the price of a shilling. This brilliant but merciless satire described one by one the faults and eccentricities of the leading actors and actresses of the London stage, David Garrick almost alone escaping censure. It lay but a few days unnoticed in the bookshops; it was soon taken up with enthusiasm and the secret of its authorship publicly debated. It was attributed to Robert Lloyd, an amiable Welsh poet who, on Churchill's acknowledging the authorship, became his great friend. Churchill followed up the *Rosciad* with the *Apology*, in which his strictures were repeated and even Garrick was threatened. The actor sent through Lloyd an anxious and alarmed letter which flattered the poet by showing the fear which he already inspired. More, perhaps, even than his new-found power, Churchill enjoyed the wealth which his poems brought him. He paid his debts, made an allowance to his wife and started on a career of loose living and dandiacal dressing, which led, in 1763, after protests from his parishioners

and his bishop, to his being forced to resign his living. He defended in 1761 his method of life in a poem called *Night*, of which Smollett's *Critical Review* said in Dec. 1761, not unfairly, "This Night, like many others at this time of the year, is very cold, long, dark and dirty." With Sir Francis Dashwood and John Wilkes (*q.v.*) he drank wine in the globe at the top of West Wycombe church, and indulged in even less seemly pranks; he may even have been one of the famous Medmenham monks.

He became, in 1762, along with Lloyd, a close ally of Wilkes and assistant editor of the *North Briton* throughout its career, assisting its furious political campaign by rhymed satires which were almost equally feared: *The Prophecy of Famine* (1763), an attack on Lord Bute and the Scots, an *Epistle to William Hogarth* (1763), a reply to Hogarth's attack on Temple and Pitt; *The Duellist* (1763), an attack on Samuel Martin, M.P., who had attempted to kill Wilkes, and *The Candidate* (1764), an exposure of "Jemmy Twitcher," Lord Sandwich, Wilkes' chief enemy. His other completed works are *The Ghost, The Conference, The Author* (1763), *The Farewell, Independence, The Times* and *Gotham* (1764), of which the last is perhaps the best. He died of a fever on a visit to Wilkes in exile at Boulogne on Nov. 4, 1764.

Churchill was elephantine in figure: he has drawn his own picture in *Independence:*—

> Vast were his bones, his muscles twisted strong;
> His face was short, but broader than 'twas long;
> His features, though by nature they were large,
> Contentment had contrived to overcharge,
> And bury meaning, save that we might spy
> Sense lowering in the penthouse of his eye;
> His arms were two twin oaks; his legs so stout
> That they might bear a Mansion House about;
> Nor were they, look but at his body there,
> Designed by fate a much less weight to bear.

Churchill excelled in invective and malicious portraiture, as of Warburton, the pedantic and ambitious bishop of Gloucester:—

> Who was so proud, that should he meet
> The Twelve Apostles in the street,
> He'd turn his nose up at them all
> And shove his Saviour from the wall.
> (*The Duellist.*)

In his lifetime he was grossly overpraised and his death was lamented as a privation equal to the loss of Hogarth. Since then he has suffered an almost total eclipse. But he possesses great merits: his English is clear and vigorous, his wit and talent for invective are undoubted, and his poetic genius, of a Juvenalian character, much above the average. But it requires a great knowledge of 18th century politics and an equally great interest to appreciate his merits, and for that reason he is never again likely to be widely read.

See his *Collected Poems*, edited by W. Tooke with a biography and letters (1804), and re-edited by J. L. Hannay (1892), and the books cited under WILKES, JOHN. (R. W. P.)

CHURCHILL, LORD RANDOLPH HENRY SPENCER (1849–1895), English statesman, third son of John, 7th duke of Marlborough, by Frances, daughter of the third marquess of Londonderry, was born at Blenheim palace, on Feb. 13, 1849. He was educated at Eton and at Merton college, Oxford. In 1874 he was elected to parliament in the Conservative interest for Woodstock.

In 1878 he forced himself into public notice as the exponent of a species of independent Conservatism. He directed a series of furious attacks against some of the occupants of the front Ministerial bench. Sclater-Booth (afterwards 1st Lord Basing), president of the Local Government Board, was a special object of attack, and denounced as the "crowning dishonour to Tory principles." In the new parliament of 1880, Churchill began to play a more notable rôle. With the assistance of Sir Henry Drummond Wolff, Sir John Gorst and occasionally of Arthur Balfour, and one or two others, he constituted himself at once the audacious opponent of the Liberal Administration and the unsparing critic of the Conservative front bench. The "fourth party," as it was nicknamed, was effective in awakening the Opposition from the apathy which had fallen upon it after its defeat at the polls. Churchill roused the Conservatives and gave them a fighting issue, by putting himself at the head of the resistance to Charles Bradlaugh, the member for Northampton, who, though an avowed atheist or agnostic, was prepared to take the parliamentary oath. He continued to play a conspicuous part throughout the parliament of 1880–85, dealing his blows with almost equal vigour at Gladstone and at the Conservative front bench, some of whose members, and particularly Sir Richard Cross and W. H. Smith, he assailed with extreme virulence.

From the beginning of the Egyptian imbroglio Lord Randolph emphatically opposed almost every step taken by the Government. He declared that the suppression of Arabi Pasha's rebellion was an error, and the restoration of the khedive's authority a crime. He was equally severe on the domestic policy of the Administration, and was particularly bitter in his criticism of the Kilmainham Treaty and the *rapprochement* between the Gladstonians and the Parnellites. It is true that for some time before the fall of the Liberals in 1885 he had considerably modified his attitude towards the Irish question, and was himself cultivating friendly relations with the Home Rule members, and even obtained from them the assistance of the Irish vote in the English constituencies in the general election. By this time he had definitely formulated the policy of progressive Conservatism which was known as "Tory democracy." He declared that the Conservatives ought to adopt, rather than oppose, reforms of a popular character, and to challenge the claims of the Liberals to pose as the champions of the masses. His views were to a large extent accepted by the official Conservative leaders in the treatment of the Gladstonian Franchise bill of 1884. Lord Randolph insisted that the principle of the bill should be accepted by the Opposition, and that resistance should be focussed upon the refusal of the Government to combine with it a scheme of redistribution. The prominent, and on the whole judicious and successful, part he played in the debates on these questions, still further increased his influence with the rank and file of the Conservatives in the constituencies. At the same time he was actively spreading the gospel of democratic Toryism in a series of platform campaigns. In 1883 and 1884 he invaded the Radical stronghold of Birmingham itself, and in the latter year took part in a Conservative garden party at Aston Manor, at which his opponents paid him the compliment of raising a serious riot. He gave constant attention to the party organization, and was an active promoter and first member of the Primrose League, which owed its origin to the happy inspiration of one of his own "fourth party" colleagues.

In 1884 the struggle between stationary and progressive Toryism ended in favour of the latter. At the conference of the Central Union of Conservative Associations, Lord Randolph was nominated chairman, notwithstanding the strenuous opposition of the parliamentary leaders of the party. The split was averted by Lord Randolph's voluntary resignation; but the episode had confirmed his title to a leading place in the Tory ranks. It was further strengthened by the prominent part he played in the events immediately preceding the fall of the Liberal Government in 1885; and when Childers's budget resolutions were defeated by the Conservatives, aided by about half the Parnellites, Lord Randolph Churchill's admirers were justified in proclaiming him to have been the "organizer of victory." Owing to Lord Randolph's refusal to serve under Sir S. Northcote's leadership, Lord Salisbury had great difficulty in forming a cabinet in June 1885. Finally a way out of the *impasse* was found by elevating Northcote to the peerage (as earl of Iddesleigh) and giving the leadership in the House of Commons to Sir M. Hicks Beach. Lord Randolph was given the India Office, where "the India Council would be a check on him." (*Letters of Queen Victoria*, second series, vol. iii., p. 663.) During the few months of his tenure of this great post the young free-lance of Tory democracy attended to his departmental duties and mastered the complicated questions of Indian administration. In the autumn election of 1885 he contested Central Birmingham against Bright, and though defeated here, was at the same time returned by a very large ma-

jority for South Paddington. In the Home Rule controversy, both in and out of parliament, Lord Randolph again bore a conspicuous part. He was now the recognized Conservative champion in the lower chamber, and when the second Salisbury Administration was formed after the general election of 1886 he became chancellor of the exchequer and leader of the House of Commons. His management of the House was on the whole successful, and was marked by tact, discretion and temper. But he had never really reconciled himself with some of his colleagues, and there was a good deal of friction in his relations with them, which ended with his sudden resignation on Dec. 20, 1886. Various motives influenced him in taking this step; but the only ostensible cause was that put forward in his letter to Lord Salisbury, read in the House of Commons on Jan. 27, in which he stated that his resignation was due to his inability, as chancellor of the exchequer, to concur in the demands made on the Treasury by the ministers at the head of the naval and military establishments and that a better foreign policy might obviate the necessity for such demands. Although he himself refrained from offering any public explanation of his conduct, nor in any way sought to bring about a reconciliation with Salisbury, Lord Randolph Churchill's prestige was so great that a reconstruction of the cabinet proved a task of great difficulty. At length Goschen was induced to accept the chancellorship, and Churchill disappeared from any effective part in the leadership of the Conservative Party.

He continued, for some years longer, to give a general, though decidedly independent, support to the Unionist Administration. On the Irish question he was a very candid critic of Balfour's measures, and one of his later speeches, which recalled the acrimonious violence of his earlier period, was that which he delivered in 1890 on the report of the Parnell commission. He also fulfilled the promise made on his resignation by occasionally advocating the principles of economy and retrenchment in the debates on the naval and military estimates. In April 1889, on the death of Bright, he was asked to stand for the vacant seat in Birmingham, and the result was a rather angry controversy with Chamberlain, terminating in the so-called "Birmingham compact" for the division of representation of the Midland capital between Liberal Unionists and Conservatives. But his health was already precarious, and he bestowed much attention on society, travel and sport. He was an ardent supporter of the turf, and in 1889 he won the Oaks with a mare named the Abbesse de Jouarre. In 1891 he went to South Africa, in search both of health and relaxation. He travelled for some months through Cape Colony, the Transvaal and Rhodesia, and recorded his impressions in a book entitled *Men, Mines and Animals in South Africa.*

In the general election of 1892 he once more flung himself, with his old vigour, into the strife of parties. His seat at South Paddington was uncontested, and when parliament met he returned to the Opposition front bench to take a leading part in debate, attacking Gladstone's second Home Rule bill with especial energy. He died in London on Jan. 24, 1895.

Lord Randolph Churchill married, in Jan. 1874, Jennie, daughter of Leonard Jerome of New York, U.S.A., by whom he had two sons. In 1900 Lady Randolph Churchill married G. Cornwallis-West.

An authoritative biography of Lord Randolph, by his son Winston appeared in 1906; and a brief and intimate appreciation by Lord Rosebery, inspired by this biography, was published a few months later. Lord Randolph's earlier speeches were edited, with an introduction and notes, by Louis Jennings (2 vols., 1889). *See* also H. W. Lucy, *Diary of Two Parliaments* (1892); and Mrs. Cornwallis-West, *The Reminiscences of Lady Randolph Churchill, (i.e.,* of the author) (1908); *The Letters of Queen Victoria,* second series, 3 vols. (1926–28).

CHURCHILL, WINSTON (1871–1947), U.S. writer, was born in St. Louis, Mo., Nov. 10, 1871. He was graduated from the United States naval academy in 1894, soon devoting himself to writing. His first novel, *The Celebrity,* appeared in 1898. His next, *Richard Carvel* (1899), a novel of Maryland in the time of the Revolution, had a sale of nearly 1,000,000 copies. Then followed *The Crisis* (1901), the heroine of which is a descendant of his former hero, Richard Carvel; and *The Crossing* (1904). His other works include: *Coniston* (1906); *Mr. Crewe's Career* (1908); *A Modern Chronicle* (1910); *The Inside of the Cup* (1913); *The Dwelling Place of Light* (1917); *The Uncharted Way* (1941). Although his later work consisted chiefly of problem novels, his romantic tales of America's past were most popular. From 1903 to 1905 he was a member of the New Hampshire legislature, and in 1913 he was a candidate for the governorship as a Progressive.

He died Mar. 12, 1947, in Winter Park, Fla.

CHURCHILL, SIR WINSTON LEONARD SPENCER (1874–), British statesman, son of Lord Randolph Churchill and Jennie, daughter of Leonard Jerome, of New York city, was born on Nov. 30, 1874, at Blenheim palace, Oxfordshire. He was educated at Harrow and Sandhurst. Entering the army in 1895, he saw active war service with the Malakand field force (1897) and the Tirah expeditionary force (1898); attached to the 21st Lancers, he also served with the Nile expeditionary force and was present at the battle of Omdurman (1898). These campaigns gave him material for two brilliant books, *The Story of the Malakand Field Force* (1898) and *The River War* (1899). During the South African War (1899–1902) he was correspondent for the *Morning Post* and wrote an account of his experiences as *London to Ladysmith via Pretoria* (1900). He was taken prisoner by the Boers, but escaped.

Churchill was elected Conservative M.P. for Oldham in 1900 (having unsuccessfully contested the seat in 1899), and immediately made his mark in a house which expected great things from his father's son. He excelled in the set speech elaborately prepared on the classic models, but was not at first a ready speaker. Lord Balfour once said of him that he carried "heavy but not very mobile guns," and it was only later that he became a master in the cut and thrust of debate. He had a filial reverence for the political memory of his father and his *Life of Lord Randolph Churchill* (1906) is one of the most interesting political biographies in the language.

In 1904, when Joseph Chamberlain's tariff reform campaign seemed likely to turn the Conservatives into a party of protection, Churchill crossed the floor of the house and joined the Liberals. In the general election of 1906 he was returned for North-West Manchester and became undersecretary for the colonies in the Campbell-Bannerman government, 1905–08.

He soon won renown by his skill and authority in defending the policy of conciliation and self-government for South Africa. With his admission to the cabinet in 1908 as president of the board of trade his standing increased. His platform oratory had a vivacity, a boldness and an epigrammatic quality that stirred popular gatherings. Into the conflict that followed the rejection of the Lloyd George budget by the house of lords he threw himself with characteristic impetuosity. As home secretary (1909–11) he was responsible for carrying the Trade Boards act, directed against sweated industries, but was rather less successful in coping with the industrial disturbances of 1911.

Transferred to the admiralty later in the year, Churchill was explicitly enjoined by Herbert Asquith to put the navy into a state of "instant and constant readiness" in case of a German attack. He was not at first successful in creating the naval war staff which was generally thought desirable, but he did introduce many valuable reforms, both administrative and technical. When war came in 1914, it found the navy both efficient and prepared.

Churchill, who had been one of the most convinced supporters of the declaration of war on Germany, was the most strenuous advocate of aggressive land and sea campaigns. He carried out the Dardanelles enterprise of 1915 in face of the disapproval of the first sea lord, Sir John Fisher. Churchill left the admiralty for the duchy of Lancaster when the expedition proved a failure and Fisher resigned. When the Liberal government collapsed in the ensuing political crisis, Churchill abandoned politics for soldiering; he went on active service in France, where he commanded the 6th Royal Scots Fusiliers.

David Lloyd George, returning to power in 1917, recalled Churchill to office, first as minister of munitions and then as com-

bined war and air minister (1918–21). But apart from his conspicuous part in the Irish settlement, Churchill began to be less in agreement with the premier. Lloyd George disapproved of the costly British intervention in the U.S.S.R. that Churchill promoted. To be given the colonial office instead of the exchequer in 1921 was a severe disappointment. In the collapse of the coalition in 1922 Churchill lost even his seat in parliament, after representing Dundee since 1908.

Two years of retirement followed, filled, with characteristic versatility, by painting and writing. In 1924 he was returned to parliament from Epping as a Constitutionalist. Stanley Baldwin appointed him chancellor of the exchequer and in 1925 he rejoined the Conservative party. He presided over the return to the gold standard (1925), with the accompanying "revenue duties" and the derating scheme of 1928, measures not unproductive of controversy either then or since. In the same period he completed his work *The World Crisis* (1923–29).

With the fall of the Conservative government in 1929 a breach developed between Churchill and Baldwin. It began over India, where Churchill was opposed to any abdication of British imperial power—an opposition which led to his exclusion from the National government of 1931. In the nine years that followed Churchill led the life of a private member of parliament, writing the life of his great ancestor the 1st duke of Marlborough and only intervening in public debate on issues that profoundly moved him. As the Ramsay MacDonald, Baldwin and Neville Chamberlain governments pursued their policies of conciliation and surrender to the threats of Adolf Hitler, Churchill's protests became ever louder and more insistent. From 1936 to 1938 he particularly warned against German rearmament and British unpreparedness. In the commons' debate on the Munich agreement he asserted that it was "a defeat without a war" and "only the beginning of the reckoning." In March 1939 he pressed for an all-party government and in May urged an immediate agreement with the U.S.S.R.; to both proposals Chamberlain was cool.

However, on the British declaration of war on Sept. 3, 1939, Chamberlain in response to a wide popular demand appointed Churchill to his old post at the admiralty. His energy was soon felt not only within the department but also in the work of the cabinet. But the Norwegian defeats of April and May 1940 shook public confidence in Chamberlain's leadership, and on May 10, when the German armies entered the Low Countries, Chamberlain resigned to make way for the one leader, Churchill, who could form a national coalition government. Three days later Churchill made his celebrated speech to the commons in which he said, "I have nothing to offer but blood, toil, tears and sweat." Parliament gave him a unanimous vote of confidence.

This confidence was sustained throughout the four and one-half years that followed, stimulated by Churchill's rocklike trust in Allied victory and his frank, memorable and dynamic oratory. The story of his war premiership is the history of the British war effort because more nearly than any other war leader in British history he both directed and personified it, combining with the premiership the ministry of defense and taking a tirelessly energetic personal interest in every detail of administration. At moments of crisis he crystallized the national will, as in his memorable declaration on the occasion of Dunkirk, "We shall go on to the end, whatever the cost may be," or in the decision to reinforce the middle east in the dangerous autumn of 1940, or in the pledge to the U.S.S.R. on June 22, 1941, "Any man or state who marches with Hitler is our foe."

To nothing did Churchill more earnestly devote himself than to the construction and maintenance of what he called the "Grand Alliance." From the outset he looked forward to the day when, "The New World, with all its power and might," would step "forth to the rescue and the liberation of the Old." Churchill's conduct of relations with the United States and its wartime president, Franklin D. Roosevelt, was a remarkable blend of tact and candour, of a determination, as he said, not to "liquidate" the British empire and yet of a willingness to pool sovereignty and resources in a common cause.

With the U.S.S.R. he strove unceasingly to break down the barriers of misunderstanding—witness his dispatch to Moscow of Lord Beaverbrook in Sept. 1941, and of Anthony Eden in November and his own visit to Joseph Stalin in Aug. 1942. In Dec. 1941 he went to Washington, D.C., for the first of a series of conferences with Roosevelt. The year 1942 saw British reverses in Burma, Malaya and Hong Kong; but as U.S. strength gathered and the Russians fell back on Stalingrad, there was pressure on Churchill to agree to the early opening of a second front in Europe. Churchill thought this premature and successfully opposed it.

Even for 1944 he personally advocated an invasion of central Europe from the Mediterranean to coincide with the Normandy landings. However, Churchill's loyalty to an agreed strategy was as complete as his advocacy of his own views was powerful. Never in history had allied forces co-operated so harmoniously as in the strategy hammered out at the six planning conferences with Roosevelt and other leaders which Churchill attended in 1943.

The successes of 1944 brought new problems. At home and abroad Churchill was attacked for supporting allegedly reactionary regimes in Belgium, Italy and Greece. Meanwhile, his conversations in Moscow in October revealed the entering wedge of disagreements with the U.S.S.R. about eastern Europe.

The next year brought victory and great popular acclaim for Churchill. But the general election of June showed that this acclaim did not extend to Churchill, the Conservative party leader. Churchill bore the brunt of the election campaign himself, broadcasting and touring the country. But, although he retained his own seat, his party was severely defeated, and he began a long vigil as leader of the opposition.

During the first Labour government after World War II (1945–50) Churchill, still boundlessly energetic in his seventies, did not confine himself to parliamentary activities, master of debate though he still showed himself to be. He also embarked on a full-scale history of World War II (6 vol., 1948–53). His concern for British security and world peace did not flag. On March 5, 1946, in a speech at Fulton, Mo., he sharply criticized growing Soviet imperialism and advocated a "fraternal association" of the English-speaking peoples. On Sept. 19, 1946, at Zürich, Switz., he urged a closer unity in Europe, following it up with personal support for the Council of Europe, the first assembly of which he attended at Strasbourg, Fr., in 1949.

In the 1950 general election Churchill again led the Conservative party, and the Labour majority was reduced to seven. After his party won the election of Oct. 1951, Churchill again became prime minister. Here his single-minded devotion was to the cause of world peace, and his efforts were continuously bent on the realization of "talks at the summit" with Soviet leaders. However, age obliged his resignation on April 5, 1955, with these hopes unrealized although, by one of history's ironies, his chosen successor, Sir Anthony Eden, was able a few weeks later to announce to a British electorate Soviet and U.S. agreement to a four-power conference at Geneva, Switz.

Winston Churchill was named a knight of the Order of the Garter by Queen Elizabeth II on April 24, 1953. (H. G. N.)

CHURCHILL (Missinnippi or English), the name of a river of the province of Saskatchewan and province of Manitoba, Canada. It rises in La Loche (or Methy) lake, a small lake in 56° 30′ N. and 109° 30′ W., at an altitude of 1,577 ft. above the sea, and flows east-northeast to Hudson's bay, passing through a number of lake expansions. Its principal tributaries are the Beaver (305 mi. long), Sandy and Reindeer rivers. Between Frog and Methy portages (480 mi.) it formed part of the old *voyageur* route to the Peace, Athabasca and Mackenzie. It is still navigated by canoes, but has many rapids.

The Churchill is 1,000 mi. long. Churchill, at its mouth, is the best harbour in the southern portion of Hudson's bay. The river has enormous undeveloped water powers.

CHURCHING OF WOMEN, the Christian ceremony of thanksgiving on the part of mothers shortly after the birth of their children. Unlike the Mosaic ceremony (Lev. xii), it is not a rite of purification from uncleanness. In ancient times the ceremony was usual but not obligatory in England. In the Greek and Roman Catholic Churches today it is encouraged. No ancient

form of service exists, and that which figures in the English Prayer Book of today dates only from the middle ages. In the Prayer Book of 1549 the rite was called the Purification of Women; but this was altered in 1552 to the modern form, Thanksgiving of Women after Childbirth. (*See* Hooker, *Eccl. Pol.*, V, lxxiv.) Custom differs, but the usual date of churching was the 40th day after confinement, in accordance with the biblical date of the presentment of the Virgin Mary and the Child Jesus at the Temple. It was formerly regarded as unlucky for a woman to leave her house to go out at all after confinement till she went to be churched. It was not unusual for the churching service to be said in private houses. In some parishes there was a special pew known as the "churching seat." The words in the rubric requiring the woman to come "decently [*i.e.*, suitably] apparelled" refer probably to the custom of wearing a veil upon the head.

In the *Roman Ritual* (tit. vii. c. 3) the rite is called "The Blessing of a Woman after Childbirth." The mother is to kneel at the church door (more commonly at the altar rail), holding a lighted candle. The priest, vested in surplice and white stole (symbolizing gladness), sprinkles her with holy water and recites Psalm 23 (R.V. 24). Then, offering her the end of the stole that hangs to his left, he leads her into the church, saying in Latin: "Enter into the temple of God, adore the Son of Blessed Mary the Virgin, who has granted thee [the grace of] the birth of a child." The mother "kneels before the altar and prays, thanking God for the gifts given her"; and the priest utters a prayer for her temporal and eternal happiness and that of her child. Finally, he invokes upon her the abiding "peace and blessing" of the Trinity.

CHURCH OF THE BRETHREN: *see* GERMAN BAPTIST BRETHREN.

CHURCH OF THE NAZARENE: *see* NAZARENE, CHURCH OF THE.

CHURCH RATE, the name of a tax formerly levied in each parish in England and Ireland for the benefit of the parish church. Out of this rate were defrayed the expenses of carrying on divine service, repairing the fabric of the church and paying the salaries of the officials connected with it. The church rate was made by the churchwardens, together with the parishioners duly assembled after proper notice in the vestry or the church, and was a personal charge imposed on the occupier of land or of a house in the parish. Though it was compulsory, much difficulty was found in effectually applying the compulsion. This was especially so in the case of Nonconformists, who had conscientious objections to supporting the Established Church; and in Ireland, where the population was preponderatingly Roman Catholic, the grievance was specially felt and resented. The agitation against church rates led in 1868 to the passing of the Compulsory Church Rate Abolition act. By this act church rates were made no longer compulsory on the person rated but were made merely voluntary, and those not willing to pay them were excluded from inquiring into, objecting to or voting in respect of their expenditure.

CHURCH STRETTON, urban district, Shropshire, Eng., situated on a low watershed in a narrow longitudinal valley between the Longmynd and the Caradoc ranges. Pop. (1951) 2,580. Area 9.5 sq.mi. It takes its name ("Street Town") from the Roman road joining Viroconium and Caerleon, on which it lies. The Western Region railway from Shrewsbury to Ludlow and the main road parallel to it make use of this gap, where the railway reaches a height of 600 ft. As a market town Church Stretton serves the hilly country between Wenlock Edge and Longmynd, but the area is limited by hill barriers and much trade drifts to Shrewsbury on the north and Craven Arms and Ludlow on the south. The neighbourhood has numerous prehistoric camps and barrows, while a remarkable ridgeway or "portway" runs along the summit of the Longmynd.

CHURCHWARDEN, in England, the guardian or keeper of a church and representative of the body of the parish. The office dates from the 14th century, when the responsibility of providing for the repairs of the nave and of furnishing the utensils for divine service was imposed on the parishioners. Resident lay householders of a parish are those primarily eligible as churchwardens, but nonresident householders who are habitually occupiers are also eligible, while there are a few classes of persons who are either ineligible or exempted. The appointment of churchwardens is regulated by the 89th canon, which requires that the churchwardens shall be chosen by the joint consent of the ministers and parishioners, if it may be; but if they cannot agree upon such a choice, then the minister is to choose one and the parishioners another. If, however, there is any special custom of the place, the custom prevails, and the most common custom is for the minister to appoint one and the parishioners another. This was established by English statute, in the case of new parishes, by the Church Building and New Parishes acts, 1818–84. There are other special customs recognized in various localities; *e.g.*, in some of the larger parishes in the north of England a churchwarden is chosen for each township of the parish; in the old ecclesiastical parishes of London both churchwardens are chosen by the parishioners; in some cases they are appointed by the select vestry or by the lord of the manor, and in a few exceptional cases are chosen by the outgoing churchwardens. Each churchwarden after election subscribes before the ordinary a declaration that he will execute his office faithfully.

The duties of churchwardens comprise the provision of necessaries for divine service; the keeping of order during the divine service and the giving of offenders into custody; the assignment of seats to parishioners; and the presentment of offenses against ecclesiastical law. By the Parochial Church Councils (Powers) measure, 1921, no. 1, made under the Church of England Assembly (Powers) act, 1919, c. 76, all powers, duties and liabilities of the churchwardens relating to (1) the financial affairs of the church, (2) the maintenance and insurance of the fabric, goods and ornaments and (3) the maintenance of the churchyard (even when closed) were transferred to the parochial church councils. The property in the movable goods and ornaments remained in the churchwardens.

In the Protestant Episcopal Church in the United States, churchwardens discharge much the same duties as those performed by the English officials; their duties, however, are regulated by canons of the diocese, not by canons general. In the United States, too, the usual practice is for the parishes to elect both the churchwardens.

BIBLIOGRAPHY.—J. H. Blunt, *Book of Church Law*, 7th ed. (1894); C. G. Prideaux, *Churchwarden's Guide*, 16th ed. (1895); J. Steer, *Parish Law*, 6th ed. (1899).

CHURCHYARD, THOMAS (*c.* 1520–1604), English author, was born at Shrewsbury. He served in the household of Henry Howard, earl of Surrey, and in 1541 became a soldier of fortune. During the next 30 years he fought in almost every campaign in Ireland, Scotland and the Low Countries, now in the service of the emperor Charles V, now in the English service, at last under the prince of Orange. His last campaign was the defense of Zutphen in 1572.

Churchyard was employed to devise a pageant for the queen's reception at Bristol in 1574 and again at Norwich in 1578. He had published in 1575 *The firste parte of Churchyarde's Chippes*, the modest title which he gives to his works. No second part appeared, but there was a much enlarged edition in 1578. A passage in *Churchyarde's Choise* (1579) gave offense to Elizabeth I, and the author fled to Scotland, where he remained for three years. He was not restored to favour until about 1584, and in 1593 he received a small pension from the queen. The affectionate esteem with which he was regarded by the younger Elizabethan writers is expressed by Thomas Nashe, who says (*Foure Letters Confuted*) that Churchyard's aged muse might well be "grandmother to our grandiloquentest poets at this present."

His writings, with the exception of his contributions to the *Mirror for Magistrates*, are chiefly autobiographical in character or deal with the wars in which he had a share. They are very rare, and have never been completely reprinted. Churchyard lived right through Elizabeth's reign and was buried in St. Margaret's church, Westminster, on April 4, 1604.

BIBLIOGRAPHY.—The extant works of Churchyard, exclusive of commendatory and occasional verses, include: *A lamentable and pitifull Description of the wofull warres in Flanders* (1578); *A gen-*

eral rehearsall of warres, called Churchyarde's Choise (1579), really a completion of the *Chippes*, and containing, like it, a number of detached pieces; *A light Bondel of livelie Discourses, called Churchyarde's Charge* (1580); *The Worthines of Wales* (1587), a valuable antiquarian work in prose and verse, anticipating Michael Drayton; *Churchyard's Challenge* (1593); *A Musicall Consort of Heavenly harmonie . . . called Churchyard's Charitie* (1595); *A True Discourse Historicall, of the succeeding Governors in the Netherlands* (1602).

The chief authority for Churchyard's biography is his own "Tragicall Discourse of the unhappy man's life" (*Churchyarde's Chippes*). George Chalmers published (1817) a selection from his works relating to Scotland, for which he wrote a useful life. *See* also an edition of the *Chippes* (ed. J. P. Collier, 1870), of the *Worthines of Wales* (Spenser Soc., 1876) and a notice of Churchyard by H. W. Adnitt (*Transactions* of the Shropshire Archaeological and Nat. Hist. Soc., reprinted separately 1884).

CHURCHYARD, a piece of consecrated ground attached to a parochial church, and used as a burial place. It is distinguished from a cemetery (*q.v.*), which is also a place of burial, but is separate and apart from any parochial church. (*See* BURIAL.)

CHURL. In Old English law the word *ceorl* denoted the ordinary free man, who formed the basis of Anglo-Saxon society. In the course of time he lost much of his original independence, and after the Norman Conquest became included within the great class of villeins (*see* VILLEINAGE) who were regarded in law as personally unfree. It is largely owing to this depression that the word "churl" came to bear a derogatory sense. Nevertheless, even in Anglo-Norman law the *ceorl* had not wholly sunk into a servile position; he retained the wergild of a free man until the whole system of wergilds became obsolete, and he was long subject to the duty of attending public courts such as that of the Hundred (*q.v.*). His depression was due essentially to economic causes; men of his class suffered heavily in the wars of the 10th and 11th centuries and the lawyers of a later time who regarded their descendants as legally dependent upon their lords were only recognizing accomplished facts.

CHURN: *see* DAIRY MACHINERY AND EQUIPMENT.

CHURRIGUERESQUE, in architecture, the late, luxuriant, Spanish baroque style, so called from its most famous architect, Don José Churriguera (d. 1725). *See* RENAISSANCE ARCHITECTURE.

CHURUBUSCO, a village of Mexico on the river of the same name, about six miles south of the capital. It contains a massive stone convent. It was here that Major General Winfield Scott in his brilliant southern campaign of the war between Mexico and the United States (1846–48) fought the battle of that name as an aftermath of the action at Contreras the same day (August 20, 1847). Brigadier General Worth, who had been acting as rear guard at San Agustín, moved forward toward San Antonio to find, after trying a turning movement, that, on account of the victory at Contreras, the strong fortifications before him had been evacuated by General Santa Anna's Mexicans. Worth pressed on to meet stout and unexpected resistance at the bastioned bridgehead of Churubusco. Scott, taking charge of Pillow's and Twiggs' troops, a part of whom he sent to reinforce Worth, decided upon a turning movement. Sending Pierce and Shields over a road around Santa Anna's right flank, he ordered them to strike the Mexican general in rear. Though the untrained militia making the detour did not at first acquit themselves well, Worth stubbornly pressed in front and, after severe charging in which his troops succeeded in turning Santa Anna's left flank, was able to take the bridgehead and the well fortified convent beyond. The pursuit continued for over two miles. In addition to the guns and ammunition taken, the Mexican losses probably mounted to 10,000. The Americans lost about 950.

Ganoe, *The History of the United States Army* (1924); Original Correspondence and Reports in Old Files Section, Adjutant General's Office, Washington, D.C. (W. A. G.)

CHUSAN, an island archipelago off the Chinese coast. It represents the submerged terminus of the Tayu-ling, the dominating range of Chekiang, which is linked on south-westwards with the high ranges along the Fukien-Kiangsi border. The outermost islands of the archipelago lie across the entrance to Hangchow bay. Their shores are becoming choked with silt from the Yangtze estuary, which opens out just to the north of them, in perhaps the same way as at an earlier period the hills along the E. side of the Tai-hu became linked together by stretches of alluvium. If this interpretation is correct, the shallow Hangchow bay may in time become a second Tai-hu. By reason of its character as a rocky island and of its proximity to the Yangtze estuary, Chusan island, the largest of the archipelago, was during the Ming Dynasty (1368–1644) an entrepôt for trade with Japan. Until the modern development of Japan, Japanese relations with China were naturally most intimate in the neighbourhood of the Yangtze estuary. The Japanese use of Chusan at that time is somewhat comparable to the British use of Hongkong at a later period.

CHUTE, a channel or trough, artificial or natural, down which objects, such as timber, coal or grain may slide, identical in meaning and pronunciation with "shoot." A channel cut in a dam on a river for the passage of floating timber, and in Louisiana and on the Mississippi a channel at the side of a river or narrow way between an island and the shore. The "water-chute," a steep wooden slope terminating in a shallow lake down which run flat-bottomed boats, is a Canadian pastime, which has been popular in London and elsewhere.

CHUTNEY, a sweet pickle or relish prepared from sweet fruits such as mangoes, raisins, etc., with acid flavouring from tamarinds, lemons, limes and sour herbs, and with a hot seasoning of chillies, cayenne pepper and spices. The word is an anglicized form of the Hindustani *chatni*.

CHUVASH, an A.S.S.R. in the Russian Soviet Federated Socialist Republic, created as an autonomous area by decree in June 1920 and declared an autonomous soviet socialist republic in April 1925. Area 6,911 sq.mi. Its boundaries are: west, Gorki (formerly Nizhegorod); south, Ulianovsk; east, Tatar A.S.S.R.; north, Marii A.S.S.R. East of the Gorki province, from the junction of the Sura river with the Volga river, begins the forest area in which many Finno-Turkish tribes maintained their linguistic and racial individuality against the advancing waves of Slav colonization. Of these tribes the Chuvash occupy the area between the right bank of the Sura and Volga and are thus nearest to Moscow. The population (1939) 1,077,614 (urban, 131,533; rural, 946,081) includes Chuvash 80%, Great Russians 18%, Tatars and Marii (Cheremiss). The urban population is 85% Great Russians. In the south and west the republic is forested, but toward the north and east the forest remains only in patches. Deforestation became a serious problem, for much of the timber cut was not replaced. From ancient times lumbering, sawmilling and the making of wooden articles (*e.g.*, furniture, oak rivets, barrels, wagons, shovels) were the chief industries of the Chuvash. In modern times light manufacturing and machine production made industry equal in importance to agriculture. The chief industrial items exported are wood (mainly oak) articles and construction materials.

Agriculture was not well developed because of poor soil and climatic conditions and the primitive methods adopted. The soils are podsolized or degraded soils and liched black soils (*see* RUSSIA: *Soils and Their Influence*). The climate is severe; snow covers the ground from October to April, and the rivers are frozen. There are fierce storms in winter and spring, and in June and July thunderstorms are frequent. The prevailing winds are southwesterly, and in the hot summer they bring sand from the steppe, so that the crops are covered with dust. Oats and rye, once the main crops, were varied by the introduction of buckwheat, potatoes, fodder crops, hemp, flax and tobacco. Peas and lentils are also grown. The chief agricultural exports are oats, by waterway to Leningrad and by rail to Moscow, and eggs and poultry. Small quantities of honey, apples and hops are also exported. Though Chuvash horses, cattle, sheep and pigs are underfed and undersized, cattle, meat, wool and hides are exported. The standard of living is low and the imports are mainly salt, kerosene and iron goods, but in spite of the few cultural needs of the people there are many bazaar centres and several annual fairs.

Cheboksary, on the Volga river, the administrative centre, is a river port with an electric plant, a radio station and a Chuvash

regional museum, and its fair is the most important. It also has sawmills, printing works, dried fruit, starch and syrup industries, and it produces flour, alcohol and leather goods. The Yadrinsk oil-pressing factory was established at Cheboksary. Hemp, fulling and metal industries of a *koustar* (peasant) and semi-*koustar* type were set up, as were several steam flour mills. The Volga and Sura rivers provide navigable waterways in the summer. The Kazan to Kanash railway, linking through Arzamas in the Gorki province, is the shortest route to Moscow. Kanash (formerly Shikhran) is an important timber and grain centre. It is also the centre of the railroad system of Chuvash, one of the best developed in the U.S.S.R., with four lines radiating from it. One of the branches leads to Cheboksary and was built just before World War II. Another goes southwest through Alatyr, also a grain and timber centre, with an elevator. The Alatyr district is noted for its *koustar* furniture industry, and Alatyr is the largest city in the republic. It has locomotive and car factories, metalworking and sawmilling industries, and clothes and knitted goods are manufactured there. Located at smaller cities in Chuvash are a shipbuilding yard and a chemical plant which produces phosphate meal and other chemicals from the phosphorite and oil shale deposits which are fairly extensive in the area.

In order to combat illiteracy, which was still prevalent after World War I, the soviet government inaugurated a policy of instruction in the vernacular, which belongs to the Tatar or Turkish group but has many Finno-Ugrian idioms. A Chuvash daily paper was issued and in Cheboksary a theatre was established. The Chuvash are of Finno-Tatar origin, rounded-headed, flat-featured and light-eyed; they are thought by some to be the descendants of the ancient Bolgars. Their preferences tend toward agriculture rather than toward industrial occupations.

CHVALA, EMANUEL (1851–1924), Czechoslovak composer and critic, was born in Prague on Jan. 1, 1851. He studied both piano and theory of composition. In 1878 Josef Sladka suggested he attempt musical criticism, and it was in this field that he made his greatest contribution to Czechoslovak art. He wrote articles for Sladka's publication *Lumir*, and he also contributed to *Dalibor*, *Politik* and other journals. His essays in German, *A Quarter Century of Bohemian Music: 1862–87*, helped to introduce the music of his land to a wider audience. His compositions include songs and chamber and piano music. A concert overture; a *sinfonietta*, *Impressions of Spring;* and *Wake-Night*, a tone picture, were considered the most successful of his works. Simultaneously with his musical career, Chvala was director in chief of Czechoslovakia's state railways. He died in Prague on Oct. 28, 1924.

CHWANBEN: *see* SIKANG.

CIALDINI, ENRICO (1811–1892), Italian soldier, politician and diplomatist, was born in Castelvetro, Modena. In 1831 he took part in the insurrection at Modena, fleeing afterward to Paris, whence he proceeded to Spain to fight against the Carlists. Returning to Italy in 1848, he commanded a regiment at the battle of Novara. In 1859 he organized the alpine brigade, fought at Palestro at the head of the 4th division, and in the following year invaded the marches, won the battle of Castelfidardo, took Ancona and subsequently directed the siege of Gaeta. In 1861 his intervention envenomed the Cavour-Garibaldi dispute. Placed in command of the troops sent to oppose the Garibaldian expedition of 1862, he defeated Garibaldi at Aspromonte. Between 1862 and 1866 he held the position of lieutenant royal at Naples, and in 1864 was created senator. On the outbreak of the war of 1866 he resumed command of an army corps, but dissensions between him and La Marmora contributed to the defeat of Custozza. In 1867 he attempted unsuccessfully to form a cabinet sufficiently strong to prevent the threatened Garibaldian incursion into the papal states, and two years later failed in a similar attempt, through disagreement with Lanza concerning the army estimates. On Aug. 3, 1870, he pleaded in favour of Italian intervention in aid of France, a circumstance which enhanced his influence when in July 1876 he replaced Nigra as ambassador to the French republic. This position he held until 1882, when he resigned because of the publication by Mancini of a dispatch in which he had complained of arrogant treatment by Waddington. He died at Leghorn on Sept. 8, 1892.

BIBLIOGRAPHY.—G. Marcotti, *Il Generale Enrico Cialdini* (Florence, 1892); N. Nisco, *Il Generale Cialdini e i suoi tempi* (Naples, 1893); Prince Adam Wiszniewski, *Le Général Cialdini*, etc. (1913).

CIAMICIAN, GIACOMO LUIGI (1857–1922), Italian chemist, was born at Trieste on Aug. 22, 1857; his father was of Armenian origin. He was educated at Trieste and Vienna but took his doctorate at 1880 at the University of Giessen because he lacked the classic requirements demanded by all the other universities. He became assistant to Stanislao Cannizzaro (*q.v.*) and later reader in the Institute of General Chemistry of the University of Rome. In 1887 he was appointed professor of general chemistry in the University of Padua. In 1889 he accepted the chair of chemistry at the University of Bologna and retained this post until his death on Jan. 2, 1922. From 1910 to 1922 he was a member of the Italian senate, concerning himself mainly with education and the chemical industry.

Ciamician's most important researches were in organic chemistry. He stressed its application to biological chemistry rather than the discovery of new compounds. An investigation on the compounds in animal tar led him early in his career to the important researches on pyrrole. A monograph, *Il Pirralo e i suoi derivati* (1888), gained the royal prize of the Accademia dei Lincei. Ciamician was also a pioneer in the chemistry of vegetable products. At first he worked on organic compounds of vegetable origin and later became interested in the chemistry of the substances in the living plant and their biological significance. The essential oil of celery was the subject of an important early investigation; later he inoculated plants and seeds with alkaloids and with their constituents. His researches on the chemical action of light, many of them carried out in conjunction with Paul Silber of Rome, are noteworthy. The rear of the chemistry building was filled with shelves where hundreds of bottles and sealed tubes were exposed to the sun's rays. In addition there are a number of investigations by Ciamician in physical chemistry. Some of his earliest work was on the spectra of homologous elements; later researches were on theory of electrolytic dissociation, on solvates, on the nature of chemical affinity and on the valency of atoms. He published about 170 papers and delivered invited lectures before the German and French chemical societies and the International Congress of Applied Chemistry at New York city in 1912. A street in Trieste was named for him.

Nasini, *Journal of the Chemical Society*, Transactions 996 (London, 1926); R. Fabré, *Bull. soc. chim. France* [4] vol. 41, p. 1562 (1927); C. Harries, *Berichte d. deutschen chemischen Gesellschaft*, vol. 55 A, p. 19 (1922).

CIANO, GALEAZZO (1903–1944), Italian statesman, was the son of Count Costanzo Ciano (1876–1939), naval hero of World War I and a long-time legislative aide of Mussolini. The son entered diplomatic service in a South American embassy and was later consul general at Shanghai. In 1930 he married Mussolini's daughter Edda. In 1934 he became minister of propaganda, and during the conquest of Abyssinia he led a squadron of bombing planes. He was a member of the grand fascist council and in 1936 became minister of foreign affairs, a post he held until Jan. 1943, when Mussolini took over the ministry of foreign affairs himself, at the same time appointing Ciano ambassador to the Vatican. Ciano retained this position only six months, resigning in July 1943. On Jan. 11, 1944, Ciano and four other former members of the grand fascist council, all of whom had previously been convicted by a special fascist tribunal of high treason for plotting the overthrow of Mussolini, were executed in Verona.

CIBBER (or CIBERT), **CAIUS GABRIEL** (1630-1700), Danish sculptor, was born at Flensburg. He was the son of the king's cabinetmaker and was sent to Rome at the royal charge while yet a youth. He went to England during the Protectorate, or during the first years of the Restoration. Besides the famous statues of "Melancholy" and "Raving Madness" ("great Cibber's brazen brainless brothers"), now in the Guildhall, London, Cibber produced the bas-reliefs round the Monument on Fish street hill. The several kings of England and the Sir Thomas Gresham, exe-

cuted by him for the Royal Exchange, were destroyed with the building itself in 1838. Cibber was long employed by the fourth earl of Devonshire, and many fine specimens of his work are to be seen at Chatsworth. Under that nobleman he took up arms in 1688 for William of Orange, and was appointed, in return, carver to the king's closet. He died rich, and, according to Horace Walpole, built the Danish church in London, where he lies buried beside his second wife, to whom he erected a monument. She was a Miss Colley, of Glaiston, granddaughter of Sir Anthony Colley, and the mother of Colley Cibber.

CIBBER, COLLEY (1671–1757), English actor and dramatist, was born in London on Nov. 6, 1671, the eldest son of Caius Gabriel Cibber, the sculptor. Sent in 1682 to the free school at Grantham, Lincolnshire, the boy distinguished himself by an aptitude for writing verse. He was removed from school in 1687 on the chance of election to Winchester college. His father, however, had not then presented that institution with his statue of William of Wykeham, and the son was rejected, although through his mother he claimed to be of "founder's kin." The boy went to London, and indulged his passion for the theatre. He was on his way to Chatsworth, the seat of William Cavendish, earl (afterwards duke) of Devonshire, for whom his father was then executing commissions, when the news of the landing of William of Orange was received; father and son met at Nottingham, and Colley Cibber was taken into Devonshire's company of volunteers. Afterwards he enrolled himself (1690) as an actor in Betterton's company at Drury Lane. On his more than meagre earnings, which rose to £1 per week, supplemented by an allowance of £20 a year from his father, he contrived to live with his wife and family—he had married in 1693—and to produce a play, *Love's Last Shift, or the Fool in Fashion* (1696). Of this comedy Congreve said that it had "a great many things that were like wit in it"; and Vanbrugh honoured it by writing his *Relapse* as a sequel. Cibber played the part of Sir Novelty Fashion, and his performance as Lord Foppington, the same character renamed, in Vanbrugh's piece established his reputation as an actor. In 1698 he was assailed with other dramatists, by Jeremy Collier in the *Short View*. In Nov., 1702, he produced, at Drury Lane, *She Wou'd and She Wou'd Not; or the Kind Impostor*, one of his best comedies; and in 1704, for himself and Mrs. Oldfield, *The Careless Husband*, which Horace Walpole classed, with Cibber's *Apology*, as "worthy of immortality." In 1706 Cibber left Drury Lane for the Haymarket, but when the two companies united two years later he rejoined his old theatre through the influence of his friend Colonel Brett, a shareholder. Brett made over his share to Wilks, Estcourt and Cibber. Complaints against the management of Christopher Rich led, in 1709, to the closing of the theatre by order of the crown, and William Collier obtained the patent. After a series of intrigues Collier was bought out by Wilks, Doggett and Cibber, under whose management Drury Lane became more prosperous than it ever had been. In 1715 a new patent was granted to Sir Richard Steele, and Barton Booth was also added to the management. In 1717 Cibber produced the *Nonjuror*, an adaptation from Molière's *Tartuffe;* the play, for which Nicholas Rowe wrote an abusive prologue, ran eighteen nights, and the author received from George I., to whom it was dedicated, a present of two hundred guineas. Tartuffe became an English Catholic priest who incited rebellion, and there is little doubt that the Whig principles expressed in the *Nonjuror* led to Cibber's appointment as poet laureate (1730). It also provoked the animosity of the Jacobite and Catholic factions, and was possibly one of the causes of Pope's hostility to Cibber. Numerous "keys" to the *Nonjuror* appeared in 1718. In 1726 Cibber pleaded the cause of the patentees against the estate of Sir Richard Steele before Sir Joseph Jekyll, master of the rolls, and won his case. In 1730 Mrs. Oldfield died, and her loss was followed in 1732 by that of Wilks; Cibber now sold his share in the theatre, appearing rarely on the stage thereafter. In 1740 he published *An Apology for the Life of Colley Cibber, Comedian . . . with an Historical View of the Stage during his Own Time*, which gives the best account there is of Cibber's contemporaries on the London stage.

In 1742 Cibber was substituted for Theobald as the hero of Pope's *Dunciad*. Cibber had introduced some gag into the *Rehearsal*, in which he played the part of Bayes, referring to the ill-starred farce of *Three Hours after Marriage* (1717). This play was nominally by Gay, but Pope and Arbuthnot were known to have had a hand in it. Cibber refused to discontinue the offensive passage, and Pope revenged himself in sarcastic allusions in his printed correspondence, in the *Epistle to Dr. Arbuthnot* and in the *Dunciad*. To these Cibber replied with *A Letter from Mr. Cibber to Mr. Pope, inquiring into the motives that might induce him in his satirical works to be so frequently fond of Mr. Cibber's name* (1742). Cibber scored with an "idle story of Pope's behaviour in a tavern" inserted in this letter, and gives an account of the original dispute over the *Rehearsal*. By the substitution of Cibber for Theobald as hero of the *Dunciad* much of the satire lost its point. Cibber's faults certainly did not include dullness. A new edition contained a prefatory discourse, probably the work of Warburton, entitled "Ricardus Aristarchus, or the Hero of the Poem," in which Cibber is made to look ridiculous from his own *Apology*. Cibber replied in 1744 with *Another Occasional Letter . . .*, and altogether he had the best of the argument. When he was 74 years old he made his last appearance on the stage as Pandulph in his own *Papal Tyranny in the Reign of King John* (Covent Garden, Feb. 15, 1745), a miserable paraphrase of Shakespeare's play. He died on Dec. 11, 1757.

Cibber's reputation has suffered unduly from the depreciation of Pope and Johnson. "I could not bear such nonsense" said Johnson of one of Cibber's odes, "and I would not let him read it to the end." Fielding attacked Cibber's style and language more than once in *Joseph Andrews*, and elsewhere. Nevertheless, Cibber possessed wit, unusual good sense and tact; and in the *Apology* he showed himself the most delicate and subtle critic of acting of his time. He was frequently accused of plagiarism, and did not scruple to make use of old plays, but he is said to have been ashamed of his Shakespearian adaptations, one of which, however, *Richard III.* (Drury Lane, 1700), kept its place as the acting version until 1821. Cibber is rebuked for his mutilation of Shakespeare by Fielding in the *Historical Register for 1736*, where he figures as Ground Ivy.

CHARLOTTE, Colley Cibber's youngest daughter, married Richard Charke, a violinist, from whom she was soon separated. She began as an understudy to actresses in leading parts, but quarrelled with her manager, Charles Fleetwood, on whom she wrote a one-act skit, *The Art of Management* (1735). She also wrote two comedies and two novels of small merit, and an untrustworthy, but amusing, *Narrative of Life of . . . Charlotte Charke, . . . by herself* (1755), reprinted in Hunt and Clarke's *Autobiographies* (1822).

The *Apology* was edited in 1822 by E. Bellchambers and in 1889 by R. W. Lowe, who printed with it other valuable theatrical books and pamphlets. It is also included in Hunt and Clarke's *Autobiographies* (1826, etc.). Cibber's *Dramatic Works* were published in 1760, with an account of the life and writings of the author, and again in 1777. Besides the plays already mentioned, he wrote *Woman's Wit, or the Lady in Fashion* (1697), which was altered later (1707) into *The Schoolboy, or the Comical Rivals; Xerxes* (1699), a tragedy acted only once; *The Provoked Husband* (acted 1728), completed from Vanbrugh's unfinished *Journey to London; The Rival Queens, with the Humours of Alexander the Great* (acted 1710), a comical tragedy; *Damon and Phyllida* (acted 1729), a ballad opera; and adaptations from Beaumont and Fletcher, Dryden, Molière and Corneille. A bibliography of the numerous skits on Cibber is to be found in Lowe's *Bibliographical Account of English Theatrical Literature.*

CIBBER, SUSANNAH MARIA (1714–1766), wife of T. Cibber, was an actress of distinction. She was the daughter of a Covent Garden upholsterer, and sister of Dr. Arne (1710–78) the composer. Mrs. Cibber had a beautiful voice and began her career in opera. She was the original Galatea in Handel's *Acis and Galatea*, and the contralto arias in the *Messiah* are said to have been written for her. She played Zarah in Aaron Hill's version of Voltaire's *Zaïre* in 1736, and it was as a tragic actress, not as a singer, that her greatest triumphs were won. From Colley Cibber she learned a sing-song method of declamation. Her mannerisms, however, did not obscure her real genius, and she freed herself from them entirely when she began to act with Garrick, with whom she

was associated at Drury Lane from 1753. She died on Jan. 30, 1766. She married Theophilus Cibber in 1734, but soon separated from him. Appreciations of Mrs. Cibber's fine acting are to be found in many contemporary writers, one of the most discriminating being in the *Rosciad* of Charles Churchill.

CIBBER, THEOPHILUS (1703–1758), Colley Cibber's son; also an actor and playwright, was born on Nov. 26, 1703. In 1734 he was acting-manager at the Haymarket, and later played at Drury Lane, Lincoln's Inn Fields and Covent Garden. His best impersonation was as Pistol, but he also distinguished himself in some of the fine-gentleman parts affected by his father. He was one of the ringleaders in the intrigues against John Highmore, who had bought a share in the patent of Drury Lane from Colley Cibber. Theophilus Cibber, with a number of other actors, seceded from Drury Lane, and in thus depreciating the value of the patent, for which his father had received a considerable sum, acted with doubtful honesty.

In 1753 appeared *An Account of the Lives of the Poets of Great Britain and Ireland*, with the name of "Mr. Cibber" on the title page. The five volumes of *Lives* are chiefly based on the earlier works of Gerard Langbaine and Giles Jacob and the ms. collections of Thomas Coxeter (1689–1747). The book is said to have been largely written by Robert Shiels, Dr. Johnson's amanuensis. Theophilus Cibber perished by shipwreck on his way to Dublin to play at the Theatre Royal.

CIBORIUM, in classical Latin a drinking-vessel (Gr. κιβώριον, the cup-shaped seed-vessel of the Egyptian water-lily, and hence a cup). In the early Christian church the ciborium was a canopy over the altar (*q.v.*), supported on columns, and from it hung the dove-shaped receptacle in which was reserved the consecrated Host. The name was early transferred to the receptacle, and in the Western church the canopy was known as a baldachin (Ital. *baldacchino*, from *Baldacco*, Bagdad, whence came the rich brocade used for canopies, etc.). At the present day in the Roman church the term "pyx" (πύξις, a boxwood vessel) is used for the receptacle in which the viaticum is carried to the sick or dying. Mediaeval pyxes and ciboria are often beautiful examples of the goldsmith's, enameller's and metal-worker's craft. They usually take the shape of a covered chalice or of a cylindrical box with cover surmounted by a cross. An exquisite ciborium, probably of English 13th century make, fetched £6,000 at Christie's in 1908: copper-gilt, ornamented with champlevé enamels, with Biblical subjects in medallions on the outside (coloured illustration in catalogue of Burlington Fine Arts Club Exhibition, 1897).

CIBRARIO, LUIGI, Count (1802–1870), Italian statesman and historian, was born in Usseglia. His verses to King Charles Albert, then prince of Carignano, on the birth of his son Victor Emmanuel, led to a long friendship. He entered the Sardinian civil service, and in 1824 was appointed lecturer on canon and civil law. He was sent to search the archives of Switzerland, France and Germany for charters relating to the history of Savoy. During the war of 1848, after the expulsion of the Austrians from Venice, Cibrario was sent to that city with Colli on an abortive mission to secure its union with Piedmont. After the battle of Novara (1849) and the abdication of Charles Albert he visited the ex-king at Oporto on behalf of the Senate. In May 1852 he became minister of finance in the reconstructed d'Azeglio cabinet, and later minister of education in that of Cavour. He strongly supported Cavour's Crimean policy (1855), and, as minister for foreign affairs during the war, he seconded Cavour in procuring the admission of Piedmont to the congress of Paris on an equal footing with the great powers. On retiring from the foreign office Cibrario was created count. After the war of 1866 by which Austria lost Venetia, Cibrario negotiated the restitution of state papers and art treasures removed by the Austrians from Lombardy and Venetia to Vienna. He died in Oct. 1870, near Salò, on the lake of Garda. His most important work was his *Economia politica del medio evo* (Turin, 1839), popular then, but now of little value. His *Schiavitù e servaggio* (Milan, 1868–69) gave an account of the development and abolition of slavery and serfdom.

His biography has been written by F. Odorici, *Il Conte L. Cibrario* (Florence, 1872).

CICADA (Cicadidae), insects of the homopterous division of the Hemiptera (*q.v.*), generally of large size with the femora of the forelegs spined below, two pairs of large membranous wings and prominent eyes. Cicadas are remarkable for the shrill noise emitted by the males, which has been variously compared to a knife-grinder, scissors-grinder or even a railway whistle, and may be heard in concert at a distance of a quarter of a mile or more. The sound-producing organs are a kind of drum on each side of the base of the abdomen. These drums vibrate by the action of powerful muscles and the sound can be modified by the so-called mirrors or sounding boards. Although no auditory organs are known in the females, the song of the males is regarded as a sexual call.

One of the best-known species is the periodical cicada (*Magicicada septendecim*) of eastern N. America, often known as the 17-year "locust" which appears in great numbers and often causes much concern. It has two races, a 13-year race in the southeastern United States which requires 13 years from egg to adult and a 17-year race in the northeastern United States which requires 17 years from egg to adult. There are 17 different broods of the 17-year race in different parts of the United States and 13 different broods of the 13-year race. Since there is some overlapping of the different broods, some confusion has arisen in the minds of some people in regard to the regularity of this insect. By means of a saw-like instrument the eggs are laid in the twigs of trees, and the nymphs, upon hatching, drop to the ground, where they bury themselves. They feed by sucking juices from the roots of forest and fruit trees and finally change into the so-called "pupae." In the latter stage the insect crawls from the ground, grasps a suitable support and emerges as a full-fledged cicada. In some cases these "pupae" construct curious earthen chimneys wherein they live before turning into adults. The life-histories of cicadas are all very similar. Other common North American species seem to require from one to five years to complete their life histories with a few adults emerging every year. Over 2,000 kinds are known and they are most abundant in the tropics. One species occurs in the southern counties of England, but is rare; 170 species are known in the United States. *See* J. G. Myers, *Insect Singers: a Natural History of the Cicadas* (1929). (Z. P. M.)

CICELY, *Myrrhis odorata* (family Umbelliferae), a perennial herb with a leafy hollow stem, 2 to 3 ft. high, much divided leaves, whitish beneath, a large sheathing base, and terminal umbels of small white flowers, the outer ones only of which are fertile. The fruit is dark brown, long (¾ to 1 in.), narrow and beaked. The plant is a native of central and southern Europe, and is found in parts of England and Scotland in pastures, usually near houses. It has aromatic and stimulant properties and was formerly used as a pot-herb.

CICERO, the name of two families of ancient Rome. It may perhaps be derived from *cicer* (pulse), in which case it would be analogous to such names as *Lentulus, Tubero, Piso*. Of one family, of the plebeian Claudian *gens*, only a single member, Gaius Claudius Cicero, tribune in 454 B.C., is known. The other family was a branch of the Tullii, settled from an ancient period at Arpinum. This family, four of whose members are noticed specially below, did not achieve more than municipal eminence until the time of M. Tullius Cicero, the great orator.

(1) Marcus Tullius Cicero (106–43 B.C.), Roman orator and politician, was born at Arpinum on Jan. 3, 106 B.C. His mother, Helvia, is said to have been of good family. His father was by some said to have been descended from Attius Tullius, the Volscian host of Coriolanus, while spiteful persons declared him to have been a fuller; in any case he was a Roman knight with property at Arpinum and a house in Rome. His health was weak, and he generally lived at Arpinum, where he devoted himself to literary pursuits. Cicero spent his boyhood partly in his native town and partly at Rome. The poet Archias, he says, first inspired him with the love of literature. He was much impressed by the teaching of Phaedrus, the Epicurean, at a period before he assumed the *toga virilis;* he studied dialectic under Diodotus the Stoic, and in 88 B.C. attended the lectures of Philo, the head of the Academic school, whose devoted pupil he became.

He studied rhetoric under Molo (Molon) of Rhodes, and law under the guidance of Q. Mucius Scaevola, the augur and jurisconsult. After the death of the augur, he transferred himself to the care of Q. Mucius Scaevola, the *pontifex maximus*, a still more famous jurisconsult, nephew of the augur. His literary education at this period consisted largely of verse-writing and making translations from Greek authors. We hear of an early poem named *Pontius Glaucus* the subject of which is uncertain, and of translations of Xenophon's *Oeconomica* and the *Phenomena* of Aratus. Considerable fragments of the latter work are still extant. To this period also belongs his *de Inventione rhetorica*, of which he afterwards spoke lightly (*de Orat.* i. 5), but which enjoyed a great vogue in the middle ages. Cicero also, according to Roman practice, received military training. At the age of 17 he served in the social war successively under Pompeius Strabo and Sulla (89 B.C.). In the war between Marius and Sulla his sympathies were with Sulla, but he did not take up arms (*Sext. Rosc.* 136, 142).

His forensic life begins in 81 B.C., at the age of 25. A speech delivered in this year, *pro Quinctio*, is still extant; it is concerned with a technical point of law and has little literary merit. In the following year he made his celebrated defence of Sextus Roscius on a charge of parricide. He subsequently defended a woman of Arretium, whose freedom was impugned on the ground that Sulla had confiscated the territory of that town. He then left Rome on account of his health, and travelled for two years in the East. He studied philosophy at Athens under various teachers, notably Antiochus of Ascalon, founder of the Old Academy, a combination of Stoicism, Platonism and Peripateticism. In Asia he attended the courses of Xenocles, Dionysius and Menippus, and in Rhodes those of Posidonius, the famous Stoic. In Rhodes also he studied rhetoric once more under Molo, to whom he ascribes a decisive influence upon the development of his literary style. He had previously affected the florid, or Asiatic, style of oratory then current in Rome. The chief faults of this were excess of ornament, antithesis, alliteration and assonance, monotony of rhythm, and the insertion of words purely for rhythmical effect. Molo, he says, rebuked his youthful extravagance and he came back "a changed man."

He returned to Rome in 77 B.C., and appears to have married at this time Terentia, a rich woman with a domineering temper, to whom many of his subsequent embarrassments were due.[1] He engaged at once in forensic and political life. He was quaestor in 75, and was sent to Lilybaeum to supervise the corn supply. His connection with Sicily let him to come forward in 70 B.C., when curule-aedile elect, to prosecute Gaius Verres, who had oppressed the island for three years. Cicero seldom prosecuted, but it was the custom at Rome for a rising politician to win his spurs by attacking a notable offender (*pro Caelio*, 73). In the following year he defended Marcus Fonteius on a charge of extortion in Gaul, using various arguments which might equally well have been advanced on behalf of Verres himself.

In 68 B.C. his letters begin, from which (and especially those to T. Pomponius Atticus, his "second self") we obtain wholly unique knowledge of Roman life and history. In 66 B.C. he was praetor, and was called upon to hear cases of extortion. In the same year he spoke on behalf of the proposal of Gaius Manilius to transfer the command against Mithridates from Lucullus to Pompey (*de Lege Manilia*), and delivered his clever but disingenuous defence of Aulus Cluentius (*pro Cluentio*). At this time he was a prospective candidate for the consulship, and was obliged by the hostility of the nobles towards "new men" to look for help wherever it was to be found. In 65 B.C. he even thought of defending Catiline on a charge of extortion, and delivered two speeches on behalf of Gaius Cornelius, tribune in 67 B.C., a leader of the democratic party. In 64 B.C. he lost his father and his son Marcus was born. The optimates finally decided to support him for the consulship in order to keep out Catiline, and he eagerly embraced the "good cause," his affection for which from this time onward never varied, though his actions were not always consistent.

The public career of Cicero henceforth is largely covered by the article on ROME: *Ancient History*. The year of his consulship (63) was one of amazing activity, both administrative and oratorical. Besides the three speeches against Publius Rullus and the four against Catiline, he delivered a number of others, among which that on behalf of Gaius Rabirius is especially notable. The charge was that Rabirius (*q.v.*) had killed Saturninus in 100 B.C., and by bringing it the democrats challenged the right of the senate to declare a man a public enemy. Cicero, therefore, was fully aware of the danger which would threaten himself from his execution of the Catilinarian conspirators. He trusted, however, to receive the support of the nobles. In this he was disappointed. They never forgot that he was a "new man," and were jealous of the great house upon the Palatine which he acquired at this time. Caesar had made every possible effort to conciliate Cicero,[1] but, when all overtures failed, allowed Publius Clodius to attack him. Cicero found himself deserted, and on the advice of Cato went into exile to avoid bloodshed. He left Rome at the end of March 58, and arrived on May 23 at Thessalonica where he remained in the deepest dejection until the end of November, when he went to Dyrrhachium (Durazzo) awaiting his recall. He left for Italy on Aug. 4, 57, and on arriving at Brundisium (Brindisi) found that he had been recalled by a law passed by the *comitia* on the very day of his departure. On his arrival at Rome he was received with enthusiasm by all classes, but did not find the nobles at all eager to give him compensation for the loss of his house and villas, which had been destroyed by Clodius. He was soon encouraged by the growing coolness between Pompey and Caesar to attack the acts of Caesar during his consulship, and after his successful defence of Publius Sestius on March 10 he proposed on April 5 that the senate should on May 15 discuss Caesar's distribution of the Campanian land. This brought about the conference of Luca (Lucca). Cicero was again deserted by his supporters and threatened with fresh exile. He was forced to publish a "recantation," probably the speech *de Provinciis Consularibus*, and in a private letter says frankly, "I know that I have been a regular ass." His conduct for the next three years teems with inconsistencies which we may deplore but cannot pass over. He was obliged to defend in 54 Publius Vatinius whom he had fiercely attacked during the trial of Sestius; also Aulus Gabinius, one of the consuls to whom his exile was due; and Rabirius Postumus, an agent of Gabinius. On the other hand, he made a violent speech in the senate in 55 against Lucius Piso, the colleague of Gabinius in 58. We know from his letters that he accepted financial aid from Caesar, but that he repaid the loan before the outbreak of the civil war. There is no doubt that he was easily deceived. He was always an optimist, and thought that he was bringing good influence to bear upon Caesar as afterwards upon Octavian. His actions, however, when Caesar's projects became manifest, sufficiently vindicated his honesty. During these unhappy years he took refuge in literature. The *de Oratore* was written in 55 B.C., the *de Republica* in 54, and the *de Legibus* at any rate begun in 52. The latter year is famous for the murder of Clodius by T. Annius Milo on the Appian Way (on Jan. 18), which brought about the appointment of Pompey as sole consul and the passing of special laws dealing with rioting and bribery. Cicero took an active part in the trials which followed both as a defender of Milo and his adherents and as a prosecutor of the opposite faction. At the close of the year, to his annoyance, he was sent to govern Cilicia under the provisions of Pompey's law (*see* POMPEY and ROME: *Ancient History*). His reluctance to leave Rome, already shown by his refusal to take a province, after his praetorship and consulship, was increased by the inclination of his daughter Tullia, then a widow, to marry again.

[1] According to Plutarch she urged her husband to take vigorous action against Catiline, who had compromised her half-sister Fabia, a vestal virgin; also to give evidence against Clodius, being jealous of his sister Clodia.

[1] Caesar, at one time, offered him a place on the coalition, which on his refusal became a triumvirate (*Att.* ii. 3. 3; *Prov. Cons.* 41), and afterwards a post on his commission for the division of the Campanian land, or a *legatio libera*.

During his absence she married the profligate spendthrift, P. Cornelius Dolabella.

The province of Cilicia was a large one. It included, in addition to Cilicia proper, Isauria, Lycaonia, Pisidia, Pamphylia and Cyprus, as well as a protectorate over the client kingdoms of Cappadocia and Galatia. There was also danger of a Parthian inroad. Cicero's legate was his brother Quintus Cicero (below), an experienced soldier who had gained great distinction under Caesar in Gaul. The fears of Parthian invasion were not realized, but Cicero, after suppressing a revolt in Cappadocia, undertook military operations against the hill-tribes of the Amanus and captured the town of Pindenissus after a siege of 46 days. A *supplicatio* in his honour was voted by the senate. The early months of 50 were occupied by the administration of justice, chiefly at Laodicea, and by various attempts to alleviate the distress in the province caused by the exactions of his predecessor, Appius Claudius. He had to withstand pressure from influential persons (*e.g.*, M. Brutus, who had business interests in his province), and refused to provide his friends with wild beasts for their games in Rome. Leaving his province on the earliest opportunity, he reached Brundisium on Nov. 24, and found civil war inevitable. He went to Rome on Jan. 4, but did not enter the city, since he aspired to a triumph for his successes. After the outbreak of war he was placed by Pompey in charge of the Campanian coast. After much irresolution he refused Caesar's invitations and resolved to join Pompey's forces in Greece. He was shocked by the ferocious language of his party, and himself gave offence by his bitter jests (Plut. *Cic.* 38). Through illness he was not present at the battle of Pharsalus, but afterwards was offered the command by Cato the Younger at Corcyra, and was threatened with death by the young Cn. Pompeius when he refused to accept it. Thinking it useless to continue the struggle, he sailed to Brundisium, where he remained until Aug. 12, 47, when, after receiving a kind letter from Caesar, he went to Rome. Under Caesar's dictatorship Cicero abstained from politics. His voice was raised on three occasions only: once in the senate in 46 to praise Caesar's clemency to M. Claudius Marcellus (*pro Marcello*), to plead in the same year before Caesar for Quintus Ligarius, and in 45 on behalf of Deiotarus, tetrarch of Galatia, also before Caesar. He suffered greatly from family troubles at this period. In 46. he divorced Terentia, and married his young and wealthy ward, Publilia. Then came the greatest grief of his life, the death of Tullia, his beloved daughter. He shortly afterwards divorced Publilia, who had been jealous of Tullia's influence and proved unsympathetic. To solaçe his troubles he devoted himself wholly to literature. To this period belong several famous rhetorical and philosophical works, the *Brutus, Orator, Partitiones Oratoriae, Paradoxa, Academica, de Finibus, Tusculan Disputations*, together with other works now lost, such as his *Laus Catonis, Consolatio* and *Hortensius*.

His repose was broken by Caesar's murder on March 15, 44, to which he was not a party. On March 17 he delivered a speech in the senate urging a general amnesty like that declared in Athens after the expulsion of the Thirty Tyrants. When it became apparent that the conspirators had removed only the despot and left the despotism, he again devoted himself to philosophy, and in an incredibly short space of time produced the *de Natura Deorum, de Divinatione, de Fato, Cato maior* (or *de Senectute*), *Laelius* (or *de Amicitia*), and began his treatise *de Officiis*. To this period also belongs his lost work *de Gloria*. He then projected a journey to Greece in order to see his son Marcus, then studying at Athens, of whose behaviour he had heard unfavourable reports. He reached Syracuse on Aug. 1, having during the voyage written from memory a translation of Aristotle's *Topica*. He was driven back by unfavourable winds to Leucopetra, and then, hearing better news, returned to Rome on Aug. 21. He was bitterly attacked by Marcus Antonius (Mark Antony) in the senate on Sept. 1 for not being present there, and on the next day replied in his First *Philippic*. He then left Rome and devoted himself to the completion of the *de Officiis*, and to the composition of his famous Second *Philippic*, which was never delivered, but was circulated, at first privately, after Antony had made his departure from Rome on the way to Cisalpine Gaul on Nov. 28.

Cicero returned to Rome on Dec. 9, and from that time forward led the republican party in the senate. His policy, stated briefly, was to make use of Octavian, whose name was all-powerful with the veterans, until new legions had been raised which would follow the republican commanders. Cicero pledged his credit for the loyalty of Octavian, who styled him "father" and affected to take his advice on all occasions. Cicero, an incurable optimist in politics, may have convinced himself of Octavian's sincerity. The breach, however, was bound to come, and the saying, maliciously attributed to Cicero, that Octavian was an "excellent youth who must be praised and—sent to another place," neatly expresses the popular view of the situation. Cicero was sharply criticized by M. Junius Brutus for truckling to Octavian while showing irreconcilable enmity to Antony and Lepidus (*ad Brut.* i. 16. 4, i. 15. 9); but Brutus was safe in his province, and it is difficult to see what other course was open to a politician in Rome. Whether Cicero was right or wrong, none can question his amazing energy. He delivered his long series of Philippics at Rome, and kept up a correspondence with the various provincial governors and commanders, all short-sighted and selfish, and several of them half-hearted, endeavouring to keep each man in his place and to elaborate a common plan of operations. He was naturally included in the list of the proscribed, though it is said that Octavian fought long on his behalf, and was slain near Formiae on Dec. 7, 43. He had a ship near in which he had previously attempted to flee, but being cast back by unfavourable winds he returned to his villa, saying, "Let me die in the country which I have often saved." His head and hands were sent to Rome and nailed to the rostra, after Fulvia, wife of Antony and widow of Clodius, had thrust a hairpin through the tongue.

Works.—The literary works of Cicero may be classed as (i.) rhetorical; (ii.) oratorical; (iii.) philosophical and political; (iv.) epistolary.

(i.) *Rhetorical.*—His chief works of this kind are: (*a*) *de Oratore*, a treatise in three books dedicated to his brother Quintus. The discussion is conducted in the form of a dialogue which is supposed to have occurred in 91 B.C. chiefly between the two orators L. Crassus and M. Antonius. The first book deals with the studies necessary for an orator; the second with the treatment of the subject matter; the third with the form and delivery of a speech. Cicero says of this work in a letter (*Fam.* i. 9. 23) that it "does not deal in hackneyed rules and embraces the whole theory of oratory as laid down by Isocrates and Aristotle." (*b*) *Brutus*, or *de claris oratoribus*, a history of Roman eloquence containing much valuable information about his predecessors, drawn largely from the *Chronicle* (*liber annalis*) of Atticus. (*c*) *Orator*, dedicated to M. Brutus, sketching a portrait of the perfect and ideal orator, Cicero's last word on oratory. The sum of his conclusion is that the perfect orator must also be a perfect man. Cicero says of this work that he has "concentrated in it all his taste" (*Fam.* vi. 18. 4). The three treatises are intended to form a continuous series containing a complete system of rhetorical training.

It will be convenient to mention here a feature of Ciceronian prose on which singular light has been thrown by recent inquiry. In the *de Oratore*, iii. 173 *sqq.*, he considers the element of rhythm or metre in prose, and in the *Orator* (174–226) he returns to the subject and discusses it at length. His main point is that prose should be metrical in character, though it should not be entirely metrical, since this would be poetry (*Orator*, 220). Greek writers relied for metrical effect in prose on those feet which were not much used in poetry. Aristotle recommended the paean ⏑⏑⏑–. Cicero preferred the cretic –⏑–, which he says is the metrical equivalent of the paean. Demosthenes was especia fond of the cretic. Rhythm pervades the whole sentence but is most important at the end or *clausula*, where the swell of the period sinks to rest. The ears of the Romans were almost incredibly sensitive to such points. We are told that an assembly

was stirred to wild applause by a double trochee – ∪ – ∪.[1] If the order were changed, Cicero says, the effect would be lost. The same rhythm should be found in the *membra* which compose the sentence. He quotes a passage from one of his own speeches in which any change in the order would destroy the rhythm. Cicero gives various *clausulae* which his ears told him to be good or bad, but his remarks are desultory as also are those of Quintilian, whose examples were largely drawn from Cicero's writings. It was left for modern research to discover rules of harmony which the Romans obeyed unconsciously. Other investigators had shown that Cicero's *clausulae* are generally variations of some three or four forms in which the rhythm is trochaic. Dr. Thaddaeus Zielinski of Warsaw, after examining all the *clausulae* in Cicero's speeches, finds that they are governed by a law. In every *clausula* there is a basis followed by a cadence. The basis consists of a cretic or its metrical equivalent.[2] This is followed by a cadence trochaic in character, but varying in length. The three favourite forms are (i.) – ∪ – ⏑, (ii.) – ∪ – – ∪ ⏑, (iii.) – ∪ – – ∪ – ⏑. These he styles *verae* (V). Other frequent *clausulae*, which he terms *licitae* (L), are those in which a long syllable is resolved, as in verse, into two shorts, e.g., *ēssĕ vĭdēātŭr*. These two classes, V and L, include 86% of the *clausulae* in the orations. Some rarer *clausulae* which he terms M (=*malae*) introduce no new principle. There remain two interesting forms, viz., S (=*selectae*), in which a spondee is substituted for a trochee in the cadence, e.g., – ∪ – – – ⏑, this being done for special emphasis, and P (= *pessimae*), where a dactyl is so used, e.g., ∪ – – ∪ ∪ ⏑, this being the *heroica clausula* condemned by Quintilian. Similar rules apply to the *membra* of the sentence, though in these the S and P forms are more frequent, harmony being restored in the *clausula*.

These results apply not only to the speeches but also to the philosophical writings and the more elaborate letters, and with modifications to other rhythmical prose, *e.g.*, that of Pliny and Seneca. Rhythm was avoided by Caesar who was an Atticist, and by Sallust, who was an archaist. Livy's practice is exactly opposite to that of Cicero, since he has a marked preference for the S forms, thereby exemplifying Cicero's saying that long syllables are more appropriate to history than to oratory (*Orator*, § 212).

(ii.) *Speeches.*—These were generally delivered before the senate or people, if political in character, and before jurors sitting in a *quaestio*, if judicial. The speech against Vatinius was an attack upon a witness under examination; that *de Domo* was made before the Pontifices; that *pro C. Rabirio perduellionis reo* in the course of a *provocatio* to the people; and those *pro Ligario* and *pro rege Deiotaro* before Caesar. The five orations composing the *Actio Secunda in Verrem* were never spoken, but written after Verres had gone into exile. The Second *Philippic* also was not delivered but issued as a pamphlet. Cicero's speech for Milo at his trial was not a success, though, as Quintilian (ix. 2. 54) quotes from it, as taken down by shorthand reporters, an example of a rhetorical figure well used, it cannot have been such a failure as is alleged by later writers. The extant speech was written by Cicero at his leisure. None of the other speeches is in the exact form in which it was delivered. Cicero's method was to construct a *commentarius* or skeleton of his speech, which he used when speaking. If he was pleased with a speech he then wrote it out for publication. Sometimes he omitted in the written speech a subject on which he had spoken. A record of this is sometimes preserved: *e.g.*, "de Postumi criminibus" (*Mur.* 51), "de teste Fufio" (*Cael.* 19). These *commentarii* were published by his freedman Tiro and are quoted by Asconius (*ad Orat. in Toga Candida*, p. 87).

Cicero in his speeches must be given all the privileges of an advocate. Sometimes he had a bad client; he naïvely confesses the straits to which he was put when defending Scamander (*Clu.* 51; *cf. Phil.* xiii. 26). He thought of defending Catiline, though he says that his guilt is clear as noon-day (*Att.* i. 1–2 and ii. 1). Sometimes the brief which he held at the moment compelled him to take a view of facts contrary to that which he had previously advocated. Thus in the *pro Caecina* he alleges judicial corruption against a witness, Falcula, while in the *pro Cluentio* he contends that the offence was not proved (*Caec.* 28, *Clu.* 103). He says quite openly that "it is a great mistake to suppose that statements in his speeches express his real opinions" (*Clu.* 139). It is therefore idle to reproach him with inconsistencies, though these are sometimes very singular. Thus in the *pro Cornelio* he speaks with praise of Gabinius, who, when a colleague vetoed his proposal, proceeded to depose him after the precedent set by Tiberius Gracchus (Asconius *in Cornel.* p. 71). In the *pro Cluentio*, 111, he contends that nothing is easier than for a new man to rise at Rome. In the *pro Caelio* he says that Catiline had in him undeveloped germs of the greatest virtues, and that it was the good in him that made him so dangerous (*Cael.* 12–14). He sometimes deliberately puts the case upon a wrong issue. In the *pro Milone* he says that either Milo must have lain in wait for Clodius or Clodius for Milo, leaving out of sight the truth, that the encounter was due to chance. He used to boast that he had cast dust into the eyes of the jury in the case of Cluentius (Quintil. ii. 17–21).

Cicero had a perfect mastery of all weapons wielded by a pleader in Rome. He was specially famous for his pathos, and for this reason, when several counsel were employed, always spoke last (*Orat.* 130). A splendid specimen of pathos is to be found in his account of the condemnation and execution of the Sicilian captains (*Verr.* [*Act.* ii.] v. 106–122). Much exaggeration was permitted to a Roman orator. Thus Cicero frequently speaks as if his client were to be put to death, though a criminal could always evade capital consequences by going into exile. His enemies scoffed at his "tear-drops." He indulged in the most violent invective, which, though shocking to a modern reader, *e.g.*, in his speeches against Vatinius and Piso, was not offensive to Roman taste (*de Orat.* ii. 216–290). He was much criticized for his jokes, and even Quintilian (ii. 17–21) regrets that he made so many in his speeches. He could never resist the temptation to make a pun. It must be remembered, however, that he was the great wit of the period. Caesar used to have a collection of Cicero's *bons mots* brought to him. Cicero complains that all the jokes of the day were attributed to himself, including those made by very sorry jesters (*Fam.* vii. 32. 1). A fine specimen of sustained humour is to be found in his speech *pro Murena*, where he rallies the jurisconsults and the Stoics. He was also criticized for his vanity and perpetual references to his own achievements. His vanity, however, as has been admirably remarked, is essentially that of "the peacock, not of the gander," and is redeemed by his willingness to raise a laugh at his own expense (Strachan-Davidson, p. 192). Some critics have impugned his legal knowledge, but probably without justice. It is true that he does not claim to be a great expert, though a pupil of the Scaevolas, and when in doubt would consult a jurisconsult; also, that he frequently passes lightly over important points of law, but this was probably because he was conscious of a flaw in his case.

(iii.) *Political and Philosophical Treatises.*—These are generally written in the form of dialogues, in which the speakers sometimes belong to bygone times and sometimes to the present. The first method was known as that of Heracleides, the second as that of Aristotle (*Att.* xiii. 19. 4). There is no reason to suppose that the speakers held the views with which Cicero credits them, or had such literary powers as would make them able to express such views (*ib.*, xiii. 12. 3). The political works are *de Republica* and *de Legibus*. The first was a dialogue in six books concerning the best form of constitution, in which the speakers are Scipio Africanus Minor and members of his circle. He tells us that he drew largely from Plato, Aristotle, Theophrastus and writings of the Peripatetics. The famous "Dream of Scipio" recalls the "Vision of Er" in Plato's *Republic* (Book x. *ad fin.*). The *de*

[1] *Orator*, § 214: "'patris dictum sapiens temeritas fili cōmprŏbāvit'—hoc dichoreo tantus clamor contionis excitatus est ut admirabile esset. Quaero, nonne id numerus efficerit? Verborum ordinem immuta, fac sic: 'Comprobavit fili temeritas' jam nihil erit."

[2] This theory is partly anticipated by Terentianus Maurus (*c.* A.D. 290), who says of the cretic (v. 1440 *sqq.*):—

"Plurimum orantes decebit quando paene in ultimo
Obtinet sedem beatam, terminet si clausulam
Dactylus spondeus imam, nec trochaeum respuo;
Plenius tractatur istud arte prosa rhetorum."

Legibus, a sequel to this work in imitation of Plato's *Laws*, is drawn largely from Chrysippus.

Cicero as a philosopher belonged to the New Academy. The followers of this school were free to hear all arguments for and against, and to accept the conclusion which for the moment appeared most probable (*Acad.* ii. 131). Thus in the *Tusculan Disputations* v. he expresses views which conflict with *de Finibus* iv., and defends himself on the ground that as an Academic he is free to change his mind. He was much fascinated by the Stoic morality, and it has been noticed that the *Tusculan Disputations* and *de Officiis* are largely Stoic in tone. He has nothing but contempt for the Epicureans, and cannot forgive their neglect of literary style. As Cicero's philosophical writings have been severely attacked for want of originality, it is only fair to recollect that he resorted to philosophy as an anodyne when suffering from mental anguish, and that he wrote incredibly fast. He issued two editions of his *Academica*. The first consisted of two books, in which Catulus and Lucullus were the chief speakers. He then rewrote his treatise in four books, making himself, Varro and Atticus the speakers. His works are confessedly in the main translations and compilations (*Att.* xii. 52. 3); all that he does is to turn the discussion into the form of a dialogue, to adapt it to Roman readers by illustrations from Roman history, and to invent equivalents for Greek technical terms. This is equally true of the political treatises. Thus, when Atticus criticized a strange statement in *de Republ.* ii. 8, that all the cities of the Peloponnese had access to the sea, he excuses himself by saying that he found it in Dicaearchus and copied it word for word (*Att.* vi. 2. 3). In the same passage he used an incorrect adjective, *Phliuntii* for *Phliasii;* he says that he had already corrected his own copy, but the mistake survives in the single palimpsest in which this work has been preserved. The only merits, therefore, which can be claimed for Cicero are that he invented a philosophical terminology for the Romans, and that he produced a series of manuals which from their beauty of style have had enduring influence upon mankind.

The most famous of these treatises are the following:

De Finibus, on the Supreme Good. In Book i. L. Manlius Torquatus explains the Epicurean doctrine, which is refuted in ii. by Cicero. In iii. and iv. M. Porcius Cato sets forth the doctrine of the Stoics which is shown by Cicero to agree with that of Antiochus of Ascalon; in v. M. Pupius Piso explains the views of the Academics and Peripatetics.

Tusculanae Disputationes, so called from Cicero's villa at Tusculum in which the discussion is supposed to have taken place. The subjects treated are:—in Book i., the nature of death and the reasons for despising it; Book ii., the endurance of pain; pain is not an evil; Book iii., wisdom makes a man insensible to sorrow; Book iv., wisdom banishes all mental disquietude; Book v., virtue is sufficient to secure happiness. The materials are drawn largely from works of Dicaearchus.

De Deorum Natura.—The dialogue is placed in 77 B.C. In Book i. Velleius attacks other philosophies and explains the system of Epicurus. He is then refuted by Cotta. In Book ii. Balbus, speaking as a Stoic, discusses the existence of the gods, nature, the government of the world and providence. In Book iii. Cotta criticizes the views of Balbus. The statement of the Epicurean doctrine is drawn from the work of Phaedrus, *περὶ θεῶν* the criticism of this from Posidonius. The Stoic teaching is derived from Cleanthes, Chrysippus and Zeno, and is criticized from the writings of Carneades and Clitomachus.

De Officiis, addressed to his son Marcus. In this the form of dialogue was not employed. The material is chiefly drawn from Stoic sources, *e.g.*, works of Panaetius in Books i. and ii., of Posidonius and Hecato in Book iii.

The *Academica*, as they have come down to us, are a conflation from the two editions of this work. They consist of the second book from the first edition, and a portion of the first book from the second edition.

Cato maior, or *de Senectute*, a dialogue placed in 150 B.C., in which Cato, addressing Scipio and Laelius, set forth the praises of old age. The idea is drawn from Aristo of Chios, and the materials largely derived from Xenophon and Plato.

Laelius, or *de Amicitia*, a dialogue between Laelius and his sons-in-law, in which he sets forth the theory of friendship, speaking with special reference to the recent death of Scipio. Cicero here draws from a work of Theophrastus on the same subject and from Aristotle.

(iv.) *Letters.*—Those preserved are (1) *ad Familiares*, i.–xvi.; (2) *ad Atticum*, i.–xvi.; (3) *ad Quintum*, i.–iii., *ad Brutum*, i.–ii. Some 35 other books of letters were known to antiquity, *e.g.*, to Caesar, to Pompey, to Octavian and to his son Marcus.

The collection includes nearly 100 letters written by other persons. Thus, the eighth Book *ad Fam.* consists entirely of letters from Caelius to Cicero when in Cilicia. When writing to Atticus Cicero frequently sent copies of letters which he had received. There is a great variety in the style not only of Cicero's correspondents, but also of Cicero himself. Caelius writes in a breezy, school-boy style; the Latinity of Plancus is Ciceronian in character; the letter of Sulpicius to Cicero on the death of Tullia is a masterpiece of style; Matius writes a most dignified letter justifying his affectionate regard for Caesar's memory. Several of his correspondents are indifferent stylists. Cato labours to express himself in an awkward and laconic epistle, apologizing for its length. Metellus Celer is very rude, but gives himself away in every word. Antony writes bad Latin, while Cicero himself writes in various styles. We have such a *cri de coeur* as his few words to one of the conspirators after Caesar's murder, "I congratulate you. I rejoice for myself. I love you. I watch your interest; I wish for your love and to be informed what you are doing and what is being done" (*Fam.* vi. 15). When writing to Atticus he eschews all ornamentation, uses short sentences, colloquial idioms, rare diminutives and continually quotes Greek This use of Greek tags and quotations is also found in letters to other intimate friends, *e.g.*, Paetus and Caelius; also in letters written by other persons, *e.g.*, Cassius to Cicero; Quintus to Tiro, and subsequently in those of Augustus to Tiberius. It is a feature of the colloquial style and often corresponds to the modern use of "slang." Other letters of Cicero, especially those written to persons with whom he was not quite at his ease or those meant for circulation, are composed in his elaborate style with long periods, parentheses and other devices for obscuring thought. These are throughout rhythmical in character, like his speeches and philosophical works.

We know from Cicero's own statement (*Att.* xvi. 5. 5) that he thought of publishing some of his letters during his lifetime. On another occasion he jestingly charges Tiro with wishing to have his own letters included in the "volumes" (*Fam.* xvi. 17. 1). It is obvious that Cicero could not have meant to publish his private letters to Atticus in which he makes confessions about himself, or those to Quintus in which he sometimes outsteps the limits of brotherly criticism, but was thinking of polished productions such as the letters to Lentulus Spinther or that to Lucceius which he describes as "very pretty" (*Att.* iv. 6. 4).

It is universally agreed that the letters *ad Familiares* were published by Tiro, whose hand is revealed by the fact that he suppresses all letters written by himself, and modestly puts at the end those written to him. That Cicero kept copies of his letters, or of many of them, we know from a passage in which, when addressing a friend who had inadvertently torn up a letter from him, he says that there is nothing to grieve about; he has himself a copy at home and can replace the loss (*Fam.* vii. 25. 1). Tiro may have obtained from Terentia copies of letters written to her. It has been suggested that he may also have edited the letters to Quintus, as he could obtain them from members of the family. The letters *ad Familiares* were generally quoted in antiquity by books, the title being taken from the first letter, *e.g.*, *Cicero ad Varronem epistula Paeti.*

While the letters *ad Familiares* were circulated at once, those to Atticus appear to have been suppressed for a considerable time. Cornelius Nepos (*Att.* 16) knew of their existence but distinguishes them from the published letters. Asconius (p. 87), writing under Claudius, never quotes them, though, when discussing Cicero's projected defence of Catiline, he could hardly have

failed to do so, if he had known them. The first author who quotes them is Seneca. It is, therefore, probable that they were not published by Atticus himself, who died 32 B.C., though his hand may be seen in the suppression of all letters written by himself, but that they remained in the possession of his family and were not published until about A.D. 60. At that date they could be published without expurgation of any kind, whereas in the letters *ad Familiares* the editor's hand is on one occasion (iii. 10. 11) manifest. Cicero is telling Appius, his predecessor in Cilicia, of the measures which he is taking on his behalf. There then follows a lacuna. It is obvious that Tiro thought the passage compromising and struck it out. In the letters to Atticus, on the other hand, we have Cicero's private journal, his confessions to the director of his conscience, the record of his moods from day to day, without alterations of any kind.

Cicero's letters are the chief and most reliable source of information for the period. It is due to them that the Romans of the day are living figures to us, and that Cicero, in spite of, or rather in virtue of his frailties, is intensely human and sympathetic. The letters to Atticus abound in the frankest self-revelation, though even in the presence of his confessor his instinct as a pleader makes him try to justify himself. The historical value of the letters, therefore, completely transcends that of Cicero's other works. It is true that these are full of information. Thus we learn much from the *de Legibus* regarding the constitutional history of Rome, and much from the *Brutus* concerning the earlier orators. The speeches abound in details which may be accepted as authentic, either because there is no reason for misrepresentation or on account of their circumstantiality. Thus the *Verrines* are our chief source of information for the government of the provinces, the system of taxation, the powers of the governor. They tell us of the monstrous system by which the governor could fix upon a remote place for the delivery of corn, and so compel the farmer to compound by a payment in money which the orator does not blame, on the ground that it is only proper to allow magistrates to receive corn wherever they wish (iii. 190). From the speech *pro Cluentio* (145–154) we gain unique information concerning the condition of society in a country town, the extraordinary exemption of *equites* from prosecution for judicial corruption, the administration of domestic justice in the case of slaves examined by their owner (*ib.*, 176–187). But we have always to be on our guard against misrepresentation, exaggeration and falsehood. The value of the letters lies in the fact that in them we get behind Cicero and are face to face with the other *dramatis personae;* also that we are admitted behind the scenes and read the secret history of the times. One of the most interesting documents in the correspondence is a despatch of Caesar to his agent Oppius, written in great haste and in disjointed sentences. It runs as follows: "On the 9th I came to Brundisium. Pompey is at Brundisium. He sent Magius to me to treat of peace. I gave him a suitable answer" (*Att.* ix. 13, A). In the *de Bello civili,* on the other hand, Caesar who wishes to show that he did his best to make peace, after stating that he sent his captive Magius to negotiate, expresses mild surprise at the fact that Pompey did not send him back (*Bell. Civ.* i. 26). We hear of the extraordinary agreement made by two candidates for the consulship in Caesar's interest with the sitting consuls of 54 B.C., which Cicero says he hardly ventures to put on paper. Under the terms of this the consuls, who were *optimates,* bound themselves to betray their party by securing, apparently fraudulently, the election of the candidates while they in turn bound themselves to procure two ex-consuls who would swear that they were present in the senate when supplies were voted for the consular provinces, though no meeting of the senate had been held, and three augurs who would swear that a *lex curiata* had been passed, though the *comitia curiata* had not been convened (*Att.* iv. 18. 2). But perhaps the most singular scene is the council of three great ladies presided over by Servilia at Antium, which decides the movements of Brutus and Cassius in June 44 B.C., when Cassius "looking very fierce—you would say that he was breathing fire and sword"—blustered concerning what he considered an insult, viz., a commission which had been laid upon him to supply corn. Servilia calmly remarks she will have the commission removed from the decree of the senate (*Att.* xv. 11. 2).

(v.) *Miscellaneous.*—It is not necessary to dwell upon the other forms of literary composition attempted by Cicero. He was a fluent versifier, and would write 500 verses in one night. Considerable fragments from a juvenile translation of Aratus have been preserved. His later poems upon his own consulship and his exile were soon forgotten except for certain lines which provoked criticism, such as the unfortunate verse:

"O fortunatam natam me consule Romam."

He wrote a memoir of his consulship in Greek and at one time thought of writing a history of Rome. Nepos thought that he would have been an ideal historian, but as Cicero ranks history with declamation and on one occasion with great *naïveté* asks Lucius Lucceius (*q.v.*), who was embarking on this task, to embroider the facts to his own credit, we cannot accept this criticism (*Fam.* vi. 2. 3).

(vi.) *Authenticity.*—The genuineness of certain works of Cicero has been attacked. It was for a long time usual to doubt the authenticity of the speeches *post reditum* and *pro Marcello.* Recent scholars consider them genuine. As their rhythmical structure corresponds more or less exactly with the canon of authenticity formed by Zielinski from the other speeches, the question may now be considered closed. Absurd suspicion has been cast upon the later speeches *in Catilinam* and that *pro Archia.* An oration *pridie quam in exsilium iret* is certainly a forgery, as also a letter to Octavian. There is a "controversy" between Cicero and Sallust which is palpably a forgery, though a quotation from it occurs in Quintilian (iv. 1. 68). Suspicion has been attached to the letters to Brutus, which in the case of two letters (i. 16 and 17) is not unreasonable since they somewhat resemble the style of *suasoriae,* or rhetorical exercises, but the latest editors, Tyrrell and Purser, regard these also as genuine.

After Cicero's death his character was attacked by various detractors, such as the author of the spurious *Controversia* put into the mouth of Sallust, and the calumniator from whom Dio Cassius (xlvi. 1–28) draws the libellous statements which he inserts into the speech of Q. Fufius Calenus in the senate. Of such critics, Asconius (in *Tog. Cand.* p. 95) well says that it is best to ignore them. His prose style was attacked by Pollio as Asiatic, also by his son, Asinius Gallus, who was answered by the emperor Claudius (Suet. 41). The writers of the silver age found fault with his prolixity, want of sparkle and epigram and monotony of his *clausulae.* A certain Largius Licinius gained notoriety by attacking his Latinity in a work styled *Ciceromastix.* His most devoted admirers were the younger Pliny, who reproduced his oratorical style with considerable success, and Quintilian (x. 1. 112), who regarded him as the perfect orator, and draws most of his illustrations from his works. At a later period his style fascinated Christian writers, notably Lactantius, the "Christian Cicero," Jerome and St. Augustine, who drew freely from his rhetorical writings.

(2) QUINTUS TULLIUS CICERO, brother of the orator and brother-in-law of T. Pomponius Atticus, was born about 102 B.C. He was aedile in 67, praetor in 62, and for the three following years propraetor in Asia, where, though he seems to have abstained from personal aggrandizement, his ill-temper gained him an evil notoriety. After his return to Rome, he heartily supported the attempt to secure his brother's recall from exile, and was nearly murdered by gladiators in the pay of Clodius. He distinguished himself as one of Julius Caesar's legates in the Gallic campaigns, served in Britain, and afterwards under his brother in Cilicia. On the outbreak of the Civil War between Pompey and Caesar, Quintus, like Marcus, supported Pompey, but after Pharsalus he deserted and made peace with Caesar, largely owing to the intercession of Marcus. Both the brothers fell victims to the proscription which followed Caesar's death, Quintus being put to death in 43, some time before Marcus. His marriage with Pomponia was very unhappy, and he was much under the influence of his freedman Statius. Though trained on the same lines as Marcus he never spoke in public, and even said,

"One orator in a family is enough, nay even in a city." Though essentially a soldier, he took considerable interest in literature, wrote epic poems, tragedies and annals, and translated plays of Sophocles. There are extant four letters written by him (one to his brother Marcus, and three to his freedman Tiro) and a short paper, *de Petitione Consulatus* (on canvassing for the consulship), addressed to his brother in 64. A few hexameters by him on the 12 signs of the zodiac are quoted by Ausonius.

(3) MARCUS TULLIUS CICERO, only son of the orator and his wife Terentia, was born in 65 B.C. At the age of 17 he served with Pompey in Greece and commanded a squadron of cavalry at the battle of Pharsalus. In 45 he was sent to Athens to study rhetoric and philosophy, but abandoned himself to a life of dissipation. It was during his stay at Athens that his father dedicated the *de Officiis* to him. After the murder of Caesar (44) he attracted the notice of Brutus, by whom he was offered the post of military tribune, in which capacity he rendered good service to the Republican cause. After the battle of Philippi (42), he took refuge with Sextus Pompeius in Sicily, where the remnants of the Republican forces were collected. He took advantage of the amnesty granted by the Treaty of Misenum (39) to return to Rome, where he took no part in public affairs, but resumed his former dissipated habits. In spite of this, he received signal marks of distinction from Octavian, who not only nominated him augur, but accepted him as his colleague in the consulship (30). He had the satisfaction of carrying out the decree which ordered that all the statues of Antony should be demolished, and thus "the divine justice reserved the completion of Antony's punishment for the house of Cicero" (Plutarch). He was subsequently appointed proconsul of Asia or Syria, but nothing further is known of his life. In spite of his debauchery, there is no doubt that he was a man of considerable education and no mean soldier, while Brutus, in a letter to his father (*Epp. ad Brutum*, ii. 3), even goes so far as to say that the son would be capable of attaining the highest honours without borrowing from the father's reputation.

(4) QUINTUS TULLIUS CICERO (*c.* 67–43 B.C.), son of Quintus Tullius Cicero (brother of the orator). He accompanied his uncle Marcus to Cilicia, and, in the hope of obtaining a reward, repaid his kindness by informing Caesar of his intention of leaving Italy. After the battle of Pharsalus he joined his father in abusing his uncle as responsible for the condition of affairs, hoping thereby to obtain pardon from Caesar. After the death of Caesar he attached himself to Mark Antony, but, owing to some fancied slight, he deserted to Brutus and Cassius. He was included in the proscription lists, and was put to death with his father in 43. In his last moments he refused under torture to disclose his father's hiding-place. His father, who in his concealment was a witness of what was taking place, thereupon gave himself up, stipulating that he and his son should be executed at the same time.

BIBLIOGRAPHY.—It is impossible to mention more than a few works as the literature is so vast. (1) *Historical.*—J. L. Strachan-Davidson, *Cicero and the Roman Republic* (Heroes of the Nations series, 1894); G. Boissier, *Cicéron et ses amis* (1865); W. Warde Fowler, *Social Life at Rome* (1908); introduction to R. Y. Tyrrell and L. C. Purser's edition of the letters (1904–18); Th. Ziclinski, *Cicero im Wandel der Jahrhunderte* (3rd ed., Leipzig, 1912). (2) *Literary.*—M. CICERO, a town of Cook county, Ill., U.S., about 7 mi. S.W. of the loop, and bounded by Chicago on the north, east and south. Pop. (1950) 67,195; (1940) 64,712 by the federal census. Cicero is an important industrial centre, manufacturing electrical equipment, iron and steel, enamelware, castings, asbestos, copper, brass and printing machinery. Cicero was settled about 1849, and was incorporated in 1867. The town achieved notoriety during the 1920s and later as the headquarters of Alphonse ("Scarface Al") Capone (1899–1947) and other Chicago gangsters who built vast criminal syndicates to run speak-easies during the period of prohibition and later expanded their activities along many other lines, principally gambling and prostitution.

CICERONE, a guide, one who conducts visitors to museums, galleries, etc., and explains matters of historic or artistic interest. The word is presumably taken from Marcus Tullius Cicero as a type of learning and eloquence. According to a quotation (1762) cited by the *New English Dictionary* the word seems first to have been applied to "learned antiquarians who show and explain to foreigners the antiquities and curiosities of the country."

CICHLID. The fishes of the family Cichlidae are perches with a single nostril on each side and with the lower pharyngeals coalesced or united by suture. They are found in lakes, rivers and brackish lagoons of Central and South America, Africa and Syria, Madagascar and India. This distribution was formerly considered to favour the idea of the persistence of the connection between South America and Africa into the Eocene, but the value of the Cichlids in this relation is discounted by the fact that many species enter brackish water and some the sea. Their presence in Madagascar, where none of the true freshwater African families is represented, indicates that their dispersal has been accomplished in a manner different from these.

The American species number about 250, the African 400; none of the genera is common to the two continents. The Indian *Etroplus* is an isolated genus, related only to *Paretroplus* of Madagascar, in which island the genera are peculiar, the two others being related to African genera. In the African Cichlid fauna an extraordinary diversity and specialization is attained in the great lakes, Tanganyika having 100 species, nearly all belonging to genera found only in the lake, and Nyassa having nearly as many endemic species, some of which have evolved on parallel lines to those of Tanganyika. The lacustrine genera differ from each other, especially in modifications of the mouth and teeth, enabling these fishes to make use of every kind of animal and vegetable food available in the lakes. Many Cichlids are beautifully coloured, and are favourite aquarium fishes. *Hericlithys cyanoguttatus* of Mexico, covered with bright blue spots, is one of the really handsome species. *Pterophyllum scalare* of the Amazon has the body very deep and strongly compressed and the dorsal and anal fins high. *Tilapia nilotica*, the bolti of the Nile, reaches a length of 18 inches.

In many Cichlids the female fish keeps the eggs in her mouth until they hatch, and for a time swims with her brood, opening her mouth for the little fishes to swim in when danger threatens. In other species the eggs are laid in a hollow scooped out by the male; both parents guard the nest until the eggs hatch, when the mother takes the young into her mouth. (C. T. R.)

CICISBEO (chĭ-chĭs-bā'ō), the term in Italy (17th century onwards) for a dangler about women. The cicisbeo was the professed gallant of a married woman, who attended her at all public entertainments, it being considered unfashionable for the husband to be her escort.

CICOGNARA, LEOPOLDO, COUNT (1767–1834), Italian archaeologist and writer on art, was born at Ferrara. A residence of some years at Rome, devoted to the study of the antiquities and galleries, was followed by visits to Naples and Sicily. He then visited Florence, Milan, Bologna and Venice, acquiring a complete archaeological knowledge of these and other cities. In 1795 he took up his abode at Modena, and was for 12 years engaged in politics, becoming minister plenipotentiary of the Cisalpine Republic at Turin. Napoleon decorated him with the Iron Crown; and in 1808 he was made president of the Academy of the Fine Arts at Venice. In 1808 appeared his treatise *Del bello ragionamenti*. This was followed (1813–18) by his *magnum opus*, the *Storia della scultura dal suo risorgimento in Italia al*

secolo di Napoleone. The book was designed to complete the works of Winckelmann and D'Agincourt, and is illustrated with 180 plates in outline. His *Fabbriche più cospicue di Venezia,* two superb folios containing about 150 plates, was published (1815–20) under the auspices of Francis I of Austria. Charged by the Venetians with the presentation of their gifts of the empress Caroline at Vienna, Cicognara added to the offering an illustrated catalogue of the objects it comprised; this book, *Omaggio delle Provincie Venete alla maestà di Carolina Augusta,* has since become of great value to the bibliophile. In 1821 he published at Pisa a *catalogue raisonné,* rich in bibliographical lore, of his fine library, the result of 30 years of loving labour, which in 1824 was purchased *en bloc* by Pope Leo XII and added to the Vatican library. Cicognara's work in the academy at Venice, of which he became president in 1808, led to the foundation of a gallery for the reception of Venetian pictures.

See Zanetti, *Cenni biografici di Leopoldo Cicognara* (Venice, 1834); Malmani, *Memorie del conte Leopoldo Cicognara* (Venice, 1888).

CICONIIDAE: *see* JABIRU; STORK.

CID, THE (Arabic *sid,* "lord"), is the popular sobriquet by which RODRIGO DÍAZ DE VIVAR (?1043–1099), most famous of mediaeval Spanish captains, has been known in Spain since his own day. It is frequently linked with another sobriquet, of Romance origin, *Campeador,* "winner of battles." There is a substantial heroic history of Rodrigo Díaz, in both poetry and prose, originating in the 12th century, but this is of more concern to the student of literature than to the historian (*see* SPANISH LITERATURE). There are, however, some acceptable historical sources from which his biography may be established. These include some contemporary documents, the *Historia Roderici* (a very nearly contemporary private Latin chronicle of his life) and a detailed narrative of his conquest of Valencia written by Ibn Alkama, an Arab historian living in the city at the time.

Rodrigo Díaz was born at Vivar, near Burgos, about 1043, his father, Diego Laínez, being a member of the Castilian squirearchy. He was brought up at the court of Ferdinand I by the latter's eldest son, Sancho. Details of his early career are uncertain, but he seems to have distinguished himself in Ferdinand's later campaigns and, when Sancho succeeded to the Castilian throne (1065), the young Cid was appointed to the high military office of standard-bearer. His successful generalship during Sancho's reign established his military reputation.

The Cid had taken a prominent part in the campaign which enabled Sancho to seize the throne of León from his younger brother, Alphonso. His position was, therefore, of some difficulty when Sancho was killed at the siege of Zamora (1072) and Alphonso returned from exile to become king of both León and Castile. Nevertheless, he remained at Alphonso's court for nearly a decade and, in 1074 even married the king's own niece, Jimena, daughter of the count of Oviedo. In 1079 the Cid was with the army of Alphonso's tributary, Mutamid (al-Motamid) of Seville, when Mutamid defeated an invasion by Abdullah of Granada. Alphonso's favourite, Count García Ordoñez, happened to be on the Granadine side and was captured by the Cid. This affair renewed Alphonso's dormant suspicions of him, and when it was followed, in 1081, by an unauthorized incursion on a large scale into the Moorish kingdom of Toledo, over which Alphonso had established a protectorate, the Cid was ordered into exile.

He now removed himself to the Moorish kingdom of Saragossa, whose kings he served for a number of years, leading successful campaigns on their behalf against the count of Barcelona (1082) and Sancho Ramírez of Aragon (1084). He also became chief political adviser to his Moorish employers (who regarded him highly) and acquired that familiarity with Islamic politics, law and customs which was to prove invaluable for his later career.

A temporary reconciliation with Alphonso in 1083 had soon broken down, but the king's difficulties in meeting the invasion of Spain by the Almorávides led him to readmit the Cid to his favour in 1087. The Cid's interests were by this time wholly concentrated on eastern Spanish affairs, and he turned his attention to the task of securing Alphonso's suzerainty over the extensive Moorish kingdom of Valencia. In 1089 he extracted a written assurance from Alphonso that any lands won by him from the Moors would belong to himself and his heirs in perpetuity. When, later in the same year, he was again banished, he proceeded with the subjugation of Valencia more or less as a private venture.

The conquest of Valencia by the Cid was an extremely complicated affair: it began in 1089, when he made its king, al-Kadir, his tributary; entered its second stage in 1092, when al-Kadir was murdered by the cadi Ibn Yehhaf; and ended in June 1094, when the city capitulated to the Cid's troops after a prolonged siege. During these proceedings, the Cid relied on his talent for political intrigue almost as much as on military force, playing off against each other both the rival groups within the city and his own rivals for its control outside it—Alphonso himself, the Almorávides and the king of Saragossa. Several months after the surrender the Cid broke the terms of the capitulation that he had made with Ibn Yehhaf and executed him in a brutal manner; motives of cupidity and vengeance were responsible, at least in part, for this act. Determined Almorávide attempts to recover the city were defeated by the Cid at the battles of Cuarte (1094) and of Bairén (1097). The semiroyal status that the former squire from Vivar had by now achieved was shown when, soon afterward, his daughters Cristina and María married the Navarrese prince Ramiro and Raymund Berenguer, count of Barcelona, respectively.

The Cid died in Valencia on July 10, 1099. Three years later his wife, Jimena, had to give up the city, as it was impossible to hold it indefinitely against the Almorávides. The Cid's body was removed to the monastery of San Pedro de Cardeña, near Burgos, where the monks gradually made it the centre of an elaborate cult which sought to portray the Cid as a near saint.

The task of evaluating the Cid's career historically is a delicate one because of his status as a national hero. It is clear from all sources that he was a remarkably successful field commander, consistently achieving brilliant victories over superior enemy forces by boldness in action balanced, however, by cunning and careful preparation. There is little evidence of any religious motive behind his career, particularly before the coming of the Almorávides. The force which drove him seems to have been the pursuit of power and wealth. In these respects his attitude was entirely typical of that of other Christian Spaniards in pre-Almorávide Spain. The truth behind his quarrels with Alphonso VI is uncertain, but it would be rash to absolve the Cid of all blame by attributing responsibility to that exceptionally able monarch. The deeds of the Cid cannot be said to have made any great material contribution to Spanish history: he did not take part in Alphonso's most critical campaigns; his greatest achievement, the conquest of Valencia, proved ephemeral.

Nevertheless the Cid's life fired the popular imagination as that of no other mediaeval Spaniard was able to do. This was the result not only of his invincibility in the field but also of the fact that, after his career as a courtier had been ruined, he had continued to win fame, riches and rank solely by the exercise of his sword and his intelligence despite the king's disapproval and the active opposition of the great magnates.

Sunderland, *The Cid and His Spain* (London, 1934). The text of the *Historia Roderici Campidocti* is published by Menéndez Pidal, *op. cit.,* ii, pp. 919–969, and by R. Foulché-Delbosc in the *Revue hispanique,* xxi (Paris, 1909). For Ibn Alkama's account of the conquest of Valencia, *see* E. Lévi-Provençal, "La Toma de Valencia por el Cid," *Al-Andalus,* xiii (Madrid, 1948). (P. E. R.)

CIDER or CYDER is an alcoholic beverage made from apples; it is produced by the vinous fermentation of the expressed juice of the fruit. (In the United States the name is applied also to the unfermented juice.) Although any kind of apples can be used for the purpose, special vintage varieties distinguished by chemical and other characters rendering them unsuited for the most part for table use are required for a beverage of fine quality. The making of cider has been attempted wherever the apple is grown extensively, but a flourishing commercial industry has been established only where true vintage fruit can be obtained.

The Cider Districts.—The cider apple orchards of the world are mainly confined to certain districts of France and England.

The former country possesses the largest acreage and ranks as the chief producing centre, its average annual output of fruit being sufficient to permit of a considerable export trade to adjacent countries after home requirements have been satisfied. The cider orchards of France are chiefly concentrated in Normandy and Brittany, where the soil and other local conditions are particularly well suited to the production of fruit of a high order of vintage quality. The average annual output of cider in France is roughly 40,000,000 gal. In England, where the acreage under cider fruit is also extensive, the orchards are almost entirely confined to the western and southwestern counties, in particular Hereford, Worcester, Gloucester, Monmouth, Somerset and Devon. In that area, according to the returns of the ministry of agriculture and fisheries, the extent of grass orcharding is approximately 50,000 ac., of which the major part is planted with cider apple trees. Cider fruit growing has also spread into the counties bordering that area. In other parts of Great Britain the cider industry is limited to a few scattered localities, of which parts of Norfolk, Suffolk and Kent are the most important. Efforts have been made to develop the industry in Ireland with some success, but in this case the quantity of fruit grown specially for the purpose is small. The cider-making industry in Germany has attained considerable dimensions, but it has been in the past to some extent dependent on supplies of imported French fruit. Of the other European countries, Spain and Switzerland notably have obtained repute.

Farm Cider and Factory Cider.—While in France and Germany the cider industry has long been of considerable commercial importance and the manufacture of the beverage has been carried on in factories of some magnitude, in England before the beginning of the 20th century cider making was chiefly confined to the farms upon which the fruit was grown. The product was mainly consumed on the farm and the surplus disposed of in the immediate locality. Except for the output of a few old-established factories the distribution and consumption of cider were confined almost exclusively to the west of England. Thereafter there was a remarkable change. The introduction of improved methods of making as the result of research and education aided by the ministry of agriculture led to a marked improvement in the quality of the article placed upon the market, which was followed by the widespread adoption of cider as a popular beverage throughout the country generally. Many new factories in the cider-making area were established and the major part of the fruit which was formerly made into cider on the farms was now sold by the farmers to the factories. There was a gradual elimination of making on farms where the product was formerly indifferently prepared.

Legal Standards.—As a commercial article English cider has been handicapped by its extreme variability in character. No legal definitions or standards have been imposed other than regulations relating to metallic contamination and the National Mark Scheme for Cider introduced in World War II. A wide variety of types has therefore been placed upon the market. In France, where hitherto the industry has been of much greater commercial importance, cider has to conform to a series of regulations defining the respective standards of the beverage to which the name may be applied. These regulations, originally introduced in 1905 and modified in 1933, lay down that no beverage may be offered for sale under the name of cider unless produced exclusively by the fermentation of the juice from fresh apples, or a mixture of fresh apples and pears extracted with or without the addition of potable water. The term *cidre pur jus* is reserved for cider made without addition of water. The term *cidre* may be applied only to a beverage containing at least 3.2% (weight by volume) alcohol actual or potential, 1.3% (wt./vol.) dry extract at 100° C. (sugar not included) and 0.13% (wt./vol.) ash (apart from any salt added as a specific treatment). All ciders containing smaller quantities must be designated as *boisson de pommes*.

In England, though no corresponding regulations exist, the application of the name of cider to beverages other than those of which apple juice is the basis is an offense under the Merchandise Marks acts, as illustrated by cases where legal proceedings have been taken successfully against the use of the name for synthetic carbonated drinks flavoured with artificial apple essence.

Constituents of Cider.—Even in the most strictly restricted class, that of *cidre pur jus*, the French regulations permit a great elasticity in the nature of the beverage offered for sale. The primary reason for variability lies in the nature of the raw material. The more important constituents of apple juice are sugars, malic acid and "tannin." (The term "tannin" is used comprehensively by cider makers to include a group of constituents giving an astringent and bitter flavour to the juice; chemically they may not all be true tannins.) If allowance is made for seasonal effects on composition and the kinds of apples used and no account is taken of extreme cases, the total sugar content of a freshly expressed juice may range from 6% to 20%, the acid from 0.1% to 1.25% and the tannin from 0.05% to 0.75%. Further, since the extent of the ensuing fermentation is related to the nitrogenous content of the juice, which also varies widely, it proceeds in some cases till the whole of the sugar is fermented (unless prevented by special treatment), and in others ceases prematurely and leaves more or less of the sugars unfermented. According to the nature of the juice used, therefore, the finished article may be sweet or dry, strongly or very lightly alcoholic, highly acid or of a very low grade of acidity and strongly astringent and bitter or almost entirely lacking in that character.

The variations here indicated are attributable primarily to the varieties of apples from which the juice is derived. By a suitable blending of different sorts, juices of any desired standard of composition can be secured. In practice individual makers aim at definite standards suited to the taste of their customers and some degree of uniformity is thus attained, but as the predominating kinds of apples grown in different areas vary widely and other local influences, such as those of soil and climate, come into play, ciders tend to show marked distinctive local characters. French ciders generally are characterized by low acidity and a bittersweet flavour. Those of the English cider area north of Bristol are usually light and brisk as compared with the typical heavy subacid and bittersweet Somerset ciders and the less heavy but luscious Devon type of rather low acidity and astringency.

Classification and Composition of Cider Apples.—The varieties of cider apples are grouped into three classes, commonly termed sharp, sweet and bittersweet respectively. The classification is based upon chemical composition. The sharp class includes all varieties yielding the juices which normally contain not less than 0.45% of total acid, expressed as malic acid. The latter is the predominating acid, but various other organic acids are also present in very small amounts. Varieties of the sweet class are characterized by juices containing normally less than 0.45% of total acid, expressed as malic acid, and also less than 0.2% of tannin. Bittersweet apples contain normally in their juices acids in corresponding amount to those of the sweet class and are specially characterized by a relatively large quantity of tannin, which normally exceeds 0.2%.

According to this classification all table varieties of apples, dessert and culinary, fall within the sharp class and form a distinct section of it characterized by an extremely low tannin content, which rarely exceeds 0.1% in the juice. The typical sharp vintage apple contains generally a substantially larger amount. This high-acid, low-tannin character of the eating apple and other features usually associated with that type of composition render such fruit inferior for cider making, primarily because of the unbalanced flavour of the product. The number of varieties of cider apple occurring in the orchards of England and France is very large, certainly running into thousands. Many are of very low vintage quality and are being eliminated gradually in favour of those proved by research and experience to be worthy of more extended cultivation. A complete list of the latter is too lengthy for inclusion here, but the following selection is representative of high-grade English and French varieties.

ENGLISH VARIETIES. *Sharp*—Backwell Red, Coleman's Seedling, Crimson King, Frederick, Kingston Black, Improved Foxwhelp, Langworthy, Stoke Red. *Sweet*—Court Royal, Sweet Alford, Sweet Coppin. *Bittersweet*—Ashton Brown Jersey, Belle Norman, Brown Snout, Bulmer's Norman, Dabinett, Dove, Ellis Bitter, Hangdown, Kingston Bitter, Red Jersey, Tremlett's Bitter, White Norman, Yarlington Mill.

FRENCH VARIETIES. Bédan, Binet Rouge, Doux Amer, Ecarlatine, Frequin Audièvre, Frequin Rouge, Michelin, Muscadet, Reine des Pommes, Reinette Obry, Tardive Forestier.

Cider Making.—Methods of cider making have undergone great changes since the early years of the 19th century. Then the fruit was crushed to a pulpy mass by heavy revolving stone rollers in a circular stone trough, similar to a mortar mill, and the pulp transferred by shovels to a cumbrous wooden press worked by hand, the time occupied in milling and pressing a single lot of fruit often extending to more than 24 hours. The modern grater form of mill now in general use is a steel cylindrical revolving drum in which are fixed toothed knives in such fashion that their edges project about $\frac{1}{16}$ in. above the surface of the drum. The latter is power driven at 2,000 r.p.m. The fruit falling upon it is grated almost instantaneously to a very fine pulp from which, because of its extreme state of disintegration, the juice can be expressed with great ease and speed. This pulp, technically termed pomace, is delivered from the mill direct onto the bed of the press, where it is built up into a "cheese," consisting of a series of layers, each wrapped in an open-meshed cloth or net of cotton or other strong fibre and separated from its neighbours by slatted wooden racks to facilitate the drainage of the juice. Power-driven hydraulic presses have now largely superseded the old screw type. Later types of mill, such as the hammer, are, moreover, considered in some respects to represent an advance on the grater. With machinery of this type the whole series of operations can be completed within 20 minutes after the delivery of the fruit to the mill. With fruit in good condition, a yield of juice varying from 75% to 80% of the weight of the fruit can be obtained.

Juice extracted by this method is comparatively clear and free from fragments of pulp and can therefore be placed directly into fermenting vats or casks without any intervening treatment being required to remove the suspended solid matter. The operation of keeving, formerly an important stage in the clearing of the juice, is thus no longer necessary and the risk of taint from acetic fermentation greatly reduced.

In some factories a diffusion process, analogous to that used in the extraction of sugar from sugar beet, is substituted for that of direct expression of the juice by pressure.

Subsequent treatment is determined by the type of cider to be produced. If a sweet cider is required, the fermenting juice must be filtered at a comparatively early stage to make it possible to retain the desired percentage of unfermented sugar. If a dry cider is wanted, fermentation is allowed to proceed till the whole or the greater part of the sugar is converted into alcohol. Filtration is then required for the purpose of clarifying the liquor rather than for checking fermentation. Various types of filters are in use. They differ in constructional details rather than in principle, which consists of the forcing under pressure of the turbid liquor through a thick layer of paper pulp or other suitable fibrous material. In many cases a single filtration suffices to clear the cider to a brilliant condition; occasionally for sweet ciders a second filtration is necessary to prevent further fermentation. Many makers use a centrifuge beforehand to facilitate filtration. After filtration the cider is fit for consumption at any time, though age, within limits, brings improvement in flavour. Made by the process here outlined, cider generally requires filtration within three months of the time of milling and is in its best condition for consumption during the summer following making. Specialized forms of treatment are sometimes practised for the production of a more fully matured article, which may require two or three years to reach prime condition.

While there is still a wide demand for draught cider, bottled cider has grown greatly in popularity. The latter is usually conditioned by carbonation, although natural conditioning by the champagne process is utilized for ciders of the highest quality.

Cider Disorders and Preservatives.—Attempts have been made to eliminate the risks of various bacterial disorders by pasteurization of the freshly expressed juice and subsequent fermentation by added pure cultures of selected kinds of yeasts; and some measure of success has been achieved. Most makers, however, still adhere to the older method of natural fermentation resulting from the wild yeasts naturally present on the surface of the apples and rely on strict attention to cleanliness at all stages of production to minimize the risks of disorders. The practice of washing the fruit in running water prior to milling is being increasingly adopted to ensure the maximum of cleanliness.

The chief disorders to which cider is subject are acetification, ropiness, lactic fermentation and "sickness," each caused by specific microorganisms, and discoloration, attributable generally to contamination with iron. To check fermentation and prevent the development of bacterial disorders preservatives such as salicylic acid were formerly largely used. Under the regulations relating to the use of preservatives in foods and drinks which came into force in Great Britain in 1927 no preservative other than sulphur dioxide is permissible for cider. The maximum allowed is 14 gr. of free and combined sulphur dioxide per gallon.

General.—The wholesome properties of pure cider are widely recognized. In affections of a gouty or rheumatic nature positive benefit frequently results and regular cider drinkers are rarely troubled by stone, gravel and similar disorders. The malic acid of cider is regarded as a powerful diuretic which stimulates the kidneys and prevents accumulation of uric acid within the system.

The improved position of the cider industry and the marked developments in technique have been greatly assisted by the researches and educational work on the subject conducted in France at the Station Pomologique at Caen, in Germany and in Switzerland at the research stations of Geisenheim-am-Rhein and of Wädenswil respectively, and in England at the National Fruit and Cider institute established at Long Ashton, near Bristol, and now associated with the University of Bristol.

Charley (London, 1949); Ministry of Agriculture and Fisheries, *Bulletin No. 104: Cider Apple Production* (H.M.S.O., London, 1953). (B. T. P. B.)

UNITED STATES

There is confusion in the United States about the proper terminology for unfermented and fermented juices of the apple. In contrast with European practice cider in the U.S. refers to unfermented juice of the apple. Unfermented apple juice is commonly called cider or fresh cider in contrast with the fermented product, hard cider. The processing industry, however, usually refers to unfermented juice containing less than 0.5% alcohol, by volume, as apple juice, regardless of its method of preservation.

Ordinarily, apple juice is made from second-grade or cull fruit. The apples must be free from decay and worms and must be properly ripened. To obtain an apple juice of high flavour it is important to blend several varieties of apples together to get the proper balance between aroma, acids, sugars and astringent components of the fruit. For example, a typically good blend for apple juice would be 50% Baldwin, 25% Northern Spy, 12½% Cortland and 12½% Russet apples.

Apples to be made into juice must be inspected so that decayed and seriously damaged fruits can be graded out. The fruit is thoroughly washed in water. When spray residues are a problem the apples must be washed in a hot acid or alkaline wash and rinsed with water to reduce the residues below the legal tolerances.

The apples are ground up in grater mills or hammer mills so that pressing can be facilitated. If a juice with the natural colour and flavour is desired a solution of ascorbic acid (vitamin C) is sprayed on the milled pomace before pressing. More commonly, normal oxidation is allowed to take place so that the juice has an amber colour.

The ground pomace is then pressed out in rack-and-cloth types of presses. The ground pulp is placed in layers about two to three inches deep within cloths. These enclosures of pulp, called "cheeses," are built up one on top of the other and separated by wooden racks. A hydraulic press then expresses the juice out of the pomace or pulp. Usually only a single pressing is made but occasionally the pomace is broken up and pressed again under a

higher pressure press. The average yield of juice from apples is about 150 gal. of juice per ton of fruit from the first pressing and 20 gal. per ton from the second pressing. The pomace is ordinarily dried for later processing for pectin extraction.

A considerable amount of apple juice is consumed in the cloudy state in which it comes from the presses. The juice in any case is usually allowed to stand in settling tanks for a short time or is screened to remove the large cell masses. There has been a strong trend toward more clarification than is possible with a simple sedimentation process or screening in order to get a clear product.

Clarification accomplishes a breaking up of the colloidal system of the juice. One of the most widely used systems is the addition of pectin-decomposing enzymes. The enzyme preparation is mixed with the juice and is allowed to stand for several hours or more before the clarified juice is siphoned off. Apple juice is also clarified by using precipitating agents such as gelatin in combination with tannin. The colloidal material may also be removed by mixing the juice with fuller's earth or bentonite clay. Flash heating the juice to 180° F. for about 20 seconds followed by rapid cooling has been used as a means of clarification.

To get complete removal of suspended material from clarified apple juice it is necessary to filter or centrifuge after clarification. Filtration is not always done, however. When clarification is fairly complete, passing the juice through a porous filter composed of diatomaceous earth will give a brilliantly clear juice. If unclarified juice is to be filtered it must be passed through successively retentive filters. High-speed centrifuging may be used prior to filtration on unclarified juice to prevent clogging of the filters. Filtration is carried out in a plate-and-frame type of filter under pressure. After filtration the apple juice may or may not be fortified with ascorbic acid (vitamin C) to make it comparable to citrus juices in nutritional value.

Practically all of the apple juice is preserved by flash pasteurization. Microorganisms are killed by pasteurizing the juice at 170° to 200° F. for one to three minutes. The juice is packaged in sterile cans or bottles. For highest quality juice, freezing is the best method of preservation. The juice is frozen at 0° to −40° F. and stored at 0° F. in tin containers allowing 10% room for expansion in the container during freezing. Some juice is preserved by using chemicals such as sodium benzoate (0.1% dissolved in a small amount of water). Such juice can be kept for a month at room temperature but some flavour is usually imparted by such chemicals. Apple juice is sometimes sterilized by special filters which actually remove yeasts and other microorganisms that cause spoilage. Only highly clarified juices can be sterilized by filtration and sterile conditions must prevail in the packaging rooms.

Apple juice concentrate has the advantage over many other forms of apple juice in that there is a more natural flavour and there are considerable savings in container, shipping and storage costs. Low-temperature evaporation of the water out of the juice is accomplished by using vacuum and boiling off the water at less than 150° F. In another process an apple essence is prepared by concentrating the volatile fractions of the apple juice up to 150 times that of the original juice. Apple juice can also be concentrated by freezing followed by centrifuging.

CIENFUEGOS (originally FERNANDINA DE JAGUA), third largest commercial city of Cuba, on the southern coast, 192 mi. by rail S.E. of Havana in the province of Las Villas (formerly named Santa Clara province). Population of the *municipio* (1943 census), 94,810, 52,910 of whom live in Cienfuegos. Area of *municipio*, 598 sq.mi.

The city, located on a broad, level peninsula opposite the narrow entrance of the magnificent Bay of Jagua or Cienfuegos, is noted for its wide, straight streets, beautiful parks, attractive buildings and scenic surroundings. It is served by the United Railways of Havana and is connected by a branch road with the Central highway of Cuba. Domestic and foreign air lines use its airfield.

The fertile country which surrounds Cienfuegos produces henequen, coffee, rice, tobacco, honey, fruit (especially mangoes and avocados), cattle and large quantities of sugar. Large sugar *centrales* (estates) are located within short distances of the city, such as the *central* Soledad, where Harvard university long maintained botanical gardens for research in tropical agriculture; but the major centres of sugar cultivation are located elsewhere.

The site of Cienfuegos was visited by Columbus in 1494, but the Bay of Jagua and its environs attracted no permanent settlement until 1738, in which year a small fortress (converted into the fort of Nuestra Señora de los Angeles de Xagua in 1745) was erected at the entrance of the port. In 1817 a French colonel from Louisiana (Luis d'Clouet) presented to the captain general of Cuba (Don José Cienfuegos) a project for colonizing the Bay of Jagua. In the same year the foundation of the colony of Fernandina de Jagua was authorized by royal order. D'Clouet, accompanied by 46 colonists, arrived from Bordeaux, Fr., on April 8, 1819; in 1820, 282 more colonists arrived. A poll in 1824 revealed that there were 1,238 inhabitants in the settlement. After a storm had destroyed the village in 1825 it was rebuilt and named Cienfuegos in honour of the man who had participated so actively in its founding.

(R. W. RD.; X.)

CIEZA, a town of southeastern Spain, in the province of Murcia, on the Madrid-Cartagena railway, and junction for a line to Valencia. Pop. (1950) 23,328 (mun.). Cieza stands on the right bank of the Segura river, in a narrow bend of the valley which is enclosed on the north by mountains, providing good building stone and low timber, and on the south broadens into a fertile plain, producing grain, wine, olives, raisins, esparto, oranges and other fruits. The district greatly developed with improved communications, and Cieza became a flourishing town with flour, paper, sawmilling industries and brandy distilleries.

CIEZA DE LÉON, PEDRO DE (*c.* 1519–1560), Spanish soldier and historian, was born at Seville. He sailed for the new world, possibly in Heredia's expedition of 1532, more probably with Duran in 1534, reaching Cartagena in November. In 1535 he went with Heredia's brother Alonzo to Darien, and in 1538 with Vadillo on an appalling journey up the valley of the Cauca; Vadillo was eventually deserted by his men, and Cieza de León later joined Jorge de Robledo, who consolidated the discoveries in the Cauca valley, and on his death served under Belalcazar, governor of Popayan, who had beheaded Robledo. It was in 1541, in the Cauca valley, that he started his diary. In 1547 the troops from Popayan marched to join President Gasca against Pizarro a long journey, the details of which he carefully noted. In 1549 he went to look at the mines of Porco and Potosí, and then to Cuzco to confer with a surviving descendant of the Incas; in 1550 he left for Spain. The first part of his *Crónica de Perú* was published at Seville in 1553.

The scheme of his *Crónica de Perú* was as follows: part i, geography; part ii, early history; part iii (lost), conquest; and part iv (of which books 1, 2 and 3 have been found), civil wars. The first part is a minute topographical review, founded on his diary, with an account of the customs and religion of the people as he found them, given with unusual accuracy of observation and without concealing his respect for the Inca civilization. Part ii, referred to inaccurately by Prescott as *Sarmiento*, gives the history of Peru under the Incas. The manuscript was preserved in the Escorial library and published in 1880.

C.I.F., in commerce, a short form of "cost, insurance, freight." Thus, if an article is quoted C.I.F. London it means that the quotation is inclusive of (1) the price of the article, (2) the cost of insurance to London and (3) the cost of freight to London. In the official trade returns of the United Kingdom the import values are usually recorded by the customs statistical department at C.I.F. values.

CIGAR. The word cigar is derived from the Spanish *cigarro*, which in turn probably was derived from Mayan *sik'ar*, found commonly by early explorers in Cuba and Yucatan. Indians rolled single leaves or wrapped tobacco in its own leaf or in leaves of other plants and understood curing and fermentation of the leaf to improve taste. The industry was carried by the Spaniards to Haiti about 1530 and later to Europe and North America. Early production in the colonies consisted mostly of "Spanish" cigars,

the leaf being obtained in the West Indies trade. Stogies were made as early as 1785 by the Pennsylvania Dutch in York county and were carried west by drivers of Conestoga wagons, from which the name was derived. Connecticut in 1810 established factories making Long Nines and Windsor Particulars, which were peddled by farmers' wives. Imports of cigars from New Orleans in 1800, as well as from Cuba, were part of the same trade pattern. Sizes and shapes of cigars were irregular, often tied in bunches which were sold for a few pennies, or bundled in lots of 100 and packed in barrels and chests.

Composition.—Three components—filler, binder and wrapper—are found in cigars. Filler tobacco is grown in Cuba, Puerto Rico, Pennsylvania and Ohio. Binders are produced in Connecticut, Massachusetts and Wisconsin; wrappers in Connecticut, Florida, Cuba and Indonesia. Havana cigars are made entirely from Cuban tobacco.

Processing.—The cured leaf as received from the farms needs to be sweated, or fermented, before use in the cigar, to reduce the content of harsh and bitter compounds and develop the mild and aromatic properties. Wrapper leaves, tied in hands of 40–50 leaves, are placed in orderly piles, or bulks, of several thousand pounds in a regulated atmosphere. Heat is generated by the tobacco, whereupon the bulk is taken apart and rebuilt, often five or six times. Two subsequent fermentations, the first in wooden cases, the second in bales, precede its use in cigars. Binders are usually packed in wooden cases, placed in a sweat room near 100° F. for several weeks, stored under cooler conditions for nearly a year and sometimes after being remoistened briefly exposed to high temperature and humidity. Fillers, likewise packed in wooden cases, undergo a slow fermentation for one to several years, then are moistened, repacked and submitted to a moist hot atmosphere (about 110° F. with 60% relative humidity). This resweat is interrupted periodically by unpacking and airing the leaves, an operation which may be repeated only once or twice or as many as 10 or 12 times. The severity of fermentation is greatest for fillers, least for wrappers.

How Cigars Are Made.—Whereas early cigar making was entirely by hand, machines now perform most of the steps. In hand work, the midribs, or stems, are removed from the moistened leaves, the half leaves being laid in pads or strips. Strips of filler are bunched to the necessary size and shape and cut evenly on a block with a half-round knife. The binder is cut in a half-moon shape, within which the filler is evenly and smoothly rolled. The wrapper is usually cut narrower than the binder, care being taken to wrap the cigar spirally so that the diagonal veins in the leaf lie lengthwise along the cigar. Opposite diagonal wrapping of binder and wrapper is practised for the right-hand and left-hand halves of the leaves. Finally, for sealing the mouth end or head of the wrapper tragacanth, a product of Iran, is customarily used as an adhesive.

Long hardwood moulds, originally made in Osnabrück, Ger., in 1870, are used in the manufacture of moulded or shaped cigars. This semihand-making or German method is used in the smaller factories for lower-priced cigars. Each matrix holds 20 bunches of hand prepared filler and binder. In team work, trios of cigarmakers are employed, two to wrap and one to break and bind the bunches and load the moulds, each team making approximately 1,000 cigars a day.

Cigar machines were first used in 1919 at Newark, N.J. Later improvements enabled machines to make up to 13 cigars a minute, an approximate rate of 600 to 700 an hour being common. One person feeds the strip filler, the second feeds the binder mechanism, the third feeds the wrapper and the fourth inspects the finished product, which is automatically cut, rolled and pasted. Nearly any size or shape can be produced. Long filler cigars (filler strips the length of the cigar), which command slightly higher prices, scrap filler and ribbon filler are all machine made.

Banding and Packing.—Bands are placed on the cigar or printed on the protective covering (usually cellophane) which preserves the natural humistatic condition of the cigar; this is accomplished by a machine at the rate of 30,000 cigars daily, with band, cellophane, tin foil or any combination of similar wrapping. One person operates the machine.

Boxes of wood, metal, paper and glass are used to package the cigars. Selectors and packers, working under proper lighting, arrange the cigars according to colour and perfection of wrappers. The top row of each box of flat four-row packs is shaded almost imperceptibly to please the eye. Colours commonly recognized are claro (light yellow), colorado claro (light red or brown), colorado (brown), colorado maduro (dark brown), maduro (deep brown), oscuro (almost black). During the McKinley era dark cigars were generally preferred, and experts still believe them to be mildest and tastiest, because the so-called lighter, and particularly the greenish, colours may be bitter. Modern opinion favours the claro shades. Actually, the thin elastic sheen of the wrapper, especially of shade-grown Connecticut, has little influence on smoking quality. As a rule, wrappers have a neutral taste and are selected more for beauty and service than for smoking value. The smoker looks for a pleasant aroma, delicate blend, even burn and white ash.

Terms descriptive of shape of cigars still follow the Spanish nomenclature, as do many brand names. These include straight shapes, such as Londres or London, blunt on the tuck or lighting end; perfecto, pointed at both ends; concha, small perfecto; puritano, adaptation of the perfecto; panatela, long and thin; breva, short and stubby; corona, thick and straight; imperiale, long perfecto; and numerous modifications.

Factory Equipment.—Technological advances in cigar factories cover a wide range. Hand stemming had largely disappeared by mid-20th century. Threshed, cut and shredded filler was prepared to size by rapid machine cutters. Equipment for drying and moistening the leaf, exact control of fermentation processes, and mechanical conveyors and hoists improved the ease of handling and increased the uniformity of the product. Fluorescent lighting with tubes of differing colour permit accurate and constant evaluation of leaf colours. Both from the viewpoint of the product and the workers, it is desirable to keep the air at a proper temperature and moisture content. Air-conditioning equipment and electrostatic precipitrons combine to provide the desired conditions. Precautions for the health and safety of the employees are numerous and effective. Delicate control equipment of laboratory precision is commonly used. Machines are also used for pasting revenue stamps and labels on every box, for attaching special wrappers (commonly used for the Christmas trade), as well as for packaging for shipment.

Research.—Chemical research made great strides, beginning in 1930 in the biochemistry laboratory of the Connecticut Agricultural Experiment station under H. B. Vickery. Specialized analytical methods showed that during curing, rapid starvation of leaf cells was succeeded by extensive breakdown of pigments, leaf proteins and carbohydrates. Basic knowledge thus gained was applied to widely separated plant phenomena. R. F. Dawson made use of tomatoes grown on tobacco roots and the opposite combination (technically known as reciprocal grafts). The leaves and fruit of tomatoes grown on tobacco roots contained nicotine; tobacco plants grown on tomato roots contained no nicotine. By this classic method, he showed that tobacco roots made nicotine and the leaves stored it. Later the laboratory of the General Cigar company under W. G. Frankenburg studied the changes occurring in tobacco during fermentation. Further breakdown of some components affected by curing occurred, but new chemical groups related to colour and aroma were also involved. The relation of low nicotine content to high smoking quality was shown, followed by proof of the breakdown of nicotine into a wide variety of products.

Production.—In the United States, cigar production first passed the 1,000,000,000 mark in 1870; successive increases of 1,000,000,000 occurred in 1879, 1882, 1890, 1900 and 1902. The 7,000,000,000 mark was reached in 1906, but it was not until 1920 that the all-time high of 8,266,770,593 occurred. The decline which became evident in 1921 reached its full impetus in the 1930s, falling below 5,000,000,000. After 1940 a moderate but quite steady increase occurred with consumption in the 1950s approximately 6,000,000,000. (O. E. S.)

Great Britain and Europe.—Though the connoisseur favours Havana- or Jamaican-made cigars as the ideal smoke, there are, nevertheless, many discriminating cigar smokers who are satisfied with the best-quality British-made cigars, which, so far as flavour and aroma are concerned, are little below the imported article and have the advantage of lower price. They are, in fact, manufactured of all-Havana leaf of good quality and are hand-made, their lower price being the result of the difference in customs duty on imported manufactured cigars and the unmanufactured leaf imported by the British manufacturers. Cheaper domestic cigars are made of Sumatra, Borneo, Java, Brazilian and Jamaican leaf, with or without Havana fillers or wrappers according to price. No detailed statistics were made available of sales or production of domestic cigars, but they were considerably lower after than they were before World War II. That the reason for this was high prices was borne out by the enormous increase in the sales of miniature cigars, or whiffs, which suggested that the taste for the cigar-type of smoke was still prevailing and that only the high price held the public back. Whiffs are machine-made; some are all-Havana, others part-Havana. Most of the big manufacturers were breaking sales records each year in the early 1950s.

On the continent of Europe the domestic cigar is a good deal cheaper than in Great Britain because of the lower import duties on leaf tobacco. The Dutch are big cigar manufacturers and use mostly East Indian and Brazilian leaf, which were so cheap that they could export to Great Britain, pay the manufacturers' import rate of duty and still sell at less than many British brands. They were gaining in popularity in Britain in the mid-1950s, not only because of price but also because of their mildness. Germany also is a cigar-smoking nation and has a big domestic production, using mostly East Indian and some domestic-grown leaf. In the mid-1950s German manufacture barely met home consumption. The basis of most continental cigar brands is East Indian, Brazilian and some Havana leaf. (D. SG.)

CIGARETTE. A cigarette is literally a little cigar—finely cut tobacco rolled in paper. The word is undoubtedly from the Spanish *cigarito*, which was introduced to Europe after 1518, when Spaniards found Aztecs wrapping tobacco in cornhusks. The use of cigarettes spread to all parts of Europe, including Turkey and Russia. A great popularity in England followed the Crimean War, but in the United States cigarettes were virtually unknown before 1860.

The U.S. Cigarette Industry.—Early manufacture in the United States was entirely by hand, either in factories or by the smoker (the "roll-your-own" method). The paper was often any type available, but later it was imported from France, where linen was reworked for this purpose. Equipment in early factories was extremely simple. Essentially the process consisted of hand-rolling on a table followed by pasting and hand-packaging. In 1883 girls working in these factories earned a maximum of $9 for rolling 15,000 to 18,000 cigarettes per week. The tobacco was reduced to granules or flakes by hand-crushing or beating before use.

The first shredding or cutting machine was patented in 1860 by W. H. Pease, but was not widely used for many years. A crude cigarette-manufacturing machine was exhibited at the Philadelphia Centennial exposition in 1876. In 1880 James A. Bonsack patented a cigarette machine with several basic features. The prepared tobacco was fed onto a continuous strip of paper which entered a forming tube. In the tube the paper formed a cylinder, passing a pasting brush before being closed. A rotary cutting knife was activated by differential gears to permit intermittent action, and cut the cigarette into the proper length. In 1884 a printing attachment was added. Each of these crude machines did the work of about 50 hand-rollers, approaching 100,000 cigarettes per day, and reduced the cost of manufacture from 80 to 30 cents per 1,000. Production increased from 500,000,000 cigarettes in 1880 to 1,000,000,000 in 1885 and 4,000,000,000 in 1895.

Consumer preference for tobacco products thereafter shifted enormously. Plug or chewing tobacco and snuff were dominant in 1850, while pipe smoking reached its peak in the next half century. Cigars continued in unchallenged favour until 1920, when their consumption was equalled by cigarettes, and thereafter cigarettes reached half of total tobacco consumption by 1938 and three-fourths by 1950.

The composition of the American cigarette changed several times. Turkish cigarettes, composed wholly of tobacco imported from the orient, were favoured first, but their popularity was soon shared by Virginia types, using tobacco from the Carolinas and Virginia. (The preference for Virginia cigarettes still applied in Great Britain and the commonwealth countries in the 1950s.) With the outbreak of World War I the supply of oriental tobacco to the United States was virtually cut off, and the supply of flue-cured became inadequate. The American blend, which then appeared, contained Burley and Maryland tobaccos in addition to flue-cured and Turkish, and continued thereafter with no marked changes.

Mechanization entered the cigarette industry to a marked degree in the first half of the 20th century. Tobacco from the farm may have the midribs removed by a stemming machine, so-called green stemming. After drying, packing in hogsheads and aging up to three years, the tobacco is moistened and stemmed if this was not previously done. With certain classes of tobacco a thresher can be used for the same purpose. Blowers are used to remove dust and foreign matter.

A series of treatments alternately using moist and dry heat is used for the domestic types. Blending of all types in the proper proportions is done in revolving drums. This is followed by a storage known as bulking to ensure equal distribution of moisture. Cutting is done by machines equipped with self-sharpening rotary blades which shred the tobacco into strips only a few hundredths of an inch wide. After several days' storage, the blended mixture is made into cigarettes.

In general, four classes of tobacco are used in American blend cigarettes. Flue-cured or bright, the largest component, is grown in Virginia, North Carolina, South Carolina, Georgia and Florida. A high sugar and low nicotine content is desirable in bright tobacco.

Burley, an air-cured class, second in importance, is grown in Kentucky, Tennessee, Ohio, Indiana, Missouri, Virginia, West Virginia, North Carolina and limited areas in other states. In the cigarette, Burley counteracts the acid smoke of bright to produce a neutral reaction.

Maryland, also an air-cured type, has limited use to improve burning properties and aid aroma.

Turkish tobacco, imported into the U.S. mainly from Turkey and Greece, but also from Syria, Yugoslavia and Italy, is classed as aromatic tobacco but is also desirable for low nicotine content and mild taste. A modest quantity of aromatic tobacco is grown in the mountainous parts of North Carolina.

Standard machines produce 1,200 cigarettes a minute. Packaging machines, working twice as fast, wrap 20 cigarettes at a time in paper-backed foil, paper label and cellophane and affix the revenue stamps. Refinements in cigarette-making machinery resulted in notable increases in speed of operation. Uniformity was improved, for example, by microfeed controls, in which twin beams of nucleonic particles compare the density of the cigarette rod with a standard. The current thus generated and amplified finally regulates automatically the feed mechanism. Filter-tip attachments insert a double-length filter plug between two cigarettes, detach the tipping material and cut the assembly in two.

While packages of 20 cigarettes wrapped in paper and foil are the most common unit, sliding boxes of 20s, "flat 50s" and tins of 50 are available. Cartons of 10 packages are packed in cases of 50 cartons for shipment. All of the packing is done by automatic machines.

Dependence of the U.S. industry on France for cigarette paper was no longer necessary after development of a domestic paper industry in the early 1930s. Linen paper of the highest purity,

made from flax straw, supplies the demand for writing, printing and cigarette papers. (O. E. S.)

Production of cigarettes in the U.S. increased rapidly during and after World War I, from about 18,000,000,000 in 1915 to 124,000,000,000 in 1930. A similar rise occurred during and after World War II, from about 190,000,000,000 in 1940 to more than 400,000,000,000 in the early 1950s. Thereafter consumption tended to drop, probably as the result of medical reports linking cigarette smoking with cancer of the lungs, and also of the switch of many smokers to king-size (longer) cigarettes.

Great Britain.—In Great Britain the tobacco used in cigarettes is mostly bright flue-cured, better known as Virginia. The leaf first must be moistened to make it pliable for stemming (*i.e.*, removing the stalk or midrib). The next process is to cut the leaf into fine shreds. The cut tobacco is then conditioned, usually in large rotary drums where it is first subjected to heat to remove excess moisture and then cooled. Handmade cigarettes are relatively rare, but several "roll-your-own" machines which any person can use to make a cigarette have been developed.

In factory production cigarette-making machines produce from 1,000 to 1,600 cigarettes per minute. The cigarette paper is put up in bobbins of definite width and is fed into a narrow trough at the side of the machine. The name of the brand is imprinted on the paper at regular intervals so that it will appear on each finished cigarette. The shredded cuts of tobacco fall upon the paper, which moves into a funnel-shaped tube, passing a device which gums the edges, the paper then being automatically folded over the tobacco. The end of the cigarette moves under a knife which cuts it into sections of the desired length.

In Great Britain the type of package used is known as a slide and shell package, usually containing 10 or 20 cigarettes. The cigarettes are automatically packed by modern machinery, by which they are counted, wrapped in foil and placed in a cardboard slide. The slide is then inserted into a shell of cardboard. The machines are also capable of placing an insert in the package if necessary. The packages of many of the more popular cigarettes in Great Britain are wrapped in moistureproof cellophane in order to protect them from the varied conditions of humidity prevalent in the British Isles.

The cigarette business in Great Britain grew from year to year. In the 1950s approximately 195,000,000 lb. of tobacco were used annually in cigarettes for home consumption. Tobacco brought into Britain is taxed with heavy import duty, which is a great source of income to the British government. Virginia tobacco, grown in the United States, is predominantly used in cigarettes made in England; however, a great deal of tobacco (grown from seed imported from the United States) is shipped into England from various parts of the commonwealth and is blended in varying degrees with that imported from America. Turkish and Egyptian cigarettes were at one time popular in the British Isles, but in the 1950s accounted for only a very small business. Turkish tobacco, used widely in the United States, is imported mainly from Greece and Turkey. (X.)

Continental Europe.—Development of the cigarette industry in France, Belgium and other western European countries is quite comparable to that in the United States and Great Britain. The mechanization of the industry is aided by the use of different machines developed in several countries, notably Sweden and Switzerland. One of the cigarette factories in Switzerland uses a thermal pump, whereby water from very deep wells serves to cool the building in summer and to heat it in the winter. Average cigarette consumption in European countries usually ranges from one-third to two-thirds the U.S. usage. (O. E. S.)

CIGNANI, CARLO (1628–1719), Italian painter, was born at Bologna (May 15, 1628) and trained there chiefly under Francesco Albani. He faithfully continued the Bolognese Baroque tradition in his use of ample, generalized forms, fluently turning poses, deep colours and blended contrasts of light and shadow. In sentiment, also, his work is characteristic of this tradition. It was a tradition which derived its elements in the first place from Correggio, but Cignani was in addition influenced by Correggio directly and his masterpiece, the "Assumption of the Virgin" in the cupola of Forlì cathedral, is closely based on the former's cupola in Parma cathedral. He executed numerous altarpieces, mythological scenes and several fresco decorations (*e.g.*, in the ducal palace, Parma). There is a "Magdalene" by him in the Dulwich College picture gallery in London, Eng. Cignani died at Forlì on Sept. 6, 1719.

His son FELICE CIGNANI (1660–1724) and nephew PAOLO CIGNANI (1709–64) were also painters.

See T. Gerevich in Thieme-Becker, *Künstlerlexikon*, vi, (Leipzig, 1912), p. 576 ff. (M. W. L. K.)

CIGOLI, LODOVICO CARDI DA (1559–1613), Italian painter, architect and poet, was born at Cigoli, Tuscany, on Sept. 12, 1559; he worked both in Florence and in Rome, where he died, June 8, 1613. Trained under Alessandro Allori and Santi di Tito, he reflected the many crosscurrents in Italian art between the decline of Michelangelesque Mannerism and the beginnings of the Baroque. Thus there are few consistent characteristics in his earlier work beyond some north Italian strength of colour and lighting. He was an innovator in sentiment rather than in style and, like Federico Baroccio, foreshadowed Baroque emotions. From 1595 onward he began to reflect the new realistic tendencies. These qualities are well illustrated in his "Ecce Homo" (*c.* 1607; Pitti palace, Florence). His architecture (*e.g.*, the court of the Palazzo Nonfinito, Florence, 1604) shows the elements of Palladian classicism, which he first learned from Bernardo Buontalenti.

See G. Battelli, *Lodovico Cardi detto il Cigoli* (Florence, 1922). (M. W. L. K.)

CILIA, in biology, the threadlike processes by the vibration of which many lowly organisms move through water. They are also found on certain cells of both lower and higher organisms to create a current (*e.g.*, on the gill of oysters and the lining of the bronchioles of the lungs in man). The singular is cilium.

CILIATA, one of the divisions of Infusoria characterized by the permanent possession of cilia or organs derived from these (membranelles, etc.), and all parasitic. They are the most highly differentiated Protozoa (*q.v.*).

CILICIA, a district of Asia Minor, extending along the south coast between Pamphylia and Syria. Its northern limit was the crest of Mt. Taurus. It was divided into Cilicia Trachea and Cilicia Pedias.

Cilicia Trachea is a rugged mountain district formed by the spurs of Taurus, which often terminate in rocky headlands with small sheltered harbours—a feature which, in classical times, made the coast a resort of pirates and, in the middle ages, led to its occupation by Genoese and Venetian traders. The district is watered by the Geuk Su (Calycadnus) and is covered to a large extent by forests, which supply timber to Egypt and Syria. There were several towns but no large trade centres.

Cilicia Pedias included the rugged spurs of Taurus and a large plain of rich stoneless loam. Its eastern half is studded with isolated rocky crags, which are crowned with the ruins of ancient strongholds and broken by the low hills that border the plain of Issus. The plain is watered by the Cydnus (Tarsus Chai), the Sarus (Sihun) and the Pyramus (Jihun) and is extremely productive. Through it ran the great highway, between the east and the west, on which stood Tarsus on the Cydnus, Adana on the Sarus, and Mopsuestia (Missis) on the Pyramus. The great highway from the west, on its long rough descent from the Anatolian plateau to Tarsus, ran through a narrow pass between walls of rock called the Cilician Gate (Ghulek Boghaz). After crossing the low hills east of the Pyramus it passed through a masonry (Cilician) gate, Demir Kapu, and entered the plain of Issus. From that plain one road ran southward to Alexandretta and thence crossed Mt. Amanus by the Syrian Gate, to Antioch and Syria; and another ran northward and crossed Mt. Amanus by the Amanian Gate, to North Syria and the Euphrates. By the last pass, which was apparently unknown to Alexander, Darius crossed the mountains prior to the battle of Issus. Both passes are short and easy, and connect Cilicia Pedias with Syria rather than with Asia Minor. In Roman times Cilicia exported the goat's-hair cloth, *cilicium*, of which tents were made.

Under the Persian empire Cilicia was apparently governed by

tributary native kings, who bore a name or title graecized as Syennesis; but it was officially included in the fourth satrapy by Darius. Xenophon found a queen in power, and no opposition was offered to the march of Cyrus. Alexander found the gates open when he came down from the plateau in 333 B.C., and it may be inferred that the great pass was not under direct Persian control. After Alexander's death it fell to the Seleucids, who, however, never held effectually more than the eastern half. Cilicia Trachea became the haunt of pirates, who were subdued by Pompey. Cilicia Pedias became Roman territory in 103 B.C., and the whole was organized by Pompey (64 B.C.) into a province, of which at one time Cicero was governor. It was reorganized by Caesar (47 B.C.), and about 27 B.C. became part of the province Syria-Cilicia-Phoenice. Under Diocletian (*c.* A.D. 297), Cilicia, with the Syrian and Egyptian provinces, formed the Diocesis Orientis. In the 7th century it was invaded by the Arabs, who held the country until it was reoccupied by Nicephorus II in 965.

The Seljuk invasion of Armenia was followed by an exodus of Armenians southwards, and in 1080 there was founded in the Cilician Taurus a small principality, which gradually expanded into the kingdom of Lesser Armenia. This Christian kingdom—situated in the midst of Muslim states, hostile to the Byzantines, giving valuable support to the crusaders, and trading with the great commercial cities of Italy—had a stormy existence of about 300 years. When Levond V died (1342), John of Lusignan was crowned king as Gosdantin IV; but he alienated the Armenians by attempting to make them conform to the Roman Church, and at last the kingdom, a prey to internal dissensions, succumbed (1375) to the attacks of the Egyptians. Cilicia Trachea was occupied by the Osmanlis in the 15th century, but Cilicia Pedias was only added to the empire in 1515.

From 1833 to 1840 Cilicia formed part of the territories administered by Mohammed Ali of Cairo, who was compelled to evacuate it by the allied powers. By the treaty of Sèvres (*see* TURKEY) part of Cilicia was granted to France, but on Oct. 20, 1921, after unsuccessful conflicts with the Nationalist troops, the French withdrew all claim to this area.

CILLI, ULRICH, COUNT OF (1406–1456), son of Frederick II, count of Cilli, and Elizabeth Frangepan. About 1432 he married Catherine, daughter of George Brankovich, despot of Serbia.

His influence in the troubled affairs of Hungary and the empire, of which he was made a prince by the emperor Sigismund (1436) led to feuds with the Habsburgs, the overlords of Cilli. Finally he made an alliance with the Habsburg king Albert II, and after his death (1439) Alrich took up the cause of his widow, Elizabeth, and presided at the coronation of her infant son Ladislaus V. Posthumus (1440). A feud with the Hunyadis followed, embittered by John Hunyadi's attack on George Brankovich of Serbia (1444) on his refusal to recognize Ulrich's claim to Bosnia on the death of Stephen Tvrtko (1443). In 1446 Hunyadi, then governor of Hungary, harried the Cilli territories in Croatia-Slavonia; but his power was broken at Kosovo (1448), and Count Ulrich was able to lead a successful crusade, nominally in the Habsburg interest, into Hungary (1450). In 1452 he forced the emperor Frederick III to hand over the boy king Ladislaus V to his keeping, and became thus virtual ruler of Hungary, of which he was named lieutenant by Ladislaus in 1456. The Hunyadis now conspired to destroy him. On Nov. 8, in spite of warnings, he entered Belgrade with the king; the next day he was attacked by Laszlo Hunyadi and his friends, and put to death. With him died the male line of the counts of Cilli.

CILLI (Slovene *Celje*), a town of Slovenia, Yugoslavia, on a branch of the Zagreb-Fiume railway, lies picturesquely with remains of walls and towers on the river Sann, on an important road north to Marburg (Maribor) and south to Ljubljana. Pop. (1931) 7,602. The city was annexed by Germany in 1941. Probably a Celtic settlement, the Romans took it (15 B.C.) and Claudius made it a Roman municipium (A.D. 50), naming it Claudia Celeja. It prospered greatly, and its temple of Mars was widely famed. Its museum contains many Roman remains, and the Roman sewerage system was rediscovered in the second half of the 19th century and is now in use. It was incorporated with Aquileia under Constantine, and was destroyed by Slavs at the end of the 6th century. The counts of Cilli, at one time in authority in Croatia, at another in Bosnia, had their castle, Ober Cilli, on the Schlossberg (1,320 ft.), southeast of the town. Its ruins, the Cilli throne and the family tomb remain. Under the Cilli (1350–1455) the town prospered; on their extinction it became subject to Austria. The fine church (14th century) has a beautiful chapel and is justly renowned. The so-called German church (Romanesque) belonged to the Minorite monastery (founded 1241, closed 1808). Antimony and zinc are mined near by, and enamelled iron utensils are made. Ten miles northwest are the baths and ruined castle of Neuhaus, after 1643 called Schlangenburg.

See E. Glautschnigg, *Cilli und Umgebung; Handbuch für Fremde* (Cilli, 1887).

CIMA, GIAMBATTISTA (CIMA DA CONEGLIANO, *c.* 1459–1517), Italian painter of the Venetian school, probably a pupil of Bartolomeo Montagna, and later influenced by Giovanni Bellini. He was born at Conegliano on the southern slopes of the Alps. His earliest dated picture is the altarpiece of 1489 in the Museo Civico of Vicenza. He was then 30 years old and his style was fully developed and altered very little during the course of his long life. In 1492 he settled in Venice. In 1493 he was commissioned to paint an altarpiece for the cathedral of Conegliano which is still in its original place. Most of his important works are in Venice in the churches of S. Giovanni in Bragora, S. Maria dell'Orto, the Carmine, and in the Academy: there are also pictures by him at Bologna, Modena and Parma and in many of the great galleries in Europe.

See V. Botteon, *Ricerche intorno alla vita e alle opere di G. Cima* (1893); R. Burckhardt, *Cima da Conegliano* (1905).

CIMABUE, name of a Florentine painter Cenni di Pepo active in the 13th and the beginning of the 14th century. Some Italian painters preceded Cimabue—particularly Guido of Siena and Giunta of Pisa; but though he worked on much the same principle as they, and to a like result, he was held up to admiration as the "Father of Italian Painting" by Florentine writers, inspired by local patriotism. There is no documentary evidence that a single picture attributed to Cimabue was painted by him.

His fame rested chiefly on a colossal "Madonna and Child with Angels," the largest altarpiece produced up to that date, which was painted in tempera for the chapel of the Rucellai in St. Maria Novella, Florence; but research proved this work to be by the Siennese Duccio.

Among paintings still extant attributed to Cimabue are the following:—In the Uffizi in Florence, a "Madonna and Child," with eight angels, and some prophets in niches—better than the Rucellai picture in composition and study of nature, but more archaic in type, and the colour now spoiled (this work was painted for the Badia of St. Trinita, Florence); in the National Gallery, London, a "Madonna and Child with Angels," which came from the Ugo Baldi collection, and had probably once been in the church of St. Croce, Florence; in the Louvre, a "Madonna and Child," with twenty-six medallions in the frame, originally in the church of St. Francesco, Pisa. In the lower church of the Basilica of St. Francesco at Assisi, Cimabue, succeeding Giunta da Pisa, is said to have adorned the south transept—painting a colossal "Virgin and Child between Four Angels," above the altar of the Conception, and a large figure of St. Francis. In the upper church, north transept, he has the "Saviour Enthroned and some Angels," and, on the central ceiling of the transept, the "Four Evangelists with Angels." It is, however, impossible to say whether Cimabue was at Assisi or not.

In the closing years of his life he was appointed capomaestro of the mosaics of the cathedral of Pisa, and was afterwards

hardly a year before his death, joined with Arnolfo di Cambio as architect for the Cathedral of Florence. In Pisa he executed a Majesty in the apse—"Christ in glory between the Virgin and John the Evangelist," a mosaic, now much damaged. This was probably the last work that he produced.

He was the master of Giotto, whom (is the tradition) he found a shepherd boy of ten, in the pastures of Vespignano, drawing with a coal on a slate the figure of a lamb. Cimabue took him to Florence, and instructed him in the art; and after Cimabue's death Giotto occupied a house which had belonged to his master in the Via del Cocomero. Another painter with whom Cimabue is said to have been intimate was Gaddo Gaddi.

Giovanni Cimabue was buried in the cathedral of Florence, St. Maria del Fiore, with an epitaph written by one of the Nini:

> Credidit ut Cimabos picturae castra tenere,
> Sic tenuit vivens; nunc tenet astra poli.

Here we recognize distinctly a parallel to the first clause in the famous triplet of Dante:

> Credette Cimabue nella pintura
> Tener lo campo; ed ora ha Giotto il grido,
> Si che la fama di colui' oscura.

CIMAROSA, DOMENICO (1749–1801), Italian musical composer, was born at Aversa, in the kingdom of Naples, Dec. 17, 1749. His parents were poor, but anxious to give their son a good education, and after removing to Naples they sent him to a free school connected with one of the monasteries of that city. He obtained a free scholarship at the musical institute of Santa Maria di Loreto, where he remained for eleven years, studying chiefly the great masters of the old Italian school. Piccini, Sacchini and other musicians of repute are mentioned amongst his teachers. At the age of twenty-three Cimarosa began his career as a composer with a comic opera called *Le Stravaganze del Conte*, first performed at the Teatro dei Fiorentini at Naples in 1772. The work met with approval as did its successors *Le Pazzie di Stellidanza e di Zoroastro*, a farce full of humour and eccentricity, and another comic opera called *L'Italiana in Londra*. From 1784–87 Cimarosa lived at Florence, and wrote the following works for the theatre of that city:—*Caio Mario*; the three biblical operas, *Assalone*, *La Giuditta* and *Il Sacrificio d'Abramo*; also *Il Convito di Pietra*; and *La Ballerina amante*, a pretty comic opera first performed at Venice with enormous success.

About the year 1788 Cimarosa went to St. Petersburg (Leningrad) by invitation of the empress Catherine II. In 1792 he went to Vienna at the invitation of the emperor Leopold II. Here he produced his masterpiece, *Il Matrimonio segreto* which ranks amongst the highest achievements of light operatic music. In 1793 he returned to Naples, where *Il Matrimonio segreto* and other works were received with great applause. Amongst the works belonging to his last stay in Naples may be mentioned the charming opera *Le Astuzie femminili*, which during recent years has been adapted with great success as one of the productions of the Diaghilev Ballet.

This period of his life is said to have been embittered by the intrigues of envious and hostile persons, amongst whom figured his old rival Paisiello. During the occupation of Naples by the troops of the French Republic, Cimarosa joined the Liberal party, and on the return of the Bourbons, was, like many of his political friends, condemned to death. By the interces ion of influential admirers his sentence was commuted into banishment. But his health was broken, and after much suffering he died at Venice Jan. 11, 1801, of inflammation of the intestines. The nature of his disease led to the rumour of his having been poisoned by his enemies, which, however, a formal inquest proved to be unfounded.

CIMBALO: *see* Cembalo.

CIMBRI, a Teutonic tribe which in 113 B.C. defeated the consul Gnaeus Papirius Carbo near Noreia. They had been wandering along the Danube for some years, warring with the Celtic tribes on either bank. After the victory of 113 B.C. they passed westwards over the Rhine, threatening the territory of the Allobroges. Their request for land was not granted, and in 109 B.C. they defeated the consul Marcus Junius Silanus in southern Gaul, but did not at once follow up the victory. In 105 B.C. they returned to the attack under their king, Boiorix, and annihilated the Roman armies at Arausio (Orange). Again the victorious Cimbri turned away from Italy, and, after attempting to reduce the Arverni (*q.v.*), moved into Spain, where they failed to overcome the desperate resistance of the Celtiberian tribes. In 103 B.C. they marched back through Gaul, which they overran as far as the Seine, where the Belgae made a stout resistance. Near Rouen the Cimbri were reinforced by the Teutoni and two cantons of the Helvetii. They marched southwards by two routes, the Cimbri moving on the left towards the passes of the eastern Alps, while the newly arrived Teutoni and their allies made for the western gates of Italy. In 102 B.C. the Teutoni and Ambrones were totally defeated at Aquae Sextiae by Marius, while the Cimbri succeeded in passing the Alps and driving Q. Lutatius Catulus across the Adige and Po. In 101 B.C. Marius overthrew them on the Raudine Plain near Vercellae. Their king, Boiorix, was killed, and the whole army destroyed. The Cimbri were the first in the long line of the Teutonic invaders of Italy.

The original home of the Cimbri has been much disputed. From information gained from the *Monumentum Ancyranum* and the map of Ptolemy, it may reasonably be conjectured that they came from the peninsula of Jutland, where their name may be preserved in Himmerland (Aalborg). Strabo and other early writers related a number of curious facts concerning the customs of the Cimbri, which are of great interest as the earliest records of the manner of life of the Teutonic nations.

IV. xiii. and xiv., all in Bibliotheca Script. Graec. et Roman. Teubneriana, Leipzig; Plutarch, "Marius," in vol. ix. of Plutarch's *Lives*, with Eng. trans., B. Perrin (1920); Strabo, *Geography*, Bk. VII. i. and ii., with Eng. trans., H. L. Jones (1917–27), both in the Loeb Classical Library; Ptolemy, *Geography*, Bk. II. xi., ed. O. Cuntz (1923). For *Monumentum Ancyranum* *see* Ancyra.

CIMICIFUGA, a genus of herbs of the family Ranunculaceae, comprising 12 species widely distributed in the north temperate zone; the bugbanes. The root of *C. foetida* was used as a preventive against vermin and that of the North American black snake-root (*C. racemosa*) as an emetic.

CIMINIA, VIA, an ancient road of Italy, which diverged from the Via Cassia at Sutrium, and led along the east side of the Lacus Ciminius (Macaulay's "Ciminian mere," mod. Lago di Vico, an extinct crater basin) out of which it climbed on the north to 2,785 feet. Thence it descended and rejoined the Via Cassia at Aquae Passeris, a few miles north of Viterbo. The Ciminian hills are still wooded, and of great beauty. Caprarola on the east slopes of the crater, contains a very fine palace built for Alessandro Farnese in 1547–59 by Vignola, with the interior decorated by the Zuccari brothers; other villages in the district (notably Soriano with the Palazzo Chigi, which also has a fine castle of 1278), also contain good specimens of his architecture; while S. Martino al Cimino has a fine French Gothic 13th century church.

See S. Bargellini, *I Monti del Cimino* (Bergamo, *Arti Grafiche*, 1914, well illustrated).

CIMMERII, an ancient people of the far north or west of Europe, first spoken of by Homer (*Odyssey*, xi. 12–19), who describes them as living in perpetual darkness. Herodotus (iv. 11–13), in his account of Scythia, regards them as the early inhabitants of South Russia (after whom the Bosporus Cimmerius [*q.v.*] and other places were named), driven by the Scyths along by the Caucasus into Asia Minor, where they maintained themselves for a century. But it is quite possible that some Cimmerii made their raids across the Hellespont, having been cut off by the Scyths as the Alani (*q.v.*) were by the Huns. Certain it is that in the middle of the 7th century B.C., Asia Minor was ravaged by northern nomads (Herod. iv. 12), one

body of whom is called in Assyrian sources *Gimirrai* and is represented as coming through the Caucasus. They were probably Iranian speakers, to judge by the few proper names preserved. The name has also been identified with the biblical Gomer, son of Japheth (Gen. x. 2, 3). Later writers identified them with the Cimbri of Jutland, who were probably Teutonized Celts, but this is a mere guess due to the similarity of name.

For the Cimmerian invasions described by Herodotus, *see* SCYTHIA; LYDIA; GYGES.

CIMON (*c.* 507–449 B.C.), Athenian statesman and general, was the son of Miltiades (*q.v.*) and Hegesipyle, daughter of the Thracian prince Olorus. Cimon's first task in life was to pay the fine (about £12,000) which had been imposed on Miltiades after the Parian expedition. After winning a high reputation in the second Persian invasion, he served under Aristeides with the Athenian fleet and later (477, see *Camb. Anc. Hist.*, vol. v. App. B) became sole commander. His first success was the expulsion of Pausanias from Byzantium. Having captured Eion (at the mouth of the Strymon), he expelled the Persian garrisons from the entire seaboard of Thrace with the exception of Doriscus, and, having captured Scyros (470), confirmed his popularity by transferring thence to Athens the supposed bones of Theseus. In 466 Cimon proceeded to liberate the Greek cities of Lycia and Pamphylia, and at the mouth of the Eurymedon he defeated the Persians decisively by land and sea.

The Persian danger was now over, and the immediate purpose of the Delian League was achieved. Already, however, Athens had introduced the policy of coercion which was to transform the league into an empire, a policy which, after the ostracism of Themistocles and the death of Aristides, must be attributed to Cimon, whose fundamental idea was the union of the Greeks against all outsiders (*see* DELIAN LEAGUE). Carystus was compelled to join the league; Naxos (*c.* 469) and Thasos (465–463), which had revolted, were compelled to accept the position of tributary allies. In 464 Sparta was in difficulties, owing to the revolt of her Helots. Cimon persuaded the Athenians to send aid, on the ground that Athens could not "stand without her yokefellow" and leave "Hellas lame." The expedition was a failure, and Cimon was attacked by the democrats led by Ephialtes. The history of this struggle is not clear. The ordinary account is that Ephialtes during Cimon's absence in Messenia overthrew the Areopagus (*q.v.*) and then obtained the ostracism of Cimon, who tried to reverse his policy. It may be pointed out that when the Messenian expedition started, Cimon had twice within the preceding year triumphed over the opposition of Ephialtes, and that presumably the Cimonian party was predominant until after the expedition proved a failure. It is therefore unlikely that, immediately after Cimon's triumph in obtaining permission to go to Messenia, Ephialtes was able to attack the Areopagus with success. The chronology would thus be: ostracism of Cimon, spring, 461; fall of the Areopagus, summer, 461.

A more difficult question is involved in the date of Cimon's return from ostracism. The ordinary account says that he was recalled after Tanagra (457) to negotiate the Five Years' Truce (451 or 450). Some writers, maintaining that Cimon did return soon after 457, say that the truce which he arranged was really the four months' truce recorded by Diodorus (only). To this there are two main objections: (1) if Cimon returned in 457, why does the evidence of antiquity connect his return specifically with the truce of 451? and (2) why does he after 457 disappear for six years and return again to negotiate the Five Years' Truce and to command the expedition to Cyprus? It seems much more likely that he returned in 451, at the very time when Athens returned to his old policy of friendship with Sparta and war against Persia (*i.e.*, the Cyprus expedition).

Cimon died in Cyprus (449), and was buried in Athens. Later Attic orators speak of a "Peace" between Athens and Persia, which is sometimes connected with the name of Cimon and sometimes with that of Callias. If any such peace was concluded, it cannot have been soon after the battle of the Eurymedon as Plutarch assumes. It can have been only after the evacuation of Cyprus (*i.e.*, *c.* 448). There are weighty reasons which render it improbable that any formal peace can have been concluded at that period between Athens and Persia (see further Ed. Meyer's *Forschungen*, ii.).

Cimon's services in consolidating the empire rank with those of Themistocles and Aristeides. He is described as genial, brave and generous. The one great principle for which he is memorable is that of the balance of power between Athens and Sparta, as respectively the naval and military leaders of a united Hellas. It has been the custom to regard Cimon as a man of little culture. The truth is that, as in politics, so in education and attitude of mind, he represented the ideals of an age which, in the new atmosphere of democratic Athens, seemed to savour of rusticity and lack of education.

BIBLIOGRAPHY.—The lives of Cimon by Plutarch and Cornelius Nepos are uncritical; the conclusions above expressed are derived from a comparison of Plutarch, *Cimon*, 17, *Pericles*, 10; Theopompus, frag. 92; Andocides, *de Pace*, §§ 3, 4; Diodorus xi. 86 (the four months' truce). *See* histories of Greece (*e.g.*, Grote, ed. 1907), *Cambridge Ancient History*, vol. v., c. ii. and iii.; also PERICLES; DELIAN LEAGUE, with works quoted.

CIMON OF CLEONAE, an early Greek painter, who is said to have introduced great improvements in drawing. He represented "figures out of the straight, and ways of representing faces looking back, up or down; he also made the joints of the body clear, emphasized veins, worked out folds in garments" (Pliny).

CINCH, a Mexican saddle girth; figuratively, a secure hold.

CINCHONA, an important genus of shrubs and trees, family Rubiaceae, closely related to coffee and ipecac. The 38 species are found on the warm, moist Amazonian slopes of the Andes from Colombia to Bolivia at elevations of 5,000–8,500 feet, a few above and some below this. They have opposite leaves and pink or whitish, sometimes fragrant, usually cymose, flowers in lilac-like clusters. A few of the species are of world importance because their bark is the only source of quinine (*q.v.*) the specific for malaria, and widely used in the treatment of influenza, the common cold and some other diseases.

Some species also yield totaquina. The medicinal value of cinchona bark was unknown to the Incas, and it is not mentioned in Gracilasso de la Vega's *Royal Commentaries on the Incas* or in Pedro de Cieza de Leon's *Chronicles of Peru*, published in 1553.

The oft repeated tale of the first use and introduction of cinchona bark to Europe by the Countess of Chinchon in 1638 was completely disproved by A. W. Haggis in 1941, as the wife of the Viceroy of Peru never had malaria, died at Cartagena on her way to Spain and hence could not have carried cinchona bark to Europe. Who took it there, and when, will probably never be settled. It was known to the Jesuits at Lima about 1630, hence its common appellation of Jesuits' bark and Peruvian bark. The first mention in European medical literature was by Herman van der Heyden, in his *Discours et advis sur les flus de ventre douloureux*, Antwerp, 1643.

For the next two hundred years cinchona bark was ruthlessly exploited especially after the isolation of its chief constituent by Pelletier and Caventou in 1820 had demonstrated that the quinine content dictated its price. Bark depletion seemed so inevitable that Hasskarl for the Dutch and Sir Clements Markham for the English were sent to South America between 1859–63 in an attempt to introduce cinchona culture to Java and India. Both expeditions failed because they did not secure varieties of high quinine content. In December 1865 there arrived in Java a pound of seed from Charles Ledger of Puño, Peru, collected on the banks of the upper Marmoré River in Bolivia.

The progeny of these, and subsequent skilful cultivation by the Dutch, resulted in Java becoming the world source of cinchona bark and hence of quinine. Part of the Ledger seed was planted by the British at their government cinchona station in Madras, where it failed. That failure was disastrous, for India has the highest incidence of malaria in the world and the inferior Indian varieties have never yielded enough quinine. Private planters have abandoned its culture for more profitable crops; and government plantations are supplemented by importation from Java. Dutch bark production yielded 1017 tons of quinine in 1941, all derived from *Cinchona ledgeriana*. The only other spe-

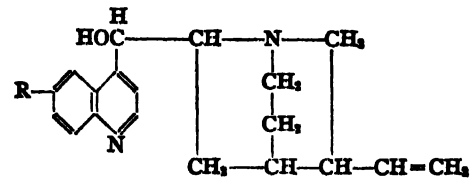
cies grown commercially in Java is *C. succirubra*, which yields quinidine, cinchonine and cinchonidine. (N. Tr.)

CINCHONA BARK, ALKALOIDS OF. About 30 distinct alkaloids have been isolated from cinchona bark, of which quinine is by far the most important, followed by quinidine, cinchonidine and cinchonine. Because of the therapeutical importance of cinchona bark and its four principal alkaloids most of the national pharmacopoeias prescribe methods of estimating these constituents in the bark and lay down standards both for the bark and for quinine. Thus, the British Pharmacopoeia requires that red cinchona bark should yield from 5% to 6% of alkaloids, of which not less than half must consist of quinine and cinchonidine, and for quinine sulphate a test is prescribed which excludes all but a minimum quantity of cinchona alkaloids, other than quinine. (For further information *see* ALKALOIDS.)

Quinine, $C_{20}H_{24}O_2N_2$.—This alkaloid is rarely seen or used, except in the form of its salts with acids. Though it contains two atoms of nitrogen it behaves as a monoacidic base yielding a sulphate of the formula $(C_{20}H_{24}O_2N_2)_2$, H_2SO_4, $7H_2O$, popularly known as quinine. It crystallizes in bulky masses of colourless, glistening needles, which become dull on exposure to air because of the loss of five of their molecules of water of crystallization, so that the thoroughly stable, air-dry salt has the composition $(C_{20}H_{24}O_2N_2)_2$, H_2SO_4, $2H_2O$. It is sparingly soluble in water, more so in alcohol and still more in a mixture of alcohol and chloroform. The solutions are laevorotatory and those in water, especially when acidified, are strongly fluorescent. Two other sulphates, $C_{20}H_{24}O_2N_2$, H_2SO_4, $7H_2O$ (so-called bisulphate) and $C_{20}H_{24}O_2N_2$, $2H_2SO_4$, $7H_2O$ (so-called tetra-sulphate), are known and are used when more soluble salts are required. Quinine hydrochloride, $C_{20}H_{24}O_2N_2$, HCl, $2H_2O$, which closely resembles the ordinary sulphate in appearance but has the advantage of being a little more soluble in water, is also in use. In addition, a great variety of special salts have been made in attempts to combine the therapeutic advantages of quinine with those of medicinally valuable acids; *e.g.*, quinine salicylate, acetylsalicylate, valerianate, cacodylate, etc.

On reduction quinine furnishes hydroquinine, which also occurs in cinchona bark and is the raw material for the production of a series of drugs in which the side chains of quinine are modified to enhance its therapeutic properties in certain directions. The best known of these modified cinchona alkaloids is eucupin.

Quinidine, $C_{20}H_{24}O_2N_2$ (also called conquinine).—This alkaloid, which is a dextrorotatory isomeride of quinine, crystallizes from alcohol in colourless prisms and melts when dry at 171.5° C. It forms two series of salts analogous with those of quinine.



Cinchonine $C_{19}H_{22}ON_2$.—This alkaloid crystallizes from alcohol in rhombic prisms and melts at 264° C. It is dextrorotatory in solution and like the other cinchona alkaloids yields two series of salts with acids.

Cinchonidine, $C_{19}H_{22}ON_2$.—This laevorotatory isomeride of cinchonine (*see* above), is one of the chief constituents of the mixture of alkaloids present in red cinchona bark, the variety now generally produced for making galenical preparations of cinchona. It crystallizes from alcohol in large colourless prisms, melting at 207° C., and corresponds with quinine in being laevorotatory in solution, but is unlike it in showing no fluorescence in dilute sulphuric acid. It forms two series of salts, analogous with those of quinine described above.

These four cinchona alkaloids have been the subject of investigations designed to determine their constitution and permit of their synthesis, almost continuously since they were discovered in 1820.

The reactions of the four alkaloids can all be accounted for on the basis of the structural formula below, which was developed by P. Rabe (1909), and which represents them as containing a quinoline (left) and a quinuclidine (right) nucleus, joined by a secondary alcohol group.

The difference between the two pairs (1) quinine and quinidine and (2) cinchonine and cinchonidine, is that in the first pair, R on the quinoline nucleus is a methoxyl (CH_3O) group, while in the second pair, R is hydrogen. Within each pair, the two alkaloids differ in the spatial arrangement of the H and OH of the secondary

Cinchona Alkaloids, Type Formula

alcohol group (*see* STEREOCHEMISTRY). Confirmation of the structures assigned to the cinchona alkaloids involved great difficulty. It was attained in 1931 with the synthesis of hydroquinine and hydroquinidine by Rabe, and with that of quinine itself by R. B. Woodward and W. E. Doering in 1944.

Further it should be noted that there is now some reason to believe that the protozooicidal action of these alkaloids, to which is due their value in malaria, is associated mainly with the quinoline nucleus, while their action on the heart, which has led to the use of quinidine in cardiac therapeutics, is due to the quinuclidine nucleus, since sparteine, which also contains this nucleus, is stated to exert a similar action. (*See* also QUININE.) (T. A. H.; L. F. St.)

CINCINNATI, a city and the county seat of Hamilton county, Ohio, U.S., 39° 8′ N., 84° 30′ W., on the north bank of the Ohio river opposite the mouth of the Licking, about 116 mi. S.W. of Columbus, about 281 mi. by rail S.E. of Chicago and about 755 mi. (by rail) W.S.W. of New York city. Through the city flows Mill creek; to the east the Little Miami and to the west the Great Miami empty into the Ohio. Population (1950) 503,998. Previous census reports were (1810) 2,540; (1830) 24,831; (1850) 115,435; (1870) 216,239; (1890) 296,908; (1910) 363,591; (1930) 451,160; (1940) 455,610. The resident birth rate in 1949 was 24.6 per thousand and the death rate 12.7 per thousand.

Cincinnati is on two plateaus—one about 60 ft., the other 100–150 ft., above low water—and on hills (400–460 ft.) which enclose these terraces on three sides. The city datum is 546.9 ft. above sea level, zero river gauge 430.06 ft., low-water mark 431.96 ft. The low-water record is 1.9 ft. (Sept. 1881) and high-water 79.9 ft. (Jan. 26, 1937). About half the river plain (average above sea level 550 ft.) lies south of the Ohio in Kentucky, where Covington, Newport and other suburbs are located. Cincinnati has a river frontage of about 27 mi., extends back about 6 mi. in the valley of Mill creek and occupies a total area of 75 sq.mi. It was connected in 1867 with Covington by a suspension bridge (1,057 ft. between towers; total 2,252 ft.). Two bridges lead to Newport; one to Ludlow; and one to West Covington.

On the terraces the streets generally intersect at right angles, but on the hills irregularly. The wholesale district is for the most part, in the "bottoms." Manufacturing is scattered widely, with the largest concentration also in the "bottoms" area of the city. Other important areas are lower Mill creek valley, St. Bernard-Ivorydale, North Norwood and Oakley.

Many of the finer residences are on the picturesque enclosing hills; but there is a tendency toward more remote and larger estates. Among Ohio suburbs are Norwood (pop. 35,001); Cheviot (pop. 9,944); Reading (pop. 7,836); St. Bernard (pop. 7,066); Wyoming (pop. 5,582); Lincoln Heights (pop. 5,531).

Average summer temperature is 75° F.; autumn 57°; winter 34°; spring 54°; yearly average 55°. Mean annual precipitation is 40.63 in. Average wind velocity is 7.1 mi. per hour.

Buildings.—The U.S. government building, Union terminal, Hamilton county courthouse and the city hall are monumental structures. Notable among the hundreds of churches are St. Peter in Chains (1844), used as the cathedral until superseded by St. Monica in 1938; St. Francis de Sales; the First (1835) and Second Presbyterian (1872); Christ Church (1835); and the Jewish temples. A distinctive feature of downtown Cincinnati is the number of church spires and steeples. It is the seat of a Roman Catholic archbishopric and a Protestant Episcopal bishopric.

Tallest buildings are the Carew Tower (574 ft.) and Union Central building (495 ft.). The Terrace Plaza, completed in 1948, is a combination department store and hotel. Other notable build-

ings are those of the telephone company, gas and electric company, *Times-Star, Enquirer* and the Masonic temple.

The completion in 1950 of the home of Clarence A. Mills, medical climatologist, was heralded as the most revolutionary house of the preceding 50 years, being heated and cooled by reflective radiant conditioning.

Parks.—Cincinnati parks are under a park board (three members) appointed by the mayor, created in 1908 when the city owned 485 ac. of parks. In 1950 the total area was 3,655 ac. In general the parks are located on hilltops, affording a view of the downtown area, the Ohio river and the neighbouring hills, but many small parks such as Lytle (1 ac.) and Washington (5 ac.) are located downtown.

Eden park, closest of the large parks, has 184 ac. It was originally a vineyard belonging to Nicholas Longworth, great-grandfather of the speaker of the house of the same name, and called the Garden of Eden. Located there are the Cincinnati Art museum and Art academy and the Irwin M. Krohn conservatory, with displays of tropical and greenhouse plants and special flower exhibits, particularly at Thanksgiving and Easter. Mount Airy forest (1,364 ac.) was the first municipal forest in the United States. More than 1,125,000 trees had been planted by mid-20th century and 12 mi. of pedestrian and 14 mi. of equestrian trails laid out.

Burnet Woods (109 ac.) adjoining the campus of the University of Cincinnati, has many fine plant and tree specimens and the Trailside museum, headquarters for park nature activities. Alms park (85 ac.) overlooks the Ohio river with an especially fine view. Ault park (237 ac.), another hilltop park, features ornamental trees, shrubs and flowers. The Cincinnati Zoological Garden was founded in 1875 and acquired by the city in 1933. Its 57 ac. house birds, beasts and reptiles in natural settings. During the summer season wild animals are kept in barless grottoes surrounded by water-filled moats. An amphitheatre with about 1,000 seats was completed in 1951.

Education.—In 1950 there were 63 elementary, 9 junior high, 5 senior high, 4 vocational and 10 special schools in the public school system, with total enrolment of 59,091. The system of publicly supported education is completed by the University of Cincinnati, the first municipal university chartered in Ohio under the earliest municipal university statute in the United States (1870). The university was formed by uniting the Cincinnati Astronomical society (1842) and McMicken university (1859), later joined by Cincinnati college (1819) and the Medical College of Ohio (1819). The campus adjoins Burnet Woods. Included are a graduate school, teachers' college, colleges of engineering, business administration, medicine, law, applied arts, nursing and health, home economics, and an evening college. The "co-op" system of combining college instruction with practical paid training in industry under actual commercial conditions was originated at the university by Dean Herman Schneider. The college of law developed from the law school of Cincinnati college, and the college of medicine from the Medical College of Ohio (1820), each the first in the new west. University enrolment in 1950 was 15,170, 7,274 in day classes and 7,896 in the evening college. The faculty exceeded 1,200. The University observatory dates from 1843. In 1868 its director, Cleveland Abbe, inaugurated a system of daily weather reports from which the U.S. weather bureau developed. Newer buildings are McMicken hall, the Student Union building and the University library. Support is derived from endowments, fees and municipal taxes.

There were 61 elementary Catholic parochial schools in 1950, with enrolment of 17,497, and 15 diocesan high schools with enrolment of 5,993; also Concordia Lutheran parochial school. The Athenaeum of Ohio was incorporated in 1928 to control the Roman Catholic institutions of higher learning: Mount St. Mary of the West seminary, St. Gregory seminary and teachers' college. The Institutum Divi Thomae was established in 1935 as the department of scientific research of the Athenaeum.

Xavier university, Roman Catholic, founded by Bishop Fenwick in 1831, is located on Victory parkway. Enrolment in 1950 was 2,851—1,415 day, 163 graduate, 1,147 evening and 126 Milford preparatory seminary. The faculty numbered 150.

Hebrew Union college (1875) is the oldest rabbinical school in the United States. In Jan. 1950 it merged with the Jewish Institute of Religion of New York city (1922). Its library contains the largest collection in the U.S. of the minute books of U.S. congregations and an important collection of Judaica. The Ohio Mechanics' institute (1828) prepares skilled workmen and industrial executives. It offers instruction in a wide variety of trades—mechanical, chemical and electrical—in day, evening and summer classes. Salmon P. Chase college (Cincinnati Y.M.C.A.) includes a college of law (1893) and an evening college of commerce (1920) and opened also (1946) a day school. There are also the College of Pharmacy and Our Lady of Cincinnati college (Roman Catholic).

The Public library, established in 1867, includes the main library, 40 branches, 3 bookmobiles and 296 smaller agencies serving city and county. It had 156,797 registered cardholders and 1,584,667 vol. in 1950. Among special libraries are the County Law library and the Lloyd library, outstanding in pharmacy, botany, chemistry and natural sciences. The library of the Historical and Philosophical Society of Ohio, on the University of Cincinnati campus, contains an important collection of books, newspapers, maps and manuscripts.

Hospitals and Charity.—The General hospital (850 beds), completed in 1915, occupies a plot of 27 ac. Built on the pavilion plan, it consists of 24 interconnected buildings, including the Hospital for Contagious Diseases. Near by are the University of Cincinnati college of medicine, the Children's (1883) and the Christian R. Holmes (1929) hospitals. Private general hospitals include Bethesda, Christ, Deaconess, Jewish, Good Samaritan, Our Lady of Mercy and St. Mary hospitals, St. Francis and St. George. Special hospitals are Chronic Disease (county), Longview (state) and Cincinnati sanitarium for the mentally ill, and Dunham (county) for tuberculosis patients. A Veterans' administration hospital was under construction (1950).

There are numerous charitable institutions. The Community Chest, organized in 1915, has been a major factor in their support. In 1950 more than $2,657,000 was raised for allocation among 82 health and welfare agencies.

Water Supply.—The municipally owned water works were placed in service in 1907. Water is taken from the Ohio river on the Kentucky side several miles above the discharge from the city sewers. It comes through a seven-foot gravity tunnel under the river to the Ohio side, the water being thence elevated by four steam-driven pumping engines (daily capacity 30,000,000 gal.) and four electrically driven pumps (daily capacity 15,000,000 gal.) into settling basins (capacity 400,000,000 gal.). From this point the water flows by gravity through chemical house and filter house (rapid sand filters capacity 200,000,000 gal.), thence through two tunnels, one seven feet in diameter and four miles long leading to a pumping station with 103,000,000 gal. per day capacity, and the other eight feet in diameter and two and one-half miles long to a station with 100,000,000 gal. capacity.

Because of the diversified topography there are three pumping districts. In the business district, Eden park reservoir stores 96,000,000 gal. (three average days' supply); in the eastern hills, the Mt. Auburn and Eastern Hills tanks and reservoirs contain 42,000,000 gal. (two days' supply), and in the western hills two groups of tanks contain 12,300,000 gal. (two days' supply). The daily average consumption at mid-20th century was 82,000,000 gal. The system is entirely self-supporting.

Transportation.—Cincinnati at mid-century had about 845 mi. of paved streets and sewers. The city is served to a great extent by two transit systems—the Cincinnati Street Railway company, operating over a major portion of the area north of the Ohio river on a service at cost system; and the Cincinnati, Newport and Covington Railway company, connecting Cincinnati with near-by Kentucky cities. These systems are supplemented by several suburban bus lines.

Eight railroads operating 12 trunk lines radiate from the city. The single Union terminal, unusually fine and commodious, accommodates 17,000 people and more than 100 trains daily. The Cincinnati Southern railway (336 mi.) from Cincinnati to Chattanooga, Tenn., is municipally owned. It was leased to the Cincin-

nati, New Orleans and Texas Pacific Railway company until 2026 at a rental of $1,350,000 per year plus a percentage of net profit. In 1950 there were seven certificated water freight carriers and two passenger excursion steamboats. Six scheduled airlines operated from the Lunken Municipal airport and the Greater Cincinnati airport, Boone county, Ky.

Administration.—A home-rule charter was adopted in 1917 and amended in 1924 to establish a city-manager form of government. A revised charter was adopted in 1926, effective from Jan. 1927. There is a council of nine, nominated by petition and elected at large for two years; the council elects one of its members as presiding officer, who becomes the mayor. The mayor presides at meetings of the council. He appoints the city auditor and members of independent commissions and boards.

The city manager is chosen by the council for an indefinite term. He makes most of the executive and administrative appointments, prepares the budget, supervises the various public services and keeps the council informed of the city's condition.

The bonded debt in 1950 was $77,117,330.81; the net amount not self-supporting was $41,766,064.10. The tax rate for 1950 was $26.10, of which $11.72 was for the city and the remainder for state, county and educational purposes. Between 1940 and 1950 the citizens of Cincinnati voted $81,325,000 in bonds for public improvements in city and county.

Industries.—Cincinnati has a diversity of industry. As listed by the U.S. census of manufactures of 1947, the Cincinnati metropolitan area had 1,700 establishments, employing 135,774 people, whose total salaries and wages amounted to $382,935,000; the value added by manufacture was $777,201,000. In the production of soap, machine tools, playing cards and electrotypes, Cincinnati led the world. There were 43 men's and boys' suits and coats establishments with a value added by manufacture of $23,906,000; 22 machine-tool firms with a value added of $46,542,000, paper and allied products, 44 firms with a value added by manufacture of $38,236,000; wholesale meat packing, 26 firms and an added value of $11,236,000; printing and publishing, 271 firms with an added value of manufacture of $62,637,000. Cincinnati is also a leader in the production of office furniture, laundry machinery, printing inks, books, shoes, sheet metal products, engineering appliances, coffins, plastics, radio and television sets, sporting goods, malt liquors, chemicals and still-mill products.

A great bituminous coal centre, Cincinnati at mid-century was handling more than 520,000 cars annually with a tonnage of 29,120,000 and more than 4,000,000 additional tons on the river. An indication of the city's business stability was the fact that 77 business establishments had enjoyed a continuous existence of more than 100 years. Bank clearings for 1949 amounted to $8,516,752,660, and bank debits $10,187,117,000.

Art, Music and Literature.—Musical development began in 1810–20; by 1825 musical academies, choral societies performing the works of George Frederick Handel and Franz Joseph Haydn, and musical publications were quite numerous. Joseph Tosso, famed for performances of the "Arkansas Traveler," went to Cincinnati in 1820 and remained for 60 years. The drama was popular. It was, however, the large influx of Germans in the 1840s and later that promoted music most. Stephen Foster spent several years there. A sängerfest was held in 1849 and again in 1870, when a hall was built for it. Under Theodore Thomas (1835–1905) the Cincinnati Musical Festival association was incorporated, and its biennial May festivals began in 1873. In 1875–78 was built the Springer Music hall, and the Cincinnati College of Music was endowed in 1878. Theodore Thomas was its director in 1878–81; a statue of him by Clement J. Barnhorn stands in Music hall. Until his death Thomas was director of the May festivals. The sängerfest met in Cincinnati for the third time in 1879 and its jubilee was held there in 1899. Choral societies have been important in musical life, as has the Cincinnati Conservatory of Music (1867), the Cincinnati Symphony orchestra (1893) and the Cincinnati Summer opera (1920) with first-rate performances given at the Cincinnati Zoo.

A number of early U.S. artists, such as Frederick Eckstein and Hiram Powers, lived in Cincinnati, where German influence greatly promoted art. In 1877 the Women's Art Museum association brought about the building of the Art museum. A school of design (1869) was a part of the university until 1884, when it was transferred to the museum. An art academy was erected in 1887 near the Art museum. Frank Duveneck was for some time director of the academy, and the Duveneck room in the museum contains a great many of his works. Henry Farny was another artist of repute. The Taft House museum (1932) is the gift of their home and art collection by Mr. and Mrs. Charles P. Taft. Built in 1819–20, it is one of the finest examples of the Early Federal style of architecture. The Rookwood pottery was the first (1880) in the United States to devote exclusive attention to artware. The earlier wares were yellow, brown and red, then came deep greens and blues, followed by mat-glazes and by "vellum" ware (1904), a lustrous pottery resembling old parchment, with decoration painted or modelled or both. Lithographing became important in Cincinnati in the first half of the 19th century.

Principal daily newspapers in 1950 were the *Post*, founded 1881 as the *Penny Paper*; the *Times-Star*, which traced its descent from the *Cincinnati Times* (1840); and the *Enquirer* (1841). There was also the *Union*, a Negro weekly (1907), the Catholic *Telegraph-Register* (1821) and the *American Israelite* (1854). The *Freie Presse*, a weekly, was the only German language paper. The city's Literary club celebrated its centennial in 1949.

In the centre of the city is the Tyler Davidson bronze fountain (1871) on Fountain square. It was designed by August von Kreling and comprises 15 bronze figures cast at the royal bronze foundry in Munich, Ger.; the base is of porphyry. Other notable monuments are those to James A. Garfield by Charles H. Niehaus, the William Henry Harrison by L. T. Rebisso, George Grey Barnard's Lincoln, the Galbraith memorial, the Ft. Washington monument, McCook and Hecker busts and a monument to Ohio volunteers killed in the Civil War.

History.—The site of Cincinnati was a centre of the mound-builder civilization. Forts, burial mounds and other remains of their activities have been found there. René Robert Cavalier, sieur de la Salle is said to have been the first white man to pass this point on his way down the river in 1669. The Indians in the Ohio valley belonged to the Algonquin family. From the Wabash to the two Miamis were tribes of the Miamis.

On a journey to the Miami country in 1787, John Cleves Symmes (1742–1814), New Jersey congressman, was so attracted by its fertile valleys and clear streams that he purchased the land between the Miami rivers. Columbia, the first settlement, was founded near the mouth of the Little Miami in 1788. It was followed, six weeks later, by a town opposite the mouth of the Licking river, and in Feb. 1789 by a third settlement at North Bend. The second of these was destined to grow and become a large city. Named Losantiville by John Filson, schoolmaster and surveyor, he intended it to mean "the town opposite the mouth of the [L]icking." Gen. Arthur St. Clair or Israel Ludlow, a surveyor, changed the name of Losantiville to Cincinnati in 1790, in honour of the Society of the Cincinnati (*q.v.*). St. Clair created Hamilton county with Cincinnati as county seat. With the coming of soldiers to Fort Washington, it became the centre of activities against the Indians. Gen. Anthony Wayne's victory at Fallen Timbers (1794) ended Indian warfare and opened the country to settlement. In 1802, with 700 inhabitants, the military post was incorporated as a town and in 1819 became a city (pop. 10,283).

In 1811 the "New Orleans," first steamboat on western waters, passed Cincinnati and opened a new era. By 1826 steamboat building had become an important industry and the town was a busy port. During the 1830s and 1840s Ohio's canals further stimulated Cincinnati boatbuilding and by serving as feeders greatly swelled trade on the Ohio river. River commerce was at its height in 1852, with 8,000 steamboat arrivals.

In 1842 Cincinnati was one of the few U.S. cities liked by Charles Dickens, but by the late 1840s another British visitor, a Mrs. Houston, called it "a city of pigs, a monster piggery." Small wonder that it received the nickname of "Porkopolis"; between 1842 and 1852, 27% of the hogs packed in the United States were

packed there. Although there were still 33 large-scale pork-packing houses in Cincinnati in 1859, the grain fields were moving west and the meat-packing industry went with them to Chicago and St. Louis, Mo. Cincinnati's northern neighbours surpassed it in population and industry and it lost its position as third largest city in the United States.

In the 1850s the Germans began coming in great numbers, and by the 1870s they had made the city almost bilingual. Until World War I, German was taught in all public and parochial schools. By the 1890s the section north of the canal was known as the "Over-the-Rhine" region.

Although Cincinnati had close commercial and cultural ties with the south, it became an important station on the "Underground railroad" prior to the Civil War, and sided with the North when war came. In 1862 there was a threatened invasion by a Confederate force under Gen. Kirby Smith and for a time the city was under martial law, but the invasion did not take place.

Residential development began to climb up to the hilltops. In the 1870s five inclined-plane railways were built, all later abandoned. The rugged terrain encouraged the growth of independent neighbourhoods, many of them retaining their identities. In 1925 Cincinnati adopted a city master plan. Realizing that this plan needed revamping, city officials in 1944 authorized the City Planning commission to bring it up to date. The Metropolitan Master plan was completed in 1948 at a cost of more than $250,000. It called for the redevelopment of the downtown river front, a system of motor expressways and off-street parking facilities, the reclamation of blighted areas and the protection of residential neighbourhoods.

(E. L. Hs.)

CINCINNATUS, LUCIUS QUINTIUS (b. *c.* 519 B.C.), one of the heroes of early Rome. He worked his own small farm. A persistent opponent of the plebeians, he resisted the proposal of Terentilius Arsa to draw up a code of written laws applicable equally to patricians and plebeians. Twice he was called to the dictatorship of Rome (458 and 439). In 458 he defeated the Aequians in a single day, and after entering Rome in triumph with large spoils returned to his farm. The story of his success, related five times under five different years, possibly rests on an historical basis, but the account given in Livy is incredible.

See Livy iii. 26–29; Dion. Halic. x. 23–25; Florus i. 11. For a critical examination of the story *see* Schwegler, *Römische Geschichte*, bk. xxviii. 12; E. Pais, *Storia di Roma*, i. ch. 4 (1898).

CINCLIDAE: *see* DIPPER.

CINDERELLA, the heroine of an almost universal fairy-tale (*i.e.*, little cinder girl). Its essential features are (1) the persecuted maiden whose youth and beauty bring upon her the jealousy of her step-mother and sisters; (2) the intervention of a fairy or other supernatural instrument on her behalf; (3) the prince who falls in love with and marries her. In the English version, a translation of Perrault's *Cendrillon*, the *glass* slipper which she drops on the palace stairs is due to a mistranslation of *pantoufle en vair* (a *fur* slipper), mistaken for *en verre*. It has been suggested that the story originated in a nature-myth, Cinderella being the dawn, oppressed by the night-clouds (cruel relatives) and finally rescued by the sun (prince).

See A. Lang, *Perrault's Popular Tales* (1888); Marian Rolfe Cox, *Cinderella; Three Hundred and Forty-five Variants* (1893).

CINEAS, a Thessalian, the chief adviser of Pyrrhus, king of Epirus. He was regarded as the most eloquent man of his age. He tried to dissuade Pyrrhus from invading Italy, and after the defeat of the Romans at Heraclea (280 B.C.) was sent to Rome to discuss terms of peace. These terms, which are said by Appian (*De Rebus Samniticis*, 10, 11) to have included the freedom of the Greeks in Italy and the restoration to the Bruttians, Apuljans and Samnites of all that had been taken from them, were rejected. Two years later Cineas was sent to renew negotiations on easier terms. The result was a cessation of hostilities, and Cineas crossed over to Sicily to prepare the ground for Pyrrhus's campaign. Nothing more is heard of him. He is said to have made an epitome of the *Tactica* of Aeneas, probably referred to by Cicero, who speaks of a Cineas as the author of a treatise *De Re Militari*.

See Plutarch, *Pyrrhus*, 11–21; Justin xviii. 2; Eutropius ii. 12; Cicero, *Ad Fam.* ix. 25.

CINEMATOGRAPHY: *see* MOTION PICTURES: *Technology*.

CINERARIA, cultivated ornamental plants originated from species of *Senecio*. There are two distinct types, the garden species, of which one of the most common is a Dusty Miller, *S. cineraria* and the greenhouse varieties of *S. cruentus*, commonly referred to as Cinerarias.

Greenhouse cinerarias are of two types: one a dwarf, compact growing plant with large flowers in dense clusters; the other a taller growing variety with larger, more spreading clusters of small star-shaped flowers. These are known horticulturally as stellate varieties of *Cineraria cruentus*. Both are easily grown from seed and are sold commercially as potted plants. The very free-flowering stellate varieties are more popular than are the large-flowered types and through a careful selection and crossing of varieties many beautiful colours are available.

For a succession of blooming plants during the late winter and spring months seeds are first sown in August in the cool greenhouse. As soon as the seedlings can be handled conveniently they are put in 2½″ pots. Later they are shifted to 3″ pots as the root system develops. The final shift into 6″ flowering pots is made early in January. Soil for cinerarias should be of a light, porous character and a mixture of one-half fibrous loam, one-half leaf mould with a liberal sprinkling of sharp sand suits them admirably. They grow best in a night temperature of from 45° to 50° F. with an increase of about 10° during the day. The soft succulent character of foliage and stems makes cinerarias especially liable to be attacked by green fly. The plants should be frequently fumigated with nicotine preparations or sprayed with nicotine solutions.

CINGOLI (anc. CINGULUM), a town of the Marches, Italy, province of Macerata, about 14 mi. N.W. direct, and 17 mi. by road from the town of Macerata. Pop. (1936) 1,751 (town); 15,496 (commune). Cingulum, a town of Picenum, founded by Caesar's lieutenant, T. Labienus, at his own expense in 63 B.C., played an important part in the civil wars owing to its lofty site (2,300 ft.).

Remains of the ancient city walls survive and there are interesting works of art in the Gothic church of S. Esuperanzio.

CINNA, a Roman patrician family of the gens Cornelia. The most prominent member was LUCIUS CORNELIUS CINNA, who, after serving in the war with the Marsi as praetorian legate, became consul in 87 B.C. After Sulla's departure for the East, riots broke out in Rome, and Cinna was expelled. He at once collected an army, Marius joined him, and the two captured Rome. Proscriptions followed, and the death of Marius (Jan. 86) left Cinna leader of the party. L. Valerius Flaccus became his colleague, and afterwards Cn. Papirius Carbo. In 84, however, Cinna, who was still consul, was forced to advance against Sulla; but while embarking his troops for Thessaly, he was killed in a mutiny. His daughter Cornelia was the wife of Julius Caesar, but his son, L. CORNELIUS CINNA, praetor in 44 B.C., sided with Caesar's murderers.

The hero of Corneille's tragedy *Cinna* (1640) was the Cn. Cornelius Cinna pardoned by Augustus for conspiracy.

CINNA, GAIUS HELVIUS, Roman poet of the later Ciceronian age, the friend of Catullus, whom he accompanied to Bithynia in the suite of the praetor Memmius. Suetonius, Valerius Maximus, Appian and Dio Cassius all state that, at Caesar's funeral, a certain Helvius Cinna was killed by mistake for Cornelius Cinna, the conspirator. The last three writers mentioned

above add that he was a tribune of the people, while Plutarch states that the Cinna who was killed by the mob was a poet. This points to the identity of Helvius Cinna the tribune with Helvius Cinna the poet. The chief objection to this view is based upon two lines in ninth eclogue of Virgil, supposed to have been written 41 or 40 B.C., which seem to imply that Helvius Cinna was then alive. But such an interpretation of the passage is not absolutely necessary. Cinna's chief work was a mythological epic poem called *Smyrna*. A *Propempticon Pollionis*, a send-off to (Asinius) Pollio, is also attributed to him. In both these poems, the language of which was so obscure that they required special commentaries, his model appears to have been Parthenius of Nicaea.

See A. Weichert, *Poëtarum Latinorum Vitae* (1830); L. Müller's edition of Catullus (1870), where the remains of Cinna's poems are printed; A. Kiessling, "De C. Helvio Cinna Poëta" in *Commentationes Philologicae in honorem T. Mommsen* (1878); O. Ribbeck, *Geschichte der römischen Dichtung*, i (1887); Teuffel-Schwabe, *Hist. of Roman Lit.* (Eng. trans. 213, 2–5); Plessis, *Poésie latine* (1909).

CINNABAR, sometimes written cinnabarite, is red mercuric sulphide (HgS), or native vermilion, the common ore of mercury (Ger. *Zinnober*). The name comes from the Greek κιννάβαρι, used by Theophrastus and probably applied to several distinct substances. Cinnabar is generally found in a massive, granular or earthy form, of bright red colour, but it occasionally occurs in crystals with a metallic adamantine lustre. The crystals belong to the hexagonal system and are generally of rhombohedral habit, sometimes twinned. Cinnabar presents remarkable resemblance to quartz in its symmetry and optical characters. Like quartz it exhibits circular polarization, and A. des Cloizeaux showed that it possessed 15 times the rotatory power of quartz (*see* LIGHT).

Cinnabar has a high refractive power, its mean index for sodium light being 3.08 (*see* REFRACTION). The hardness of cinnabar is 3, and its specific gravity 8. Cinnabar is the principal ore of mercury. The chief producing areas are Almaden, Sp., where it has been mined for 2,000 years, and Idria, It. The finest specimens come from Kweichow and Hunan, China. Hepatic cinnabar is an impure variety in which cinnabar is mixed with bituminous and earthy matter. Metacinnabar is a black cubic dimorphous form of mercury sulphide. (W. F. Fg.)

CINNAMIC ACID or Phenylacrylic Acid, is present in Peru and Tolu balsams, in storax and in some gum benzoins, combined with benzyl alcohol as an ester. Its formula is $C_6H_5.CH:CH.COOH$. It can be prepared by the reduction of phenyl propiolic acid with zinc and acetic acid, by heating benzal malonic acid, by the condensation of ethyl acetate with benzaldehyde in the presence of sodium ethoxide or by the so-called "Perkin reaction," which is the method commonly employed.

In this process benzaldehyde, acetic anhydride and anhydrous sodium acetate are heated to about 180° C.; the mixture is made alkaline with sodium carbonate, and excess of benzaldehyde removed by a current of steam. The residual liquor is acidified with hydrochloric acid. The cinnamic acid, which is precipitated, is then recrystallized from hot water. Cinnamic acid crystallizes in needles or prisms, melting at 133° C. It exists in two stereoisomeric varieties, one of which is trimorphous. On nitration it gives a mixture of ortho- and paranitrocinnamic acids, the former of which is of historical importance as by converting it into orthonitrophenylpropiolic acid A. Baeyer was enabled to carry out a complete synthesis of indigo (*q.v.*).

Cinnamic acid and its esters are employed in perfumes production. Various cinnamic acid preparations were used in the treatment of tuberculosis with disappointing results.

CINNAMON, the inner bark of *Cinnamomum zeylanicum*, a small evergreen tree belonging to the family Lauraceae, native to Ceylon. The leaves are large, ovate-oblong in shape, and the flowers, which are arranged in panicles, have a greenish colour and a rather disagreeable odour. The tree is grown at Tellicherry, in Java, the West Indies, Brazil and Egypt, but the produce of none of these places approaches in quality that grown in Ceylon. In 1940 imports of cinnamon oil into the United States were 184,673 lb., valued at $112,000. Ceylon cinnamon of fine quality is a very thin, smooth bark, with a light-yellowish brown colour, a highly fragrant odour and a peculiarly sweet, warm and pleasing aromatic taste. Its flavour results from an aromatic oil. This is prepared by pounding the bark, macerating it in sea water and then quickly distilling the whole. It is golden-yellow, with the peculiar odour of cinnamon and a hot aromatic taste. Cinnamon is principally employed in cookery as a condiment and flavouring material, being largely used in the preparation of some kinds of chocolate and liqueurs. It is also used in soap perfumes. Being a more costly spice than cassia, that comparatively harsh-flavoured substance is frequently substituted for or added to it.

CINNAMON STONE: *see* GARNET.

CINNAMUS (KINNAMOS), **JOHN,** Byzantine historian. He was imperial secretary to Manuel I Comnenus (1143–1180), whom he accompanied on his campaigns in Europe and Asia Minor. He appears to have outlived Andronicus I, who died in 1185. Cinnamus was the author of a history of the period 1118–76, which thus continues the *Alexiad* of Anna Comnena, and embraces the reigns of John II and Manuel I, down to the unsuccessful campaign of the latter against the Turks, which ended with the rout of the Byzantine army at Myriocephalum. Cinnamus was probably an eyewitness of the events of the last ten years which he describes. The work breaks off abruptly, and there are indications that it is an abridgement. The text is in a very corrupt state. The author's hero is Manuel; he is strongly impressed with the superiority of the east to the west, and is a determined opponent of the pretensions of the papacy; but he cannot be reproached with undue bias.

Byz.* (1836), with Du Cange's valuable notes; Migne, *Patrologia Graeca*, cxxxiii; *see* also H. von Kap-Herr, *Die abendländische Politik Kaiser Manuels* (1881); C. Neumann, *Griechische Geschichtsschreiber im 12 Jahrhundert* (1888); C. Krumbacher, *Geschichte der byzantinischen Litteratur* (1897).

CINO DA PISTOIA (1270–1336), Italian poet and jurist, whose full name was GUITTONCINO DE' SINIBALDI, was born in Pistoia, of a noble family. He studied law at Bologna under Dinus Muggelanus (Dino de Rossonis, d. 1303) and Franciscus Accursius, and in 1307 is understood to have been assessor of civil causes in his native city. In that year, however, Pistoia was disturbed by the Guelph and Ghibelline feud. Cino was a Ghibelline, and had to leave Pistoia. Pitecchio, a stronghold on the frontiers of Lombardy, was yet in the hands of Filippo Vergiolesi, chief of the Pistoian Ghibellines; Selvaggia, his daughter, was beloved by Cino (who was probably already the husband of Margherita degli Unghi); and Cino betook himself to Pitecchio. He was not with the Vergiolesi at the time of Selvaggia's death (1310) at the Monte della Sambuca, in the Apennines, whither the Ghibellines had been compelled to shift their camp. In 1313 the emperor died, and the Ghibellines lost their last hope. Cino appears to have thrown up his party and to have returned to Pistoia. Thereafter he devoted himself to law and letters. After filling several high judicial offices, a doctor of civil law of Bologna in his 44th year, he lectured and taught from the professor's chair at the universities of Treviso, Siena, Florence and Perugia in succession.

Cino, the master of Bartolus and of Joannes Andreae, the celebrated canonist, was long famed as a jurist. His commentary on the statutes of Pistoia, written in two years, is said to have great merit; while that on the code (*Lectura Cino Pistoia super codice*, Pavia, 1483; Lyons, 1526) is considered by Savigny to exhibit more practical intelligence and more originality of thought than are found in any commentary on Roman law since the time of Accursius. He was the friend and correspondent of Dante's later years, and possibly of his earlier also, and was certainly, with Guido Cavalcanti and Durante da Maiano, one of those who replied to the famous sonnet *A ciascun' alma presa e gentil core* of the *Vita Nuova*. In the treatise *De Vulgari Eloquio* Dante refers to him as one of "those who have most sweetly and subtly written poems in modern Italian." Petrarch coupled Cino and Selvaggia with Dante and Beatrice in the fourth chapter of his *Trionfi d'Amore*. As a poet Cino has moments of true passion and fine natural eloquence. Of these qualities the sonnet in memory of Selvaggia, *Io fui in sull' alto e in sul beato monte*, and the canzone to Dante, *Avengnachè di omaggio più per tempo*, are interesting examples.

The textbook for English readers is D. G. Rossetti's *Early Italian Poets*, which contains a memoir of Cino da Pistoia and some admirably translated specimens of his verse. *See* also Ciampi, *Vita e poesie di messer Cino da Pistoia* (Pisa, 1813).

CINQ-MARS, HENRI COIFFIER RUZÉ D'EFFIAT, MARQUIS DE (1620–1642), French courtier, was the second son of Antoine Coiffier Ruzé, marquis d'Effiat, marshal of France (1581–1632), and was introduced to the court of Louis XIII by Richelieu, who had been a friend of his father and who hoped he would counteract the influence of the queen's favourite, Mlle. de Hautefort. He became the king's accredited favourite, master of the wardrobe and master of the horse. After distinguishing himself at the siege of Arras in 1640, Cinq-Mars became restive. He had fallen in love with Louise Marie de Gonzaga, afterward queen of Poland, who was not disposed to favour a suitor who could not satisfy her ambition. Cinq-Mars demanded a high military command, but Richelieu opposed his pretensions and the favourite talked rashly about overthrowing the minister. He was probably connected with the abortive rising of the count of Soissons in 1641; however that may be, in the following year he formed a conspiracy with the duke of Bouillon and others to overthrow Richelieu. This plot was under the nominal leadership of the king's brother, Gaston of Orléans. The plans of the conspirators were aided by the illness of Richelieu and his absence from the king, and at the siege of Narbonne Cinq-Mars almost induced Louis to agree to banish his minister. Richelieu, however, recovered; Gaston betrayed the conspirators, and Richelieu laid before the king the proofs of the treasonable negotiations of the conspirators for assistance from Spain. Cinq-Mars was tried, admitted his guilt and was executed at Lyons on Sept. 12, 1642. His conspiracy was the subject of A. de Vigny's novel *Cinq-Mars*.

See D'Hancour, *La Conspiration de Cinq-Mars* (1902); Vicomtesse de Gallard, *Lettres de Bullion et de Richelieu* (Paris, 1903).

CINQUECENTO, a term used to describe that period of the Italian Renaissance between 1500 and 1600. The word is often applied to the artistic styles prevalent at that time, and particularly to the classicism of the high Renaissance.

CINQUEFOIL, a decorative form of five lobes or cusps.

CINQUE PORTS, the name of an association of maritime towns in the southeast of England, exercising a jurisdiction dating from about the time of the Norman conquest, organized, it seems on French lines, in the 13th century, and still surviving. The ports originally constituting the body were only five in number—Hastings, Romney, Hythe, Dover and Sandwich; but to these were afterward added the "ancient towns" of Winchelsea and Rye with the same privileges, and other places, both corporate and noncorporate, which, with the title of limb or member, held a subordinate position. To Hastings were attached the corporate members of Pevensey and Seaford and the noncorporate members of Bulvarhythe, Petit Iham (Yham or Higham), Hydney, Bekesbourn, Northeye and Grenche or Grange; to Romney, Lydd, and Old Romney, Dengemarsh, Orwaldstone and Bromehill or Promehill; to Dover, Folkestone and Faversham, and Margate, St. John's, Goresend (now Birchington), Birchington Wood (now Woodchurch), St. Peter's, Kingsdown and Ringwould; to Sandwich, Fordwich and Deal, and Walmer, Ramsgate, Reculver, Stonor (Estanor), Sarre (or Serre) and Brightlingsea (in Essex). To Rye was attached the corporate member of Tenterden, and to Hythe the noncorporate member of West Hythe. The jurisdiction thus extends from Seaford in Sussex to Birchington near Margate in Kent, and includes part of the Essex coast.

The duty of the Cinque Ports until the reign of Henry VII was to furnish nearly all the ships and men that were needful for the king's service; and for a long time after they were required to give large assistance to the permanent fleet. In return for their services the ports enjoyed extensive privileges (*cf.* S. Jeake's *Charters of the Cinque Ports*, still the chief authority).

The highest office in connection with the Cinque Ports is that of the lord warden, who is also constable of Dover castle; the two offices have for centuries been held by the same persons, but are still distinct. He has a maritime jurisdiction as admiral of the ports. His power was formerly of great extent, but he has now practically no important duty to exercise. Walmer castle was for long the official residence of the lord warden, and its use as such, though intermittent, is not obsolete. In 1941 King George VI appointed Winston Churchill lord warden.

The court of admiralty for the Cinque Ports exercises a coordinate but not exclusive admiralty jurisdiction over persons and things found within the territory of the Cinque Ports. At an inquisition taken at the court of admiralty, held by the seaside at Dover in 1682, the limits of its jurisdiction were declared to extend from Shore Beacon in Essex to Redcliff, near Seaford, in Sussex; and with regard to salvage, they were to comprise all the sea between Seaford in Sussex to a point five miles off Cape Grisnez on the coast of France, and the coast of Essex. An older inquisition of 1526 is given by R. G. Marsden in his *Select Pleas of the Court of Admiralty*, II, xxx (London, 1894). The judge sits as the official and commissary of the lord warden, just as the judge of the high court of admiralty sat as the official and commissary of the lord high admiral. And, as the office of lord warden is more ancient than the office of lord high admiral (*The Lord Warden* v. *King in his office of Admiralty*, 1831, 2 Hagg. Admy. Rep. 438), it is probable that the Cinque Ports' court is the more ancient of the two.

The jurisdiction of the court is in theory concurrent with that of the king's court of admiralty, subject to some statutory modifications. Cases of collision have been tried in it (the "Vivid," 1 *Asp. Maritime Law Cases*, 601), but of late mainly salvage cases (the "Clarisse," *Swabey*, 129; the "Marie," *Law. Rep.* 7 P.D. 203).

Robert Joseph Phillimore succeeded his father as judge of the court from 1855 to 1875. As he was also the last judge of the high court of admiralty, from 1867 (the date of his appointment to the high court) to 1875, the two offices were, probably for the only time in history, held by the same person. His patent had a grant of the "place or office of judge official and commissary of the court of admiralty of the Cinque Ports, and their members and appurtenances, and to be assistant to my lieutenant of Dover castle in all such affairs and business concerning the said court of admiralty wherein yourself and assistance shall be requisite and necessary." Of old the court sat sometimes at Sandwich, sometimes at other ports, but the regular place for the sitting of the court was for a long time St. James's church, Dover. For convenience the judge later sat at the royal courts of justice, but the last full sitting was in 1914. The office of marshal in the high court is represented in this court by a sergeant, who also bears a silver oar.

The registrar who, according to general civilian practice, can act as the judge's deputy, deals at Dover with the small matters which keep the jurisdiction alive. An appeal is to the king in council, advised by the judicial committee. For details of the jurisdiction *cf.* the Cinque Ports act, 1821. The judge's only active duty is to take part in the installation of a new lord warden.

The Cinque Ports from the earliest times claimed to be exempt from the jurisdiction of the admiral of England. Their early charters do not, like those of Bristol and other seaports, express this exemption in terms. It seems to have been derived from the general words of the charters which preserve their liberties and privileges.

The lord warden's claim to prize was raised in, but not finally decided by, the high court of admiralty in the "Ooster Ems," 1 C. Rob. 284, 1783. No trace was found of any later attempt to assert it.

Ports Jurisdiction," *Law Quart. Rev.*, 41:453 (London). The archives of the Cinque Ports are not gathered together in one place; the chief repositories are at New Romney, Dover and Rye.

CINTRA, town of central Portugal (modern spelling, Sintra), 17 mi. W.N.W. of Lisbon by the Lisbon-Caçem-Cintra railway and 6 mi. N. by E. of Cape da Roca, the westernmost promontory of the European mainland. Pop. (1950) 7,150. Cintra is magnificently situated on the northern slope of the Serra da Cintra, a rugged mountain mass, largely overgrown with pines, eucalyptus, cork and other forest trees, above which the principal summits rise in a succession of bare and jagged gray peaks, the highest being Cruz Alta (1,736 ft.). Every educated Portuguese is familiar with the verses in which the beauty of Cintra is celebrated by Byron in *Childe Harold* (1812), and by Camoens in the national epic *Os Lusiadas* (1572). One of the highest points of the Serra is surmounted by the Palacio da Pena, a fantastic imitation of a mediaeval fortress, built on the site of a Hieronymite convent by the prince consort Ferdinand of Saxe-Coburg (d. 1885); while an adjacent part of the range is occupied by the Castello des Mouros, an extensive Moorish fortification containing a small ruined mosque and a very curious set of ancient cisterns.

In the town itself the most conspicuous building is a 14th–15th-century royal palace, partly Moorish, partly debased Gothic in style, and remarkable for the two immense conical chimneys. The 18th-century Palacio de Seteaes is said to derive its name ("Seven Ahs") from a sevenfold echo; here, on Aug. 22, 1808, was signed the convention of Cintra, by which the British and Portuguese allowed the French army to evacuate the kingdom. Beside the road which leads for 3½m. W. to the village of Collares, celebrated for its wine, is the Penha Verde, an interesting country house and chapel, founded by Dom João de Castro (1500–1548), fourth viceroy of India. Castro also founded the Capuchin convent of Santa Cruz, better known as the Cork convent. Beyond the Penha Verde, on the Collares road, are the palace and park of Montserrate. The palace was originally built by William Beckford, the novelist and traveller (1761–1844), and was purchased in 1856 by Sir Francis Cook, an Englishman, who afterwards obtained the Portuguese title viscount of Montserrate. The park, with its tropical luxuriance of vegetation and its variety of lake, forest and mountain scenery, is by far the finest example of landscape gardening in the Iberian Peninsula, and probably among the finest in the world.

CIPHER or **CYPHER,** the symbol o, nought, or zero (Arab. *ṣifr*, void), and so a name for symbolic or secret writing (*see* CODES AND CIPHERS), or for shorthand (*q.v.*), and also in elementary education for doing simple sums ("ciphering").

CIPPUS (Lat. for a "post" or "stake"), in architecture, a low pedestal, either round or rectangular, set up by the Romans for various purposes such as military or mile stones, boundary posts, etc. The inscriptions on some in the British Museum show that they were occasionally funeral memorials.

CIPRIANI, GIOVANNI BATTISTA (1727–1785), Italian painter and engraver, Pistoiese by descent, was born in Florence in 1727. He studied first under Ignatius Heckford or Hugford, and afterwards under Antonio Domenico Gabbiani. He was in Rome from 1750 to 1753, where he became acquainted with Sir William Chambers, the architect, and Joseph Wilton, the sculptor, whom he accompanied to England in Aug., 1755. When Chambers designed the Albany in London for Lord Holland, Cipriani painted a ceiling for him. He also painted part of a ceiling in Buckingham Palace, and a room with poetical subjects at Standlynch in Wiltshire. Some of his best and most permanent work was, however, done at Somerset House, London, built by his friend Chambers. He not only prepared the decorations for the interior of the north block, but, says Joseph Baretti in his *Guide through the Royal Academy* (1780), "the whole of the carvings in the various fronts of Somerset place—excepting Bacon's bronze figures—were carved from finished drawings made by Cipriani." These designs include the five masks forming the keystones to the arches on the courtyard side of the vestibule, and the two above the doors leading into the wings of the north block, all of which are believed to have been carved by Nollekens. The grotesque groups flanking the main doorways on three sides of the quadrangle and the central doorway on the terrace appear also to have been designed by Cipriani. The central panel of the library ceiling was painted by Sir Joshua Reynolds, but the four compartments in the coves, representing Allegory, Fable, Nature and History, were Cipriani's. These paintings still remain at Somerset House, together with the emblematic painted ceiling, also his work, of what was once the library of the Royal Society. He was an original member of the Royal Academy (1768), for which he designed the diploma so well engraved by Bartolozzi. He was much employed by the publishers, for whom he made drawings in pen and ink, sometimes coloured. His friend Bartolozzi engraved most of them. Drawings by him are in both the British Museum and Victoria and Albert Museum, London. His best autograph engravings are "The Death of Cleopatra," after Benvenuto Cellini; "The Descent of the Holy Ghost," after Gabbiani; and portraits for Hollis's memoirs, 1780. He painted allegorical designs for George III.'s state coach—which is still in use—in 1761, and repaired Verrio's paintings at Windsor and Rubens's ceiling in the Banqueting House at Whitehall. He designed nymphs and *amorini* and medallion subjects to form the centre of Pergolesi's bands of ornament, and they were continually reproduced upon the elegant satin-wood furniture which was growing popular in his later days. Almost certainly some of the beautiful furniture designed by the Adams was actually painted by Cipriani himself. He also occasionally designed handles for drawers and doors. Cipriani died at Hammersmith in 1785 and was buried at Chelsea, where Bartolozzi erected a monument to his memory. He had married an English lady, by whom he had two sons.

CIRCAR, an Indian term applied to the component parts of a *subah*, or province, each of which is administered by a deputy-governor. In English it is principally employed in the name of the Northern Circars, used to designate a now obsolete division of the Madras presidency, which consisted of a narrow slip of territory lying along the western side of the bay of Bengal from 15° 40′ to 20° 17′ N. lat. These Northern Circars were five in number, Chicacole, Rajahmundry, Ellore, Kondapalli and Guntur, and their total area was about 30,000 sq. miles.

The district corresponds in the main to the modern districts of Kistna, Godavari, Vizagapatam, Ganjam and a part of Nellore. It was first invaded by the Mohammedans in 1471 and conquered by them in the following century, but they appear to have acquired only an imperfect possession of the country, as it was again wrested from the Hindu princes of Orissa about the year 1571. In 1687 the Circars were added, along with the empire of Hyderabad, to the empire of Aurangzeb. In 1759, by the conquest of Masulipatam, the dominion of the maritime provinces on both sides, from the river Gundlakamma to the Chilka lake, was transferred from the French to the British. But the latter left them under the administration of the nizam, with the exception of the town and fortress of Masulipatam, which were retained by the English East India company. In 1765 Lord Clive obtained from the Mogul emperor Shah Alam a grant of the five Circars. Hereupon the fort of Kondapalli was seized by the British, and in 1766 a treaty of alliance was signed with Nizam Ali, by which the company, in return for the grant of the Circars, undertook to maintain troops for the nizam's assistance. By a second treaty, signed in 1768, the nizam acknowledged the validity of Shah Alam's grant and resigned the Circars to the company, receiving as a mark of friendship an annuity of £50,000. Guntur, as the personal estate of the nizam's brother, was excepted during his lifetime under both treaties. He died in 1782, but it was not till 1788 that Guntur came under British administration. In 1823, the claims of the nizam over the Northern Circars were bought out by the company, and they became a British possession.

CIRCASSIA: *see* CAUCASIAN AREA, NORTH; KARACHAEV; KABARDA-BALKARIA; INGUSHETIA; ADIGEI.

CIRCASSIANS. The Cherkesses or Circassians differ from the other tribes of the Caucasus in origin and language. They designated themselves by the name of Adigheb, that of Cherkesses

being a term of Russian origin. The government under which they lived was a peculiar form of the feudal system. The free Circassians were divided into three distinct ranks, the princes or *pshi*, the nobles or *uork* (Tatar *usden*), and the peasants or *hokotl*. They were also divided into numerous families, tribes or clans, some of which were very powerful and carried on war against each other with great animosity. The slaves, of whom a large proportion were prisoners of war, were generally employed in the cultivation of the soil, or in the domestic service of some of the principal chiefs.

The will of the people was the supreme source of authority; and every free Circassian had a right to express his opinion in those assemblies of his tribe in which the questions of peace and war, almost the only subjects which engaged their attention, were brought under deliberation. The princes and nobles, the leaders of the people in war and their rulers in peace, were only the administrators of a power which was delegated to them. The administration of justice was regulated solely by custom and tradition, and in those tribes professing Mohammedanism by the precepts of the Koran. The most aged and respected inhabitants of the various auls or villages frequently sat in judgment, and their decisions were received without a murmur by the contending parties. The Circassian princes and nobles were professedly Mohammedans; but in their religious services many of the ceremonies of their former heathen and Christian worship were still preserved. A great part of the people had remained faithful to the worship of their ancient gods—Shible, the god of thunder, of war and of justice; Tleps, the god of fire; and Seosseres, the god of water and of winds. One of their marriage ceremonies was that the young man who had been approved by the parents, and had paid the stipulated price in money, horses, oxen, or sheep for his bride, was expected to come with his friends fully armed and to carry her off by force from her father's house. Every free Circassian had unlimited right over the lives of his wife and children. Although polygamy was allowed by the laws of the Koran, the custom of the country forbade it. The respect for superior age was carried to such an extent that the young brother used to rise from his seat when the elder entered an apartment, and was silent when he spoke. Circassians were distinguished for the most generous hospitality and implacable vindictiveness. The individual who had slain any member of a family was pursued with implacable vengeance by the relatives, until his crime was expiated by death. The murderer might, indeed, secure his safety by the payment of a certain sum of money, or by carrying off from the house of his enemy a newly-born child, bringing it up as his own and restoring it when its education was finished. In either case, the family of the slain individual might discontinue the pursuit of vengeance without any stain upon its honour. The man closely followed by his enemy, who, on reaching the dwelling of a woman, had merely touched her hand, was safe from all other pursuit so long as he remained under the protection of her roof. The commission of theft was not considered so disgraceful as its discovery. The Circassian father was always willing to part with his daughters to Turkish merchants for the harems of Eastern monarchs. But no degradation was implied in this transaction, and the young women themselves were generally willing partners in it. Herds of cattle and sheep constituted the chief riches of the inhabitants. The princes and nobles, from whom the members of the various tribes held the land which they cultivated, were the proprietors of the soil. The Circassians carried on little or no commerce.

CIRCE, in Greek legend, a famous sorceress, the daughter of Helios and the ocean nymph Perse. She was able by means of drugs and incantations to change human beings into the forms of wolves or lions, and with these beings her palace was surrounded. Odysseus visited her island, Aiaie, with his companions, whom she changed into swine, but the hero, protected by the herb *molu*, which he had received from Hermes, compelled her to restore them to their original shape. He lived with her for a year, and when he determined to leave, she instructed him how to sail to the House of Hades in order to learn his fate from the prophet Teiresias. Upon his return she also gave him directions for avoiding the dangers of the journey home (Homer, *Odyssey*, x.–xii.; Hyginus, *Fab.* 125). Graeco-Italian tradition placed her island near Italy, or located her on the promontory Circei. *Cf.* Picus, Scylla and Charybdis.

See C. Seeliger in W. H. Roscher's *Lexikon der Mythologie*.

CIRCEIUS MONS (mod. Monte Circeo), an isolated promontory on the south-west coast of Italy, about 80m. S.E. of Rome. It is a ridge of limestone about 3½m. long by 1m. wide at the base, running from east to west and surrounded by the sea on all sides except the north. The land to the north of it is 53ft. above sea-level, while the summit of the promontory is 1,775ft. The origin of the name is uncertain: it has naturally been connected with the legend of Circe. It is true that the promontory ceased to be an island at a very early date; but it looks exactly like one from a distance. Upon the east end of the ridge are the remains of an *enceinte*, forming a rectangle of about 200 by 100yds. of very fine polygonal work. It seems to have been an acropolis, and contains no traces of buildings, except for a subterranean cistern, circular, with a beehive roof of converging blocks. The modern village of S. Felice Circeo occupies the site of the ancient town, the citadel of which stood on the mountain top, for its mediaeval walls rest upon ancient walls of Cyclopean work of less careful construction than those of the citadel, and enclosing an area of 200 by 150yds.

Circeii was founded as a Roman colony at an early date. At the end of the republic, the city of Circeii was no longer at the east end of the promontory, but at the south end of the Lago di Paola (a lagoon—now a considerable fishery—separated from the sea by a line of sandhills and connected with it by a channel of Roman date; Strabo speaks of it as a small harbour). The transference of the city did not, however, mean the abandonment of the east end of the promontory, on which stand the remains of several very large villas. An inscription, indeed, cut in the rock near S. Felice, speaks of this part of the *promonturium Veneris* (the only case of the use of this name) as belonging to the city of Circeii. For its villas Cicero compares it with Antium, and both Tiberius and Domitian possessed residences there. The villa of the latter indeed, on the east shores of the Lago di Paola, has been mistaken for the Roman town of Circeii. It extends over an area of some 600 by 500yds., consisting of fine buildings along the lagoon, including a large open *piscina* or basin, surrounded by a double portico, while farther inland are several very large and well-preserved water-reservoirs, supplied by an aqueduct of which traces may still be seen. The beetroot and oysters of Circeii had a certain reputation.

The view from the highest summit of the promontory (which is occupied by ruins of a platform attributed with great probability to a temple of Venus or Circe) is of remarkable beauty; the whole mountain is covered with fragrant shrubs. From any point in the Pomptine Marshes or on the coast-line of Latium the Circeian promontory dominates the landscape in the most remarkable way.

See G. Lugli, *Forma Italiae* 1. i. 2. (1928), the Italian archaeological survey.

CIRCLE, a curve consisting of all those points of a plane which lie at a fixed distance from a particular point in the plane, called the *centre*.

The circle is the simplest and most useful *plane curve* and alone possesses the property of being exactly alike at all points. If the curve be turned in its plane about its centre, the new position taken up is the same as the original position. This property constitutes the "roundness" of the circle, and distinguishes it from other plane curves. A circle may be traced upon a plane by the continuous movement of a point rigidly connected with the centre, as in the use of compasses, and it is in part the simplicity of this construction which explains the fundamental importance of this curve. The tracing of a circle is a much simpler problem than the tracing of a straight line, since the common method of drawing the latter, with the aid of a ruler, only reproduces the straight line already constructed along the ruler's edge. A difference in the use of the word "circle" is observable between the older writers and those of the present century. With the former

the word is understood to mean the part of the plane enclosed by the curve, while the curve itself is called the *circumference*. The latter consider the circle and its circumference identical, except that the latter is often spoken of as the measure of the former; and the enclosed portion of the plane is spoken of as the *interior*, not as the circle itself.

The straight line joining the centre to a point on the circle, *e.g.*, *OP* or *OQ* (fig. 1) is called a *radius*; from the definition of a circle, the radii drawn to various points on the circle are equal. A straight line drawn through the centre and having its ends on the circle, *e.g.*, *EOH* (fig. 1) is called a *diameter*; evidently all diameters of the same circle are equal in length, and twice as long as a radius. A straight line, such as *ABC* (fig. 1), joining *any* two points on a circle is called a chord; and the greatest possible chord is a diameter. The portion of the circle intercepted between two points is called an *arc*. Any two points on the circle divide it into two arcs; thus, in fig. 1, *ADC* is the *minor arc*, and *APEC* the *major arc*, between *A* and *C*. The figure composed of an arc and the chord joining its extremities is a *segment* of the circle. In fig. 1, *ADCB* and *APECB* are respectively the minor and major segments made by the chord *AC*. A *sector* of a circle is the figure formed by two radii and one of the arcs joining their extremities. The angle between these radii and within the sector is called the angle of the sector. Thus *ODKC* (fig. 1) is a sector, and *DOC* its angle.

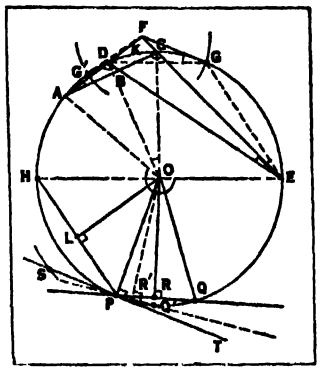

FIG. 1.—THE CIRCLE AND ITS PARTS Showing the radius OP or OQ, diameter EOH, chord ABC, minor arc ADC, major arc APEC, minor and major segments ADCB and APECB, sector ODKC and the angle of sector DOC

Geometrical Properties.—A number of properties of the circle are direct results of the symmetry and regularity of the curve. For instance, if two chords in the same circle are equal, the arcs corresponding to them are equal; if two sectors of the same circle have equal angles, they have equal arcs, and contain equal areas, etc. A useful property of this kind is that *every chord is bisected by the perpendicular drawn to it from the centre*. This allows the centre to be found when the circle is given, and to draw the circle when three points on it are given. Thus, to construct the circle through *H*, *P* and *Q*, draw the perpendicular bisectors *LO* and *RO* to *HP* and *PQ* as in fig. 1, and take as centre the point *O* where these meet.

A less evident property is that, *when any arc is taken, the angle between the lines joining its end-points to the centre is double the angle between the lines joining these end-points to any point on the remaining part of the circle, each angle being measured in the position facing the arc*. In fig. 1, by using the minor arc *CD*, the angle *COD* is double the angle *CED*, and also double the angle *CAD*. By using the major arc *APE*, the outer (reflex) angle *AOE* is double either *ACE* or *ADE*. An immediate consequence is that the angle *ACE* is equal to the angle *ADE*. Here *A*, *C*, *D* and *E* are any four points on a circle so placed that *C* and *D* lie on the same arc having *A* and *E* for end-points. The theorem is commonly stated in the form: *angles in the same segment are equal*. (To exhibit the segment it is necessary to join *AE*.) It is a property of wide application, and numerous instances of it may be seen in fig. 1 by joining various pairs of points. Thus the angles *CAD*, *CED*, *CGD*, *CQD* (when the lines *CQ*, *QD* and *CG* are drawn), are equal. In particular, *the angle in a semi-circle is a right angle*. Closely related to this is the theorem that *a four-sided figure whose four corners all lie on the same circle has the sum of either pair of opposite angles equal to two right angles*. The converse is true that if the sum of one of the pairs of opposite angles of a four-sided plane figure is two right angles, a circle may be drawn to pass through the four corners.

It is readily seen that a straight line whose shortest distance from the centre is less than the radius cuts a circle in two points, and that a line whose shortest distance is greater than the radius does not meet the circle at any point. The intermediate case occurs when the line is at a distance from the centre equal to the radius, as is the case with *SPT* (fig. 1). Such a line has only one point in common with the circle; it is said to *touch* the circle and is called a *tangent* to the circle. The tangent at any point of a circle is the line through that point drawn at right angles to the radius; thus *OPT* is a right angle. The tangent at *P* is the limiting position approached by a chord *PQ*, drawn through *P*, as the other extremity *Q* approaches *P*. The chord must be prolonged as shown in the figure, in order that it may not be lost as its length vanishes. It is known that the perpendicular *OR* from the centre falls on the middle point of the chord. As *Q* moves to *Q'*, *R* moves to *R'*, and, as *Q* approaches *P*, *R* approaches *P* also. Finally the right angle *ORQ* approaches the limiting position *OPT*, and the chord *PQ*, prolonged sufficiently, is finally represented by the tangent *PT* at right angles to the radius *OP*. This second view of a tangent, as the limiting form of a short chord, is more generally applicable than the former, being valid for curves other than circles. It also enables many tangent theorems to be recognized as the limiting forms of related theorems on chords, and leads to a better understanding of tangent relations.

From a point *F* outside a circle two tangents may be drawn. The *points of contact G* and *G'* of these may be found by first drawing the tangent at a point *P* on the circle, finding with the compasses a point *S* on this such that *OS*=*OF*, and then finding *G* and *G'* on the circle and at distance from *F* equal to *PS*. *The angle made by a tangent with a chord through its point of contact is equal to the angle in the segment on the other side of the chord*. Thus the angle *FGD* is equal to the angle *GED*. An important theorem on intersecting chords follows readily from the law of equal angles in a segment. *If two chords intersect, the product of the distances of the extremities from the point of intersection is the same for either chord*. Thus, in fig. 1, *AC* and *DE* intersect at *B*. The figure represents the case where *AB* contains 4·5 units, *BC* 3·2 units, *DB* 1 unit, and *BE* 14·4. It will be seen that 4·5×3·2=1×14·4. The relation remains true when the chords have to be prolonged to meet outside the circle, as *AD* and *CE*, meeting at *F*. In the figure *AF*=7·2, *DF*=3·2, *CF*=1·6 and *EF*=14·4, so that *AF*×*DF*=*CF*×*EF*, each being 23·04. In the case of external intersection each of the equal products is also equal to the *square of the tangent from the point of intersection*. In the figure, *FG*=4·8, the square of which is 23·04. This is one of the cases where the tangent represents a chord whose ends are coincident.

Circle Constructions.—The circle plays an important part in the problems of constructive geometry. This will be easily understood when it is remembered that, in the traditional view, a geometrical solution means a solution by ruler and compasses; that is, the only steps available are to rule a straight line through two given points and to draw a circle having a given centre and radius. It is therefore a matter of importance to the student of geometry to be able to construct circles to satisfy various standard sets of conditions; and several of these processes will be indicated briefly:

1. *Circle through three given points.* The method of finding the centre by the right bisectors of the joining lines has already been given. When the three points are thought of as the corners of a triangle, the circle is said to be *circumscribed* to the triangle.

2. *Circle touching three given straight lines.* Bisect the angles between two of the lines *l* and *m*, obtaining a pair of bisector lines *a* and *b*. Bisect in the same way the angles between *l* and the third line *n* by a pair of bisectors *c* and *d*. The centre of a circle touching *l* and *m* must be equidistant from *l* and *m*, and so must lie either on *a* or on *b*. The centre of a circle touching *l* and *n* must be either on *c* or on *d*. Four solutions are obtained, the positions of the centre being the intersections of *a* and *c*, of *a* and *d*, of *b* and *c*, and of *b* and *d*. The circle that lies between the given lines and touches them is said to be *inscribed* to the triangle.

3. *Circle through two given points and touching a given line* (which does not pass between the points). Let *A* and *B* be the

given points, and l the given line (fig. 2). Let AB cut l in O. Draw any circle c through A and B, by taking as centre any point on the right bisector of AB. Draw the tangent OT touching c at T. Find points H and K on l so that $KO=OH=OT$. The circle c_1 through A, B and H and the circle c_2 through A, B and K will each be a solution of the problem. The proof is briefly that $OH^2=OK^2=OT^2=OA.OB$, so that OH and OK are each of the right length for a tangent from O.

4. *Circle through a given point and touching two given lines.* Let l and m (fig. 2) be the given lines, and A the given point. Draw n, the bisector of that angle between l and m in which A lies. Draw AL perpendicular to n and prolong to B so that $LB=AL$. The circles c_1 and c_2 constructed as in 3 to pass through A and B and to touch l will then constitute the two solutions of the problem.

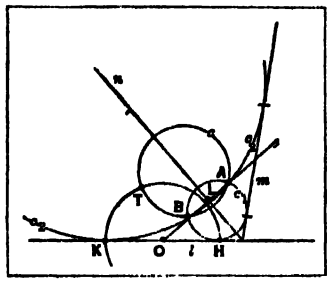

FIG. 2.—SHOWING THE CONSTRUCTION OF A CIRCLE THROUGH TWO GIVEN POINTS AND TOUCHING A GIVEN LINE, AND THROUGH A GIVEN POINT TOUCHING TWO GIVEN LINES

Circle constructions in which some of the conditions are that the circle should touch certain given circles require refined geometrical methods. A celebrated case of this type is Apollonius's problem: —*to construct a circle to touch three given circles.* If the three circles are entirely external to one another, this problem admits of eight solutions. A number of problems of this kind, due to Jakob Steiner and others, are discussed by Coolidge (*see* bibl.). It is often useful to remember that a circle through two given points may have its centre anywhere on the right bisector of their joining line, and that a circle touching two given intersecting straight lines has its centre anywhere on either of the lines bisecting the angles between them. A circle through a given point and touching a given line has its centre on a curve known as a parabola; but this fact is not of much direct assistance in finding constructions.

In many cases a point moving under specified conditions traces a circular path. The definition of the circle shows that this curve is the *locus* (or path) of a variable point whose distance from a fixed point remains constant. But there are numerous other ways in which the circular path may be recognized. If the base of a triangle is fixed, and the angle at the vertex is of constant magnitude, the moving vertex traces an arc of a circle as long as it remains on the same side of the fixed base; the property involved here is that of equal angles in a segment. If the base of a triangle is fixed, and the other two sides are in constant ratio, the moving vertex traces a circle which encloses one of the fixed vertices. If the sum of the squares of the distances of a variable point from two fixed points is constant, the point traces to a circle whose centre is half-way between the two fixed points.

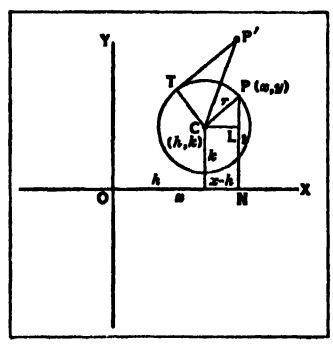

FIG. 3. ANALYSIS OF THE CIRCLE TO DETERMINE ITS EQUATION

Analytic Treatment.—We may take for axes of reference two lines OX and OY at right angles; and, drawing PN perpendicular to OX from any point P, denote by x and y the measurements ON and NP. The two quantities x and y are called the co-ordinates of P, and the position of P depends on their values. the point P is denoted by (x, y). If C is a fixed point (h, k), P will be restricted to a circle of centre C and radius r provided $CP=r$; *i.e.*, $CP^2=r^2$, or $CL^2+LP^2=r^2$, if CL is perpendicular to NP; therefore

$$(x-h)^2+(y-k)^2=r^2 \qquad (1)$$

This is the *equation of the circle.* The variable point P will lie on the circle if, and only if, (1) is satisfied.

The equation $x^2+y^2+2ax+2by+c=0$.....(2)

may be written in the form $(x+a)^2+(y+b)^2=a^2+b^2-c$, which is equivalent to (1) if $h=-a$, $k=-b$ and $r^2=a^2+b^2-c$. The last of these conditions is not possible for any real value of r if a^2+b^2-c is negative; but, if a^2+b^2-c is positive, the equation (2) is seen to represent a circle whose centre is $(-a,-b)$ and *radius* $\sqrt{(a^2+b^2-c)}$. The constants a, b and c in (2) may be determined to satisfy specified conditions, and the circle becomes then definitely fixed. For instance, if the circle is to pass through three given points, the co-ordinates of these must satisfy the equation (2), and, on substituting them for x and y, three equations are obtained giving a, b and c. If the point (x, y) is not on the circle, but outside it, as at P' (fig. 3), the left-hand side of equation (2) is *not* equal to zero, but, when written as $(x+a)^2+(y+b)^2-(a^2+b^2-c)$, or $(x-h)^2+(y-k)^2-r^2$, is seen to represent CP'^2-CT^2 (if $P'T$ is a tangent), which is $P'T^2$.

A point (x, y) from which the tangent to the circle (2) is equal to the tangent to the circle $x^2+y^2+2a'x+2b'y+c'=0$.....(3) satisfies the equation

$$x^2+y^2+2ax+2by+c=x^2+y^2+2a'x+2b'y+c';$$
$$i.e.,\ 2(a-a')x+2(b-b')y+(c-c')=0.$$

This equation (if the circles (2) and (3) have not the same centre) is of the first degree, so that the point (x, y) lies on a fixed straight line, called the *radical axis* of the circles. If the circles (2) and (3) have two points in common, the radical axis is the line joining these points. The equation $x^2+y^2+2kx+c=0$ represents, for different values of c, different circles of which any two have OY for radical axis. These circles are said to form a *coaxial system.* If c is negative, all the circles pass through the same two points on OY. If c is positive, none of the circles intersect. In either case one circle of the system may be found to pass through any given point not on OY.

The equation of the tangent at a point (x_1, y_1) on the circle (2) may be shown to be

$$x_1x+y_1y+a(x+x_1)+b(y+y_1)+c=0. \qquad (4)$$

If, however, (x_1, y) is not on, but outside the circle, equation (4) represents the *polar* of (x_1, y_1) that is the straight line joining the points of contact of tangents from (x_1, y_1).

Mensuration of the Circle.—The ratio of the length of the circumference to the diameter is the same for all circles. This number can only be calculated approximately, and is 3·141592-65358979323846 as far as 20 places of decimals. The true value of this number is always denoted by π, and has been recognized from antiquity as a most important constant. $\frac{22}{7}$ may be used as a rough approximation to π. Mathematicians have devoted an incredible amount of time to the calculation of this number, even reaching hundreds of decimal places. It is difficult to believe, however, that more than about ten figures could ever be put to any practical use; in fact 3·1415926 is likely to serve well enough. If r is the radius, the length of the whole circumference is $2\pi r$.

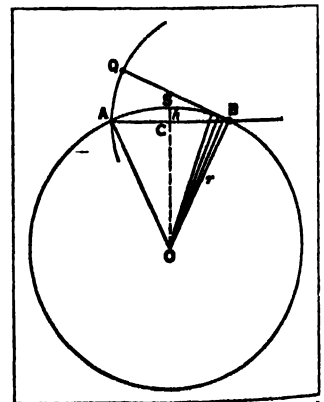

FIG. 4.—DIAGRAM SHOWING A METHOD OF DETERMINING THE AREA OF A CIRCLE

Let s measure the arc AB, c the chord AB, and h the distance from the middle of the arc to the chord. By dividing up the area of the sector AOB as suggested (fig. 4), and reasoning from the sum of a number of small triangles, it is inferred that the *area of the sector* is $\frac{1}{2}rs$; and the area of the whole circle is $\frac{1}{2}r\times 2\pi r=\pi r^2$.

It has long been known that no construction by ruler and compasses can furnish a straight line of length equal to that of the circumference of a given circle, or a square equal in area to a given circle; though in ancient times "squaring the circle" was considered an important unsolved problem. Also a straight line cannot be constructed equal to any given arc of a circle, though approximate methods exist which work well for an arc which is not

too large compared with the radius. For instance, produce *AB* to *P*, making $BP=\frac{1}{2}AB$. With centre *P* and radius *PA* draw an arc cutting at *Q* the tangent at *B*. Then *BQ* = the arc *AB* approximately. For an arc forming a quarter circle the error is about one part in 300. For $\frac{1}{360}$ of the circumference the error is less than one in a million. An approximate relation between *c*, *h* and *s* is $s=c+8h^2/(3c)$. For a value of *h* less than $\frac{1}{12}$ of *c*, this gives *s* to within $\frac{1}{10,000}$ of its value. The radius of the circle does not appear in this relation. As an example of its use, if $c=144$, and $s=144{\cdot}2$, then $h=3{\cdot}3$.

BIBLIOGRAPHY.—Euclid, *Elements*, Bk. III; J. L. Coolidge, *A Treatise on the Circle and the Sphere* (1916); H. S. Hall and F. H. Stevens, *A School Geometry* (1924); D. M. Y. Sommerville, *Analytical Conics* (1924).

CIRCLEVILLE, a city of Ohio, U.S., on the Scioto river, 25 mi. S. of Columbus; the county seat of Pickaway county. It is on federal highways 22 and 23 and is served by the Norfolk and Western and the Pennsylvania railways. The population in 1950 was 8,723. Canned vegetables, straw paper for boxes, advertising novelties, products from corn cobs, stock feeds and soybean meal and oil are among its manufactures. An annual pumpkin show is held. The city was laid out (1806) within a circular embankment of prehistoric origin, with an octagonal courthouse in the centre and circular streets around it. The courthouse was burned in 1841, and no trace remains of the original plan or of the ancient earthworks. The city was chartered in 1853.

CIRCUIT is a path for transmitting electrical energy.

CIRCUIT RIDER, a preacher or minister who supplies several localities, preaching at each in succession and thereby forming a "circuit." Francis Asbury, a follower of John Wesley inaugurated the custom in the United States in Nov. 1771, and for 45 years travelled on horseback, at the rate of 5,000 m. a year, preaching twice a day on weekdays and three times on Sunday. Each circuit was under the supervision of a Wesleyan conference preacher and he might have any number of lay-assistants. Any young man who showed aptness for public speaking and willingness to endure the hardships of travelling in the saddle for weeks at a time over a wild and rough country, might become an assistant and finally a circuit rider. The salary was $64 a year until 1800, when it was raised to $80 a year, with the horse furnished by the circuit. There were almost no meeting houses and services were held in log cabins, bar-rooms or in the open. Circuit riders were a considerable religious and moral force, especially along the frontier.

CIRCUITS, in a legal sense, are the periodical progresses of the judges of the superior courts of common law through the several counties of a given region for the purpose of administering civil and criminal justice. These modern circuits in progresses have taken the place of the *eyres* or *itinera* of the ancient system. The word circuit is also applied to the rotative sittings of judges of county courts in the various towns of the districts over which they preside.

It is provided by s. 70 of the Supreme Court of Judicature (Consolidation) Act, 1925, that judges of the king's bench division of the high court and every judge of the probate division (if the state of business of that division permit) together with such commissioners of assize as may be appointed by letters patent shall be judges of assize. By virtue of their commission all judges and commissioners of assize are entitled within the districts fixed by their commission (including the counties palatine of Lancaster and Durham) to exercise all the powers of civil or criminal jurisdiction capable of being exercised by the high court, including (s. 71) the trial of revenue causes or proceedings. It is further provided by the act (s. 77) that: If at any time it appears to the lord chief justice that there is no business, or no substantial amount of business, to be transacted at the assizes about to be held at any particular place on a circuit, he may, with the concurrence of the lord chancellor, direct that assizes shall not on that occasion be held at such place.

The general regulation of circuits throughout England and Wales, in modern times, was originally provided for by s. 23 of the Judicature Act, 1875 (now replaced by s. 70 of the Supreme Court of Judicature [Consolidation] Act, 1925). By this section power was conferred on the Crown by order in council to make regulations respecting circuits, including the discontinuance of any circuit, and the appointment of the places at which assizes are to be held on any circuit. Under this power, an order in council, dated Feb. 5, 1876, was made reconstructing and remodelling the circuit system throughout England and Wales. By virtue of this order the then existing circuits were discontinued and were replaced by fresh circuits. These, after various mutations, are now settled as follows: the northern, the north-eastern (taken from the northern), the midland, the south-eastern, the Oxford, the western, and the north Wales (with Chester) and south Wales (divisional) circuits. The delimitation of these circuits together with the names of the towns throughout England and Wales at which assizes are held are set out in some 14 orders in council, all of which are printed in *Statutory Rules and Orders*. Birmingham was first constituted a circuit town in the year 1884 and, by arrangement, the work there became the joint property of the midland and Oxford circuits. There are alternative assize towns in the following circuits, viz., on the western circuit, Salisbury and Devizes for Wiltshire and Wells and Taunton for Somerset; on the south-eastern, Ipswich and Bury St. Edmunds for Suffolk; on the north Wales circuit, Welshpool and Newtown for Montgomery; and in the south Wales (division), Cardiff and Swansea for Glamorgan.

The approximate dates for the holding of circuit assizes are: winter (about the middle of January), summer (about the middle of May), and autumn (about the middle of October). Spring assizes for both civil and criminal business are held in April and May in two circuits only, viz., at Manchester and Liverpool on the northern, and at Leeds on the north-eastern. In the past considerable difficulty was experienced in coping with assize work in the provinces and at the same time maintaining the efficiency of the common law sittings in London. With the object of obviating this as far as possible it has been arranged that certain of the common law judges shall remain in London during the whole of the circuits, and the others until their respective commission days which are generally arranged to fall on varying dates.

Counsel are not expected to practise on a circuit other than that to which they have attached themselves, unless they receive a special retainer. They are then said to "go special," and the fee in such a case is 100 guineas for a king's counsel and 50 guineas for a junior. In such cases it is customary to employ in the action one member of the circuit on which the counsel has come special. Certain rules have been drawn up by the bar council for regulating the practice as to retainers on circuit: (1) A special retainer must be given for a particular assize (a circuit retainer will not, however, make it compulsory upon counsel retained to go the circuit, but will give the right to counsel's services should he attend the assize and the case be entered for trial); (2) if the venue is changed to another place on the same circuit, a fresh retainer is not required; (3) if the action is not tried at the assize for which the retainer is given, the retainer must be renewed for every subsequent assize until the action is disposed of, unless a brief has been delivered; (4) a retainer may be given for a future assize, without a retainer for an intervening assize, unless notice of trial is given for such intervening assize. There are also various regulations enforced by the discipline of the circuit bar mess.

In Scotland the judges of the supreme criminal court, or high court of justiciary, form also three separate circuit courts, consisting of two judges each; and the country, with the exception of the Lothians, is divided into corresponding districts, called respectively the northern, western and southern circuits. On the northern circuit, courts are held at Inverness, Perth, Dundee and Aberdeen; on the western, at Glasgow, Stirling and Inveraray; and on the southern, at Dumfries, Jedburgh and Ayr. (W. W.-P.)

UNITED STATES

The United States is organized in 11 judicial circuits (including the District of Columbia as a circuit), a U.S. court of appeals being in each circuit. In the mid-1950s the number of judges on the bench of each court of appeals varied from three to nine. Cases were usually heard, however, in divisions of three judges,

though the judges might sit *en banc* with all present. The chief judge was appointed on the basis of seniority in commission, and one of the U.S. supreme court justices was assigned to each circuit as circuit justice. These courts have appellate jurisdiction over most of the matters determined by the U.S. district courts, but certain matters are taken directly to the supreme court. They are also authorized to review and enforce the orders of various federal administrative agencies.

U.S. Judicial Circuits.—The states and territories of the United States were organized in judicial circuits in the mid-1950s as follows: first, districts of Maine, New Hampshire, Massachusetts, Rhode Island and Puerto Rico; second, districts of Vermont, Connecticut, northern, southern, eastern and western New York; third, districts of New Jersey, eastern, middle, and western Pennsylvania, Delaware and the Virgin Islands; fourth, districts of Maryland, northern and southern West Virginia, eastern and western Virginia, eastern, middle and western North Carolina and eastern and western South Carolina; fifth, northern, southern and middle Georgia, northern and southern Florida, northern, middle and southern Alabama, northern and southern Mississippi, eastern and western Louisiana, northern, southern, eastern and western Texas and Canal Zone; sixth, districts of northern and southern Ohio, eastern and western Michigan, eastern and western Kentucky and eastern, middle and western Tennessee; seventh, districts of northern and southern Indiana, northern, eastern and southern Illinois and eastern and western Wisconsin; eighth, districts of Minnesota, northern and southern Iowa, eastern and western Missouri, eastern and western Arkansas, Nebraska, North Dakota and South Dakota; ninth, districts of northern and southern California, Oregon, Nevada, Montana, eastern and western Washington, Idaho, Arizona and territories of Alaska, Hawaii and Guam; tenth, districts of Colorado, Wyoming, Utah, Kansas, eastern, western and northern Oklahoma and New Mexico; and the judicial circuit of the District of Columbia, with the chief justice of the supreme court as circuit justice.

CIRCUITS, ENGINEERING. There are many ways of classifying the systems designed, analyzed and synthesized by engineers, one of which is to imagine all engineering systems composed of one or more of four basic elements: circuits, processes, energy converters and structures.

A structure may be defined as an engineering system constructed, or existing in nature, to support or retain objects against the effect of the force fields that may be acting upon it or them. Examples are bridges, buildings, highways, dams, transformer cores, etc.

An energy converter is a device which transforms energy from one form to another such as a battery, internal-combustion engine, photoelectric cell, microphone and nuclear reactor.

A process is a progressive action or series of controlled events in the regular course of performing an intended engineering operation such as manufacturing a machine, reduction of an ore, refining of crude oil and production on assembly lines.

A device through which energy, information or matter flows is termed a circuit—the subject of the present article. Examples are an electrical circuit, pipe lines for oil or water, thermal circuits, etc.

Actual engineering systems are usually composed of more than one of the elements, and particular parts of a system may partake of the nature of more than one element. For example, a vacuum tube consists of a structure for supporting the various parts and may also be considered as an energy converter as well as a part of an electrical circuit. It is difficult to classify engineering systems according to these elements; however, the idea of "elements" is most useful in the analysis and synthesis of engineering problems.

The circuit concept has been found very useful for the study of electrical and nonelectrical engineering problems, whether static or dynamic. The employment of the general idea that cause is proportional to effect leads to the following mathematical expression:

$$\text{Cause} = Z\ (\text{effect}). \tag{1}$$

In this expression Z is a proportionality factor, which can oftentimes be interpreted as an opposition. For instance, Ohm's law for a constant continuous direct current may be written as:

$$v = iR. \tag{2}$$

Here the voltage, v, may be considered as the cause for the effect, which is the flow of current, i, against an opposition or resistance, R.

On the other hand, if the current is considered the cause, then:

$$i = v\left(\frac{I}{R}\right). \tag{3}$$

In this instance v is the effect and $\frac{I}{R}$ the opposition.

In some electrical circuits the opposition is made up of a resistance and a reactance. The resistance part opposes the continuous flow of current, and the reactance opposes the change. The total resistance is often termed the impedance.

In electrical engineering the cause was originally designated as being the electromotive force and the current as effect, hence the opposition or impedance was the proportionality factor connecting the cause and effect. Later, in considering electronic circuits, the current was adopted as the cause and the voltage the effect.

The flow of heat through the wall of a building may be analyzed on the basis of a thermal circuit. Here the cause is the difference in temperature between the inner and outer surfaces, while the effect is the heat transfer, the opposition being the thermal resistance and/or thermal capacity of the material. A pipe line through which water flows at a steady rate may be considered a fluid circuit. As an approximation the pressure drop constitutes the cause, the effect is the quantity of water flowing (or a function of this quantity), and the opposition is the frictional effect which opposes the flow of material through the pipe. One might even consider an oversimplified learning circuit as consisting of a teacher (the transmitter) and the student (receiver), connected by an imaginary circuit having an opposition. In this case, the cause would be a stimulus sent by the teacher, the effect the response of the student and the opposition the vocal, auditory and other neural or intellectual blocks and resistances that constitute the impedance of the learning circuit. In this case the response is equal to the ratio of the stimulus to the opposition. For a given stimulus, the greater the opposition of the learning circuit, the smaller would be the response. If one wished to portray the actual learning circuit, it would be necessary to establish a very complicated network consisting of many other factors such as feedback.

Feedback, or the process of transferring energy or information from the output of a circuit to its input, is a very important concept in complex circuit analysis and synthesis. Control by feedback plays a dominant part in industry and everyday life. Feedback control is an operation which reduces the difference between the actual state or condition of a system and an arbitrarily desired state or condition in response to the detected difference between them. In order to illustrate a simple feedback control system, consider a bimetallic thermostat and related circuits for the control of a home gas furnace. The desired temperature is set by adjusting the dial on the thermostat. This control unit then detects or senses any differences between the actual and desired temperatures. The difference is also termed an error. If an error or difference exists, a pair of contacts in the thermostat closes or opens the circuit, thereby initiating the desired action. If the house is too warm, the feedback control shuts off the furnace, and if the temperature falls below the desired value the furnace is turned on. Changes in temperature, which are classed as disturbances as far as the control system is concerned, result from changes in the atmospheric conditions. The control of body temperature in human beings is an excellent example of feedback control. This amazing body temperature regulation is accomplished in a feedback control system which is based in part on a balance of the heat losses through conduction, convection, radiation and evaporation of water and energy gains by metabolism and the muscle action.

In the analysis and synthesis of engineering circuits, it becomes apparent that to produce an effect there must be a cause. The cause, effect and opposition are related in such a manner that the cause is proportional to the effect. In order to illustrate this relationship for a mechanical system, imagine a block of wood sliding down a steep, inclined plane in such a manner that the velocity of

the block increases with the distance travelled. The cause which accounts for the movement of the block is the resultant of the downward gravitational force component and the backward frictional force between the block and the plane. The effect is manifest as an acceleration of the block, and the opposition is represented by the mass of the block. Hence the net driving force or cause equals the product of the acceleration and the mass of the block. This is immediately recognized as one of Newton's laws of motion.

In engineering circuits, the cause variable is often referred to as a driving potential. Hence the cause variables for several circuits are: for a thermal circuit, the temperature difference; for a fluid circuit, the pressure difference; and for an electrical circuit, the voltage or current. All engineering circuits show some form of opposition; otherwise a finite cause could produce enormous effects, which is contrary to experience.

FIG. 1.—PLANER ONE LOOP *LRS* NETWORK (*see* TEXT FOR FURTHER EXPLANATION)

For convenience, the opposition variable may be divided theoretically into two classes: one in which energy is converted into another form, the other in which energy is stored. Mechanical friction would serve as an example of opposition wherein energy is converted. An electric capacitor is a unit in a circuit where potential electrical energy is stored.

A circuit is usually composed of a number of units joined together by connectors. The effect variable is the same at any given time throughout the unit, while the cause variable varies across the unit. For convenience the symbols C, E and Z will be employed to designate the cause, effect and opposition quantities.

According to the general relation it may be stated that the opposition is equal to the ratio of the cause to the effect variable, or

$$Z = C/E.$$

The product of the cause and effect variable often represents apparent power. For example, in an electric circuit the power term may be expressed as the product of voltage and current.

According to the laws of conservation of mass and energy, neither can be created nor destroyed. From these laws, two very important propositions result. The first is that the summation of the effect variables about a point in a circuit must be equal to zero. Also, it may be concluded that for a closed circuit the summation of the cause variables across the individual units must be equal to zero.

When applied to an electrical circuit, these two are recognized as the potential and current laws established by Gustav Robert Kirchhoff in 1857. The Kirchhoff potential law states that the vector sum of the potential differences across the individual unit in any closed path in an electrical network is equal to zero. The current law states that the vector sum of the current flowing at a node in a network is zero. By vector sum is meant the resultant effect of several separate effects; for example, the vector sum of the differently directed forces in the guy wires attached to the top of a television mast at a given instant in a windstorm is the single force in a single imaginary wire that would have the same effect as all the separate wires do have at that time. A node in this case is the junction of the several elements.

Before the use of circuits in the solution of engineering problems is discussed, consideration will be given to certain aspects of the elements of electrical networks.

Resistance and conductance are the elements in an electrical circuit which determine for a given current the rate of conversion of electrical energy to heat. According to the general relation previously discussed for a given instantaneous voltage v (cause variable), and current i (effect variable), the following expression may be written for the resistance R (opposition):

$$v = iR, \tag{2}$$

or if, as explained above, i is to be taken as the cause variable, then

$$i = \frac{v}{R} = Gv. \tag{3}$$

In order to avoid the use of the resistance in the denominator, the symbol G is used to replace the reciprocal of the resistance and is called the conductance.

Inductance is the property of a unit in an electric circuit or of two neighbouring circuits which determines the electromotive force induced in one circuit as a result of a change in current in either of the circuits. An expression for the opposition potential for an inductance follows:

$$v = L\frac{di}{dt}. \tag{4}$$

In this expression, it is seen that the voltage, v, is equal to the product of the inductance, L, and the rate of change of the current. Solving this relation for di gives:

$$di = \frac{v}{L}dt, \text{ and so}$$
$$\int di = i = \frac{1}{L}\int v\,dt = \Gamma \int v\,dt. \tag{5}$$

To avoid the use of the reciprocal of the inductance, the symbol Γ has been introduced and is called the inverse self-inductance.

An element in which electrical potential energy is stored is called a capacitor. The voltage drop v across a capacitor may be expressed as follows:

$$v = S\int i\,dt. \tag{6}$$

In the expression S is called the elastance. The corresponding value of di is $Sidt$. So

$$i = \frac{1}{S}\frac{dv}{dt} = C\frac{dv}{dt}. \tag{7}$$

In order to avoid the use of the reciprocal of elastance, the symbol C, called the capacitance, is introduced.

Attention will now be directed to a planer one loop network consisting of a voltage source, v; inductance, L; resistance, R; capacitor, S; and switch as shown in fig. 1.

The summation of the effect variable (voltage drop) for the various units of the closed circuit is zero, or

$$v = v_L + v_R + v_S. \tag{8}$$

Replacing the voltage values by their equivalents gives:

$$v = L\frac{di}{dt} + Ri + S\int i\,dt. \tag{9}$$

This is a differential equation expressing the relationship of voltage and current as functions of time. The time is measured from the instant when the switch is closed.

Consider next the planer one node pair $CG\Gamma$ network shown in fig. 2. The opening of the switch at time zero allows current to flow through the various units. Since the summation of the effect variables at a node is zero, the following current equation may be written:

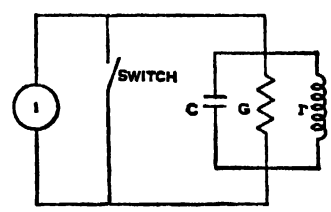

FIG. 2.—PLANER ONE NODE PAIR $CG\Gamma$ NETWORK (*see* TEXT FOR FURTHER EXPLANATION)

$$i = i_C + i_G + i_\Gamma. \tag{10}$$

Replacing the various terms by their equivalents results in the following differential equation:

$$i = C\frac{dv}{dt} + Gv + \Gamma\int v\,dt. \tag{11}$$

Comparing the differential equations (9) and (11) indicates that the mathematical forms are the same. In other words, the two networks constitute two different physical representations of the same general equations. Two networks of this type are called analogous, and one network is often referred to as the dual of the

other. This concept of duality of circuits is extremely important in the analysis of other circuits by electrical means (*see* Table I).

TABLE I.—*Variables and the Corresponding Duals for Electrical Circuits*

Element or variable	Dual of element or variable	Element or variable	Dual of element or variable
Voltage, v	Current, i	Resistance, R	Conductance, G
Inductance, L	Inverse inductance, Γ	Elastance, S	Capacitance, C

Mechanical Electrical Analogies.—In order to show the application of the electrical circuits to the study of the vibration characteristics of a mechanical system, consider the system shown in fig. 3. The sketch illustrates schematically a mass, M, supported by a spring, K, and a mechanism such as a dashpot to retard the vibrations caused by a force, F. The general differential equation for the force, F, may be expressed as follows:

$$F = M\frac{dv}{dt} + Dv + K\int v dt. \qquad (12)$$

By crossing out the last two terms on the right side of this equation one obtains one of the well-known equations of motion of Newton which states that force is proportional to the product of the mass and acceleration. The retarding force of the dashpot is assumed to be equal to a constant D multiplied by the velocity v. The spring force is equal to the product of the spring constant K and the integral indicated. The two additive forces have been allowed for in the equation as stated.

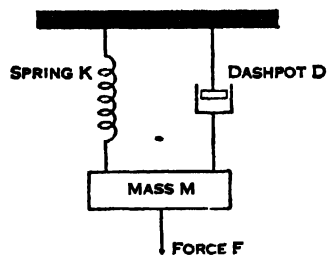

FIG. 3.—SCHEMATIC DRAWING OF A MECHANICAL SYSTEM

Comparing equation (12) with relations (9) and (11) for the two electrical circuits reveals the analogy between the differential equations for the mechanical and electrical systems. These equations are, in fact, identical in form. By the proper choice of physical constants for one circuit, corresponding constants that appear in the analogous circuits can be made strictly proportional one to the other. It is, therefore, possible to determine the behaviour of a mechanical system by the study of an equivalent electrical circuit. Since it is often much more convenient to measure current and voltage than force and velocity, this type of analysis is extremely useful.

Comparison of the terms in these three equations results in Table II of analogous quantities between a mechanical system and two types of electrical circuits.

TABLE II.—*Analogous Quantities*

Mechanical system	Electrical force analogous to voltage	Circuits force analogous to current
Force, F	Voltage, v	Current, i
Mass, M	Inductance, L	Capacitance, C
Dashpot constant, D	Resistance, R	Conductance, G
Spring constant, K	Elastance, S	Inverse inductance, Γ

By use of these analogies, it is possible to establish equivalent electrical circuits for use in the study of many mechanical systems.

Equivalent electrical circuits have been employed to study many engineering problems, a few of which are: the motion and stresses in the parts of a vacuum tube when it and its cardboard container are dropped to the floor, the motion of the wheels and body of an automobile as it strikes a bump in the road, design of crankshafts and study of vibration and stresses in existing units.

Thermal-Electrical Analogies.—Resistance-capacitance electrical circuits may be used for the study of complex heat transfer problems by establishing suitable analogies. In this analogy, electric current corresponds to heat flow in the thermal circuit, voltage to temperature difference, electrical resistance to thermal resistance and electrical capacity to thermal capacity.

The equivalent electrical circuit which is constructed to portray the thermal circuit is made up of "lumped" resistances and capacitances. The lumping corresponds mathematically to the replacement of a differential equation by an equation of finite difference. The word "lumping" is used to convey the idea that a property such as capacitance or resistance which may be distributed along a unit (say along its length) in the one circuit is concentrated at a point in the corresponding unit of the analogous circuit. The lumping of the resistances and capacitances may be briefly described by saying that a physical body is considered as being divided into a number of geometrical sections of simple shape and form. Resistance to heat flow in a section is represented by resistors emanating from the meeting at the centre of the section. The thermal capacity of a section is considered to be concentrated at the geometrical centre of the section. Using this procedure, a body under investigation may be replaced by a lumped resistance-capacitance electric network. Heat sources and boundary conditions may also be replaced by their electrical equivalents.

The analogy between heat flow in a thermal circuit and the passage of current in an electric conductor is based upon the comparison of the basic partial differential equation for the temperature distribution in a solid and the partial differential equation for electric potential in a noninductive conductor, and the rate at which thermal energy is stored and the rate of flow of charge in a capacitor.

In order actually to establish the magnitude of the units in the equivalent electrical circuit, it is necessary to obtain a set of ratios corresponding to thermal and electrical properties. For example, the potential ratio is defined as the unit of potential in the thermal circuit to the unit of potential in the electrical circuit. The seven ratios normally used are: potential, flow, resistance, quantity, time, capacity and distance or position ratio. By suitable algebraic manipulation, basic relations for the various ratios may be established. These relations are expressible in terms of three independent ratios or variables. However, in practice the arbitrariness of their choice may be restricted by the electrical components. For example, to minimize the leakage from the electrical capacitors, a "speed-up" in the electrical circuit is desirable; however, such a choice may call for some electrical resistances in the circuit greater than any available. In addition, certain heat transfer problems may possess unusual heat input conditions, which will influence the choice of the independent ratios.

Equivalent electrical circuits have been used extensively in the study of many thermal circuits, a few of which may be mentioned. heat flow from fins, temperature distribution in cooled turbine blades, deicing studies dealing with aircraft wings and propellers, temperature distribution in gas turbine disks and the design of heat exchangers.

Complex heat flow problems may be studied by an analogy consisting of a vessel filled with a conducting fluid. Studies have been made to determine the heat flow through corners of complex furnace walls by this analogy. The inside and outside surfaces of a thick corner section were represented by metal corners forming the vertical walls of a tank. Beyond the corner for each wall boundary partitions were installed, which were made from nonconducting material. The bottom of the tank was constructed from a nonconducting material. The tank was filled with a conducting liquid which was analogous to the homogenous material of the wall section. An electrical potential was established between the outer parallel conducting surfaces; thus the analogy between steady heat flow conditions between constant temperature walls was established. By means of an electrical probe, the isopotential (or equipotential) lines were obtained, which represent the isothermal lines (or lines of equal temperature) in the thermal system. This may be classed as a geometrical thermal electrical circuit analogy. This type of analogy has been used in the solution of many engineering problems, some of which are: effect of thermocouple holes in the measurement of temperatures of thick castings during quenching operations, establishment of pressure gradients on the faces of irregular-shaped dams and heat-flow problems involving variation of thermophysical properties with temperature.

An analysis similar to the conducting liquid tank procedure has been used for which the liquid bath is replaced by a solid conductor of uniform electrical characteristics. The conductor consists of a

thin metal sheet out of which the particular geometrical shape is cut. Using the electrodes at the boundary edges, isopotential lines can be obtained by use of a probe. This type of analogy has the advantage of simplicity in obtaining the direct geometrical patterns desired. It has been used successfully for the design of insulated walls in cold-storage rooms.

Another useful analogy is the hydraulic thermal circuit, which has been used in the study of heat exchange apparatus. One such apparatus consisted of vertical glass tubes connected by means of capillaries. A liquid such as water flows through the capillaries, and the change in level with time in the glass tubes is measured. Time and liquid level in the fluid circuit correspond to time and temperature in the heat exchanger. Heat losses to the surroundings, variable specific heat and change in phase may be taken into account by means of the analogy.

Many other types of analogues have been used for the analysis and synthesis of engineering systems.

A physical system and its circuit analogue may both be regarded as (physical) analogues of an abstract system whose behaviour is defined by a mathematical formulation such as a differential equation. It may be stated that the circuit analogue solves approximately the mathematical problem defined by an (abstract) system and consequently solves that of the given physical system. In this respect the circuit analogue may be called a computer. It is commonly called an analogue computer not only because it measures one type of physical quantity in terms of another but because it measures the numerically defined variables of the abstract system in terms of some physical system. A natural limit of the precision of evaluation of the numerical variables is induced by the dependence on physical measurements. A thermal analyzer, because it solves heat transfer problems electrically, and an electronic differential analyzer, because it solves differential equations by simulation through circuits, are examples of analogue computers. The former is an example of a direct analogue computer while the latter is one of the indirect types.

The direct analogues may be subdivided into mechanical, fluid and electrical types. For example, direct strain measurements may be made on plastic models of engineering structures to study deflections and stresses. The fluid class covers such devices as models of dams and river beds which are found in many hydraulic laboratories. These models are used for various studies including flood control, drainage and erosion problems. The electrical devices are those which use the analogy between electrical circuits and others; for example, as previously shown, the direct electrical analogy between a simple mechanical spring and the energy storage in an electrical capacitor. The use of the principle of duality is often employed so as to have the computer operate on the dual of the problem. Such devices as the alternating current network analyzer used for the study of electric power distribution systems, and the thermal analyzers used for the study of complex thermal circuits, are examples of the direct electrical analogue.

The indirect analogues may be subdivided into mechanical and electrical indirect analogue computers. Examples of the mechanical type are: the slide rule where lengths measured on a rule are indirectly analogous to numbers, nomograms, the Norden bomb sight and the general-purpose differential analyzer which Vannevar Bush and others designed and constructed. The electrical indirect analogue computer is a very common type which employs such devices as high gain amplifiers, feedback loops, etc. Many of the gun directors are in this class of computers.

A special-purpose computer is one that is functionally limited to the description of restricted types of systems; for example, those defined by simple differential equations. Often the analogous circuit requires extensive physical modification whenever the parameters of physical systems change. A more versatile device is the general-purpose computer, which is designed to solve any abstract mathematical problem directly without requiring physical modification. Hence the same computer may be used to evaluate two vastly different systems such as the flow of heat in a cylinder and the determination of an optimum inventory pattern for a warehouse.

General-purpose computers treat all quantities in digital form, and their precision is quite superior to that of the analogue computers. Devices of this type are becoming commoner as research tools because of their flexibility and speed.

CIRCULAR NOTE, a documentary request by a bank to its foreign correspondents to pay a specified sum of money to a named person. The person in whose favour a circular note is issued is furnished with a letter (containing the signature of an official of the bank and the person named) called a letter of indication, which is usually referred to in the circular note and must be produced on presentation of the note. Circular notes are generally issued against a payment of cash to the amount of the notes, but the notes need not necessarily be cashed, but may be returned to the banker in exchange for the amount for which they were originally issued. A forged signature on a circular note conveys no right, and as it is the duty of the payer to see that payment is made to the proper person, he cannot recover the amount of a forged note from the banker who issued the note. (*See* also LETTER OR BILL OF CREDIT.)

CIRCULARS AND CIRCULARIZING, a means of advertising and selling which reached large proportions as a result of rapid printing and postal extension in the 20th century. This consists of descriptive circulars and other forms of advertising literature sent through the mails to bring about sales directly to possible customers. It has long been widely used in France and the United States, in connection with catalogues mailed on request by department stores, seedsmen and manufacturers of various articles than can be economically shipped.

With the development of the mail-order houses, particularly in the United States, the use of this method of advertising greatly extended. Catalogues of 1,000 pages or more sometimes are sent broadcast to urban and farm dwellers alike, who give orders for clothing, pianos, agricultural implements, household utensils and a great variety of other articles. The number of mail-order houses in the United States is estimated at 125, with yearly sales approximating $500,000,000. With the extension of the parcel post and favourable postal rates, this form of advertising was widely adopted by manufacturers. (W. S. Hi.)

CIRCULATING MEDIUM: *see* MONEY.

CIRCULUS IN PROBANDO, in logic, a phrase used to describe a form of argument in which the very fact which one seeks to demonstrate is used as a premise; *i.e.*, as part of the evidence on which the conclusion is based. This argument is one form of the fallacy known as *petitio principii*, "begging the question." It is most common in lengthy arguments, the complicated character of which enables the speaker to make his hearers forget the data from which he began. The following duologue may serve as a simple illustration of circular argument. "He speaks with angels," said one of the Master's disciples. "How know you that?" I asked. "He himself admits it," he replied solemnly. "But suppose he lies?" I persisted. "What!" he exclaimed, "a man who speaks with angels capable of telling a lie?"

(*See* FALLACY.)

CIRCUMCISION. From a medical as distinguished from a ritual aspect this simple operation consists in removal of a sufficient portion of the foreskin to allow of its free retraction beyond the glans penis. The operation is performed chiefly for purposes of cleanliness and to facilitate removal of the smegma which

normally collects beneath the foreskin but sometimes is necessary to allow free passage of urine. For these purposes it is done as a preventive measure in the infant. In adults the chief reason for its performance is balanitis or inflammation beneath the foreskin resulting from lack of cleanliness or from the presence of a venereal sore; in this case circumcision is a necessary part of the treatment. It is noteworthy that in India the Hindus, who do not circumcise ritually, suffer far more frequently from cancer of the penis than the Mohammedans, who circumcise. Circumcision is also an initiation or religious ceremony among Jews and Mohammedans and is a widespread institution among many Semitic peoples. It remains, with Jews, a necessary preliminary to the admission of proselytes. Its origin among them is placed in the age of Abraham (Genesis xvii), and at all events it must have been very ancient, for flint stones were used in the operation. The significance of the rite has been much disputed, including views that it was a tribal badge, a substitute for sacrifice and an act of cleanliness. Most probably, it was connected with marriage. (*See* MUTILATIONS AND DEFORMATIONS.)

CIRCUMNAVIGATION OF THE WORLD. Although the efforts to find a route to the Indies had already led to the great voyages of Columbus, the Cabots, Bartholomeu Diaz de Novaes and Vasco da Gama, to Ferdinand Magellan was due the honour of having first sailed round the world (1519–22), although he himself died on the way. The first British circumnavigator was Sir Francis Drake (1577–80), who was followed by others, English, French and Dutch, in the next two centuries, until the celebrated three voyages of Capt. James Cook in 1768–70, 1772–75 and 1776–79 practically completed the discovery of the main outlines of the known world. (*See* individual biographies and the articles GEOGRAPHY and MAP.)

CIRCUMSTANTIAL EVIDENCE is a kind of indirect evidence. Suppose something happens in the presence of witnesses who observe it, then their evidence is *direct* evidence of the occurrence. But now suppose there is no such direct evidence of the event, then it is necessary to rely on indirect evidence, if any. Such indirect evidence usually consists of certain circumstances surrounding the event or in some way connected with it. By piecing these circumstances together we may get an intelligible, coherent account of the whole course of the event or events in question. This piecing together of the data is a kind of hypothesis, and there may be several rival hypotheses to account for the facts. But as in all cases of the use of hypotheses, the hypothesis which gives the most adequate and consistent explanation is usually accepted. Inference from circumstantial evidence resembles ordinary induction to the extent that it involves the use of hypotheses and their verification, but it is unlike ordinary induction inasmuch as it does not aim at a generalization, being concerned only with some particular event. The systematic character of inference is perhaps most obvious in the case of inference from circumstantial evidence, for it manifests most clearly the process of the imaginative construction of a coherent system out of fragmentary evidence. The most familiar occasions for the exercise of inference from circumstantial evidence are criminal cases. Criminals naturally take precautions against the possibility of direct evidence, and are usually betrayed by circumstantial evidence. (*See* EVIDENCE.)

See A. Wolf, *Essentials of Logic* (1926).

CIRCUMVALLATION, LINES OF, in fortification, a continuous circle of entrenchments surrounding a besieged place, facing outward, by which the besieger protected himself against the attack of a relieving army from any quarter (from Lat. *circum*, round, and *vallum*, a rampart). "Lines of contravallation" were similar works but naturally of less circumference, facing inward, as a resistance against the sorties of the besieged.

CIRCUS. In Roman times the circus was a space or building intended for the exhibition of races and athletic contests held at public festivals. In spite of the connection of the Latin *circus* with the Greek *κίρκος* or *κρίκος*, a ring or circle, the arena was not circular; it was a rectangle with one semicircular end. Down the centre of the arena ran a fence (*spina*), separating the outward course from the return, and at each end were three conical pillars (*metae*) to mark the limits of the course. On the *spina* were obelisks, images and ornamental shrines; and, in addition, seven figures of dolphins and seven oval objects, one of which was taken down at each of the seven rounds made in a chariot race. Tiers of seats ran parallel to the sides of the course and its semicircular end, the straight end being occupied by the stalls (*carceres*), where the horses and chariots were held. The lower seats were reserved for persons of rank, and there were also various state boxes; *e.g.*, for the giver of the games and his friends (called *cubicula* or *suggestus*). The circus was the only public spectacle at which men and women were not separated. The competitors wore different colours, originally white and red to which green and blue were added. Domitian introduced two more colours, purple and gold, which probably fell into disuse after his death. To provide the horses and large staff of attendants it was necessary to apply to rich capitalists and owners of studs, and from this there grew up in time four companies (*factiones*) of circus purveyors, which were identified with the four colours, and with which those who organized the races contracted for the horses and men. (*See* also GAMES.) The drivers, who were mostly slaves, were sometimes held in high repute for their skill. The horses most valued were those of Sicily, Spain and Cappadocia, and great care was taken in training them. Chariots with two horses or four were most common, but sometimes also they had three and exceptionally more than four horses. Occasionally there was combined with the chariots a race of riders, each rider having two horses and leaping from one to the other during the race. At certain of the races the proceedings were opened by a procession in which images of the gods and of the imperial family deified were conveyed in cars drawn by horses, mules or elephants, attended by the colleges of priests and led by the presiding magistrate (in some cases by the emperor himself) seated in a chariot in the dress and with the insignia of a *triumphator*.

In addition to the races, animals were occasionally massacred as an incidental amusement, but the proper place for bloodshed was the sand of the amphitheatres, such as the Colosseum, which were built round an oval arena. Shows of this kind included an emperor's display of archery, as well as gladiators, fights between men and beasts, merciless pugilism and wrestling, and those representations of mythological horrors, with prisoners to reenact the sufferings of ancient heroes, which Martial describes. It may be noted that "amphitheatre" came into the English language as the name for a prize fighters' hall, and "circus" for the circular road in Hyde Park used by the so-called chariots of the 17th century.

The oldest circus in Rome was the Circus Maximus, in the valley between the Palatine and Aventine hills where, before the erection of any permanent structure, races appear to have been held beside the altar of the god Consus. The first building was by tradition assigned to Tarquinius Priscus (616–578 B.C.). But it was under the empire that the circus first became a conspicuous public resort. Caesar enlarged it to some extent, and also made a canal ten feet broad between the lowest tier of seats (*podium*) and the course, as a precaution for the spectators' safety when exhibitions of fighting with wild beasts, such as were afterward confined to the amphitheatre, took place. When these exhibitions were removed Nero had the canal filled up.

Next in importance to the Circus Maximus in Rome was the Circus Flaminius, erected 221 B.C. in the censorship of C. Flaminius, from whom it may have taken its name; the name may, however, have been derived from Prata Flaminia, where the circus was situated.

A third circus in Rome was erected by Caligula and was known as the Circus Neronis, from the notoriety which it obtained under Nero. A fourth was constructed by Maxentius (4th century A.D.) outside the Porta Appia near the tomb of Caecilius Metellus, where its ruins are still, the only instance from which an idea of the ancient circuses in Rome can be obtained. Old topographers speak of the six circuses, but two of these appear to be imaginary, the Circus Florae and the Circus Sallustii.

THE MODERN CIRCUS

There is no resemblance at all between the ancient and the modern circus. The modern circus, at its simplest, may mean a circular space occupied by a pony and a clown; usually the arena serves for acrobats, jugglers, lion tamers, sea lions, horsemen, trick riders and "liberty horses," with apparatus overhead for trapezists and funambulists; or there may be three such arenas and two square platforms inside a "hippodrome track" for processions and races. The performances, surrounded by hundreds or thousands of seats, are either in tents or in structures ranging from the largest exhibition halls to the permanent circus buildings of Paris, Berlin, Moscow, Budapest and Blackpool.

What might be termed horseless circuses in the modern sense of the term existed for many centuries. Records of travelling companies who performed a feat of balance called the "force of Hercules" (more

familiarly the "pyramids") prove such troupes to be a genuine link between the old and the new. They were seen by Claudian in Rome, by Sir Philip Sidney in Brabant, by Joseph Addison in Venice and by Goethe in the Rhineland.

Early Development.—If these troupes can be accepted as the direct line of descent, then the oldest circus family is that founded in Germany by Johann Eberhard Renz, an itinerant acrobat who died on Jan. 31, 1708, and bequeathed his trade to several generations. Trick riders were also recorded by famous spectators, from Homer to Montaigne. Midway through the 18th century numbers of them turned showmen because of the lack of employment in the homes of the nobility. Jacob Bates attracted attention on the continent with feats that are shown on a large engraving. As his fame spread from 1760 onward, former dragoons of the English regiments in the Prussian service took to his way of life. Several appeared at the pleasure resorts of Islington where Sgt. Maj. Philip Astley (1742–1814) began his new career before he settled down just south of Westminster bridge, with his wife as partner to ride and beat the drum, and later their son John as an addition to the growing company. On that site, to be known as Astley's for more than a century, he combined horsemanship and acrobatics with clowning in the way that has won for him the title of "the father of the circus." Yet it was not he who gave it its name, but Charles Hughes, a deserter from his company, who set up his riding school at the other end of Westminster Bridge road. Each added a stage to his arena, Royal Amphitheatre of Arts becoming the name of Astley's and Royal Circus of Hughes's—but with so little inkling of what was in store that "Circusiana," the printed collection of its melodramas, mentions only one horse.

While Hughes introduced the new type of entertainment to Russia, Astley built amphitheatres in many English cities and also in Dublin. He owned another in Paris until the Revolution, when it came under the control of Antoine Franconi (1738–1836) whose influence was so decisive that the ring everywhere would keep to his measurement—13 m. diameter—and showmen would long continue to live, like him, in a caravan.

The 19th Century.—Neither Franconi nor Astley rested content with trick riders, clowns and performing animals; both used stage and arena combined for spectacles which developed into the equestrian drama. In 1806 John Astley represented Mungo Park's travels with "camels and real horses," and in 1810 introduced cavalry charges into "The Blood Red Knight," by J. H. Amherst, which won an unprecedented success. Under Andrew Ducrow (1793–1842), who began with Amherst's "The Battle of Waterloo" in 1824, Astley's amphitheatre enjoyed such favour that its mark has been left on Victorian literature, notably *The Old Curiosity Shop, The Newcomes, The Ingoldsby Legends* and *The Bon Gaultier Ballads*. Napoleonic spectacles at Franconi's in Paris inspired Heinrich Heine's moving account of the old guardsman who had been to see the circus version of Austerlitz, and no biped play of the 19th century equalled the popularity of H. M. Milner's "Mazeppa," as arranged for horses by Ducrow in 1831.

Shakespeare on horseback, opera on horseback and representations of the Crimean War were tried by William Cooke while manager of Astley's, but these were only a minor event in the history of the largest of all circus families. Thomas Taplin Cooke (1782–1866) had 19 children; they and their children linked themselves by marriage with circuses in all parts of the world. Their closest rivals in Great Britain midway through the 19th century were the Battys, Ginnetts and Fossetts; the Sangers came to the front in 1871 when they bought Astley's. *Seventy Years a Showman*, the autobiography of "Lord" George Sanger (1827–1911), describes his unfailing enterprise in making the public "walk up," more especially when he caused his own procession to cross London closely behind a column of troops escorting Queen Victoria. When "Sanger's, late Astley's" was demolished in 1893 he still asserted his supremacy; he was responsible for the "Congress of All Nations" before it was bought by P. T. Barnum, for Christmas pantomimes which contained lions, tigers, zebras, elephants and horses, for mimic wars in China and the Sudan complete with gunboats that had hoofs showing below their waterlines, and for glittering parades in which cavalcades, bands and menageries preceded towering triumphal cars, called tableaus, of gleaming gold.

Voyaging companies soon had to face local competition for South Africa was provided with circuses of its own by Frank Fillis, the Pagels and the Boswells, while in Australia the Wirths not only triumphed on their own ground but took ship for Africa, South America and England.

While there was a strong resemblance between all these shows of the English-speaking world, Paris developed a style of its own. At the Cirque d'Hiver and the Cirque d'Été (later the Théâtre Marigny), descendants of Antoine Franconi appealed to the world of fashion. Even ballerina and prima donna found close rivals in the top-hatted, wasp-waisted *écuyères* who demonstrated their exquisite skill *en haute école* in a dare-devil style that sometimes proved fatal. Impressionist painters, notably Georges Seurat and Henri de Toulouse-Lautrec, preferred the Médrano in Montmartre, where *clownesse* and *acrobate* were the stars.

Spain had few large circuses of its own apart from the one established in Madrid, and delight in this form of entertainment has regularly favoured travelling shows from abroad, more particularly those from France. "Circo" often means variety under canvas.

In Germany the first showman to become well known throughout the world was Ernst Renz (1814–92), the son of acrobats. Scottish rope walkers brought him up, but it was as a horse trainer that he joined the Brilloff circus which he directed until he founded a one-horse circus of his own with Gotthold Schumann as his partner. In the 1860s the Circus Renz was the most elaborate in existence; it failed under Ernst's son, Franz, and revived under Franz's cousin, Robert, whose wife, Oceana, was said to be the loveliest woman ever to perform in the ring. Busch is the name of more than one circus family on the continent: Paul Busch was responsible for the stone amphitheatre in Berlin which bears their name. But it was the Schumanns who made their influence felt in most capitals. Gotthold's son, Albert (1858–1939), started his training at the age of three and lived to be called (by Sir Charles Cochran) "the outstanding horse trainer of our time." In 1885 he opened a little circus at Malmö in Sweden which steadily grew in size on its European tours until it took over the Berlin headquarters of Renz (which as the Circus Schumann made theatrical history under Max Reinhardt). Max, Albert's brother, managed an American circus on tour in India where he married Victoria Cole, the English rider, who bore Willie in the East Indies, Ernest in India and Oscar in Petrograd. Twelve years of absence cost him his German nationality but by buying a house and land in Sweden he acquired Swedish. In 1914 his company was at Berne. The tent poles had barely been raised when telegrams arrived from different countries, calling men to the colours. The staff of 150 included Austrians, Englishmen, Frenchmen, Germans, Russians and Italians. Without a sign of ill-feeling they left, group by group, while the performance was being given before five people. The Schumanns were stranded and had to sell their horses, but after two years in Switzerland they recruited a company of Swedes and Danes and travelled to Copenhagen, which became their headquarters.

The 1920s and After.—During the 1920s there was an astonishing revival of the circus throughout Europe, in which the Schumanns played a leading part as horsemen. Where such animals as lions, tigers, bears and sea lions, besides at least one sea elephant, were concerned, the Hagenbecks rivalled them closely. Gottfried Hagenbeck, a fishmonger of Hamburg, began by exhibiting seals in his back yard. His son, Carl, who founded the family circus in 1887, installed the zoo at Stellingen which showed how cages could be abolished. The custom of regularly including circuses among London's Christmas entertainments began when the Ringlings thought of coming from America at that time; when they changed their minds Bertram Mills put on a show at Olympia in their place. When all due credit has been paid to his remarkable sense of showmanship, it must be recognized that the 1920s witnessed a veritable harvest of performing prodigies. Besides the Schumanns and the Hagenbecks, he drew on the talents of the Sangers and the Wirths. From France he brought riders of the historic Rancy family to display that legendary act of riding and tooling eight horses at once, called "Les Relais de Longjameau" though Ducrow invented it as "The Courier of St. Petersburg." Fully to explain how exceptional those years between the wars were, a detailed account would have to be given of the juggling of Enrico Rastelli, the somersaults on the slack wire of Con Colleano and the feats of Alfred Codona, the trapezist, and his wife, Lilian Leitzel, who swung herself round and round scores of times while hanging by one hand until one night in Copenhagen the apparatus broke and she was killed. For humour at Olympia there were Charlie Rivel on the parallel bars in the garb of Charlie Chaplin and the water-spilling variations of the Bronetts, leading up to the climax when the Schumanns packed the ring with troupe after troupe of liberty horses. Rival Christmas shows were given at the Agricultural hall where Alfred Court, the most daring of all *dompteurs*, came one year from France with his lions, tigers, bears, panthers and jaguars in a cage together.

When the Nouveau Cirque, once the haunt of those memorable clowns, the Yorkshire Foottit and the Negro Chocolat, was pulled down, and when the large Cirque de Paris vanished also, it seemed that Paris might be growing lukewarm, but the Fratellini, who might be called a dynasty of clowns, excited admiration and affection, first at the D'Hiver and then at the Médrano. German circuses prospered particularly while tenting for they visited towns starved of fun because too poor to make a music hall pay; in addition to many small or medium-sized shows there were two or three of the American size. Karl Krone, who came to Berlin in triumph in 1925, used three rings and two platforms. "The good Gleich," as E. V. Lucas called him, packed two (later three) rings with displays of 200 horses and 14 elephants. Hans Stosch-Sarrasani used one ring but concentrated more colour and movement into the space than had ever been known before and surrounded it with seats for 10,000 people. "Unprecedented" was the aim everywhere. Alfred Schneider tamed 75 lions and with them topped the bill at Olympia.

The effects of World War II on the circus were curious. In 1940 the difficulties were so great that those plucky showmen the Rosaires had a hard fight to survive. Then came a boom enjoyed by fifty circuses; afterward the leading place was taken by Chipperfield's, one of the oldest. In Germany Krone was succeeded after his death by his daughter, Frieda, who herself trained elephants. The Hagenbecks still tented, but the most prominent name was that of Althoff, also a very old circus family, who possessed two or three circuses of their own and were represented by relations in the tents of many others. Every-

where in the 1950s the public welcomed the show and in London there were rings each Christmas at Olympia, Earl's Court and Harringay; but the skill displayed rarely reached the high standards set by the astonishing 1920s.

UNITED STATES

The American circus is a spectacular form of entertainment, nomadic in character, presenting its exhibitions in tents (rarely in buildings) and moving its performers, staff, working crew, animals and all paraphernalia on its own railway cars; or, in the case of a few small shows, by horse-drawn wagons, motor trucks or river boats. It comprises, physically, in the order met with from the approach (front); refreshment booths (candy stands); ticket and office wagons; one or more side shows (kid shows) containing human and animal oddities; the big show main entrance (front door); the canopied way (marquee) leading to the menagerie; the menagerie tent exhibiting animals caged and in corrals; the elephant line-up and refreshment stands; the canvas-walled passage (connection) leading from the menagerie to the main-tent (big top); the rear entrance (back door) to the main tent, opening on a compound (back yard) in which are located performers' dressing tents, properties, property and wardrobe trucks, vehicles used in pageant (the spec) and other equipment essential to the production.

Early American Circus.—During colonial days several English showmen brought small troupes to the United States. Among the first was Ricketts' circus which exhibited in the Greenwich theatre near the Battery, New York, in 1795. Probably the first American-born showman of note was Rufus Welch, who in 1818 managed a wagon show and later directed larger outfits. In Nov. 1826 the Mt. Pitt circus opened on Broome street, New York, in a building seating 3,500 persons, said at that time to be the largest place of amusement in America. Early circuses, but subsequent to the foregoing, were those of "Old" John Robinson, Dick Sands and Van Amburgh, the two last named making European tours in the 1840s.

Notable among American tent showmen may be named L. B. Lent, Adam Forepaugh, Dan Rice, the Sells brothers, W. C. Coup, P. T. Barnum, James A. Bailey and the Ringling brothers. Lent's historic New York circus played winter engagements in 14th street opposite the old Academy of Music, and toured under canvas during the summer months of the 1860s and early 1870s, his being the first show of size to travel by rail. Forepaugh was one of the tent world's most picturesque characters and the reputed precursor of the modern beauty contests. In 1880 he offered a prize for America's most beautiful woman, resulting in the selection of Louise Montague who thereafter rode in his street parade as "the $10,000 beauty."

Rice was the most famous of American clowns (who were originally pantomimists), and operator of boat shows on the Mississippi. The Sells brothers, Ephraim, Allen, Lewis and Peter, in 1872 founded the show bearing their name, giving distinct impetus to the "brother idea" in the circus world. Coup, a remarkable organizer who, in 1869, projected the largest circus known up to that time, originated performances in two rings, and assisted by Dan Costello persuaded P. T. Barnum to enter the circus field. Barnum, in his 60th year, brought his internationally advertised name and ability as a proprietor of museums, impresario, lecturer and author to the tent show world, thereby giving it incalculable publicity and advancement. Bailey, generally acknowledged to have been the master showman, introduced a third ring and devised intervening stages. Brilliant alike as an organizer, originator and financial genius, he directed superb productions throughout America and toured European countries at the head of the largest circus ever sent across the Atlantic.

The Ringling brothers, August G., Otto, Albert, Alfred T., Charles, Henry and John, were remarkable for their individual ability to direct separate departments of their show. Beginning in 1882 the Ringlings brought the show bearing their name to a size equalling that of the largest. Upon the death of Bailey they in 1907 purchased the Barnum and Bailey "Greatest Show on Earth," but conducted it as a separate institution until 1919 when they combined it with that bearing their name. The consolidation was directed by John Ringling, until his death in 1936.

The Modern Circus.—Unlike European circuses, the modern American circus sells a ticket which includes admission to both menagerie and circus performance. The big show program appeals largely to the eye, since the greater size of the modern main tent has rendered impossible a continuance of the talking clown and like audible features of the former one-ring circus.

The feats of human equestrians, aerialists, gymnasts, acrobats and clowns, interspersed with a number of trained jungle beasts and domestic animals, are presented in ground rings, on ground platforms (stages), from aerial apparatus and from steel arenas so distributed as to be enclosed within or above the confines of an oval courseway (hippodrome track) with the spectators seated in chairs (grandstand) and on bleachers (the blues) in such manner as to surround practically the entire area of action.

An average of 30 different tent shows (the largest requiring approximately 100 railway cars to transport it and the smallest using but a single car) tour more or less extensively through the United States each year. The touring season usually begins in April or May and continues into November. The intervening time is spent in winter quarters.

The biggest of the circuses, Ringling Bros. and Barnum & Bailey, makes its springtime debut in Madison Square Garden in New York city, and then plays a short engagement in a similar building in Boston. Thereafter it tours under canvas. There are not many circuses travelling by rail; most of the smaller ones are motorized, travelling the highways of the country much the same as their ancestors, the wagon or "mud" shows, did a century before. (E. P. N.; E. C. M.)

CIRENCESTER, a market town and urban district in the Cirencester and Tewkesbury parliamentary division of Gloucestershire, Eng., 17 mi. S.E. of Gloucester by road. Pop. of urban district (1951) 11,188. Area 9.1 sq.mi. Lying on the Churn river and at the edge of the Cotswolds, Cirencester is a hunting and an agricultural centre with twice-weekly markets and factories for agricultural equipment. It has many fine gray stone houses, built by rich wool merchants, and a magnificent parish church of St. John Baptist, dating from Norman times but mainly Perpendicular, with bells cast in Queen Anne's reign. The grammar school was founded in 1460.

The town occupies the site of the Romano-British Corinium Dobunorum, built at the junction of Fosse way, Ermine street and Akeman street. Remains of an amphitheatre are preserved near Querns hill but most of the Roman objects that have been found are housed in the Corinium museum (1938). After the battle of A.D. 628, Cirencester was rebuilt by the Saxons, slightly northwest of the old city, and later became a royal demesne. William the Conqueror granted the manor to William Fitzosbern who began building a castle which was razed to the ground under Stephen. A college of prebendaries, founded in Egbert's reign, was reconstructed by Henry I in 1117 as an Augustinian foundation. Henry II leased the manor to the abbot. In 1215 and 1253 the abbot obtained charters for fairs to be held during the octaves of All Saints and St. Thomas the Martyr; the wool trade gave these great importance—Camden records Cirencester as having "the greatest market for wool in England." In the 14th century the citizens rebelled against the abbot's authority and in 1403 Henry IV, as a reward for their help against the earls of Kent and Salisbury, granted them a guild merchant, but the abbot got this revoked by Henry V. Cirencester became a parliamentary borough in 1572, returning two members, but was deprived of separate representation in 1885. The abbey was destroyed at the Dissolution and an Elizabethan mansion (Abbey house) built on the site by Richard Master. Cirencester house was built at the same time by Sir John Danvers and in 1690 it became the home of the Bathurst family; it was rebuilt by the first earl Bathurst in 1718 and stands in a large park south of which is the Royal Agricultural college (incorporated 1845). In 1790 the Thames-Severn canal was extended to the town but was abandoned in 1911.

CIRE PERDUE: *see* SCULPTURE TECHNIQUE: *Casting and Finishing*.

CIRILLO, DOMENICO (1739–1799), Italian physician, botanist and revolutionist, was appointed as a young man to a botanical professorship and later travelled to France and England, where he was elected a fellow of the Royal society. On his return to Naples he was appointed successively to the chairs of practical and theoretical medicine. He wrote voluminously on scientific subjects, particularly botany, on which his most important work was *Fundamenta botanica sive Philosophiae botanicae explicatio*. On establishment of the Parthenopean republic in Naples, Cirillo became president of the legislative commission. When the town surrendered to Fabrizio Cardinal Ruffo, the vengeance of the royalists was wreaked upon Cirillo, and despite Lady Hamilton's intercession, Nelson had him hanged Oct. 29, 1799.

See L. Conforti, *Napoli nel 1799* (Naples, 1889); C. Giglioli, *Naples in 1799* (1903); C. Tivaroni, *L'Italia durante il dominio francese*, vol. ii.

CIRQUE, a French word used to denote a semicircular amphitheatre, with precipitous walls, at the head of a valley in a glaciated mountain region (Lat., *circus*, ring), generally resulting from basal sapping and erosion beneath the bergschrund of a glacier. The bergschrund is a large crevasse, in the form of a great symmetrical arc, parallel to the head of the névé (*see* GLACIER); it lies at a short distance from the exposed rock surface and separates the stationary from the moving ice, and in early summer,

COURTESY OF (1, 2, 4, 5) U.S. NATIONAL MUSEUM, (3) U.S. FISH AND WILDLIFE SERVICE

VARIOUS BARNACLES (Cirripedia, Order Thoracica)

1. Whale barnacle, *Coronula diadema* (suborder Balanomorpha) with portion of whale skin to which it was attached. To the *Coronula* in turn are attached two fleshy stalked barnacles, *Conchoderma auritum* (suborder Lepadomorpha); their specific name is derived from the two processes arising either side of the orifice in which the cirri can be seen. In *Conchoderma* the typical calcareous plates are quite vestigial. *Coronula diadema* at times is also called "whale louse" (*q.v.*). This species, so far as known, occurs only on humpback whales (*Megaptera*) and so is widely distributed in the north Atlantic and Pacific, with records also from Chile, Tonga and New Zealand. Specimen photographed is natural size, but the species attains a diameter of 3½ in. *Conchoderma auritum* seems to have much the same distribution, though not necessarily always attached to *Coronula*, as some specimens, unlike the whale barnacle, are known from ships' bottoms and iron buoys
2. Turtle barnacle, *Chelonibia testudinaria* (suborder Balanomorpha), from loggerhead turtle, Dry Tortugas, Florida. This barnacle is widely distributed on turtles in all temperate and tropic seas, Atlantic as well as Pacific. The specimen figured is natural size, but the species grows half again as large in the eastern tropical Pacific
3. Heavy marine growth, in considerable part barnacles (chiefly *Balanus* species), on propeller and struts of vessel
4. Goose barnacle, *Lepas anatifera* (suborder Lepadomorpha) on piece of driftwood from Gulf of Mexico. Specimens shown are about ⅔ natural size. Size of this species varies greatly, ranging up to 2 and 3 times that of those shown, with stalks here very short but in some cases three or more times as long as the shelly portion or capitulum. *Lepas anatifera* is common in all seas
5. Group of barnacles, showing large and massive form of *Balanus psittacus* (suborder Balanomorpha) from Chile, where it attains its largest growth, up to 9 in. in length and 3 in. in diameter. The fleshy portion of the body of these barnacles is much relished as a sea food in Chile

when the glacier commences to move, it opens and exposes the rock at its base to diurnal changes of temperature. Frost action then causes rapid disintegration downward at its base and backward upon such part of the rock surface as is exposed in the bergschrund beneath the stationary ice, thus producing the characteristic form of the cirque. The formation of cirques has played an important part in the development of the scenery of glaciated mountain tracts. Arêtes (sharp ridges) are formed by the intersection of two cirques, and pyramidlike peaks such as the Matterhorn and Snowdon are remnants left by the recession of three or more cirques. Cirques frequently contain lakes, for, owing to the action of the bergschrund, the floor slopes toward the mountain mass. W. D. Johnston (*Journ. of Geol.* vol xii p. 569) first recognized the processes giving rise to cirque formation by actually descending a bergschrund on the Mount Lyell glacier. Hollows of similar shape to cirques occur in limestone regions which may not have been glaciated. These are formed by aqueous solution and are not true cirques.

CIRRIPEDIA, a subclass of the Crustacea (*q.v.*), comprising the barnacles and acorn shells and certain parasitic forms related to them. All Cirripedes are completely sedentary in the adult state and with the loss of the power of locomotion they have become so modified as to show, at first sight, little trace of resemblance to the more ordinary Crustacea.

The common goose barnacle, *Lepas anatifera,* is found adhering to the bottom of ships and to floating timber. It has a fleshy stalk, fixed at one end to the supporting object and having at the other end a shell of five separate plates enclosing the body of the animal. The stalk is formed from the front part of the head, and the body, when exposed by opening the shell, is seen to be bent nearly at right angles to it. Embedded in the cement which fastens the end of the stalk to the support may be found the remains of the antennules which served for the attachment of the larva. The antennae are wanting, but within the shell the mouth is surrounded by mandibles, maxillulae and maxillae, and these are followed by six pairs of long, curled, two-branched appendages fringed with hairs. These appendages can be protruded from the slitlike opening of the shell, forming a kind of casting net for the capture of minute floating particles of food. The acorn shells which are abundant in most seas attached to rocks in shallow water, differ from the goose barnacle and its allies in having no peduncle. The shell is conical, cemented directly to the rock, and has an opening at the top closed by four movable valves. The shell has a more or less perfect radial symmetry. Barnacles are important ship fouling organisms, which may impede the speed of a ship by 50%, delaying voyages, increasing fuel consumption, the wear and tear on machinery and frequent loss of time in docking to remove offending growths. It has been estimated (1927) that the annual cost of fouling was $100,000,000. The fleshy parts of the largest barnacle are relished in Chile, where *Balanus psittacus* grows to imposing size, 9 in. in height by 3 in. in diameter; other large balanoids are eaten by the aborigines on the northwest coast of America. In Japan smaller species are cultivated on clumps of bamboo set along shore. At intervals of three months the attached barnacles are beaten off for use as manure.

Allied to the more normal Cirripedia just described are a number of more degenerate and, for the most part, parasitic forms. The most degenerate are the members of the order Rhizocephala, of which the genus *Sacculina,* a common parasite of crabs, is a familiar example. It has a simple saclike body attached under the abdomen of the crab by a short stalk from which rootlike processes ramify throughout the internal organs of the host. The body is enveloped by a fleshy mantle with a small opening and is without appendages, mouth or alimentary canal, the only organs which are well developed being those of the reproductive system. There is no trace of Arthropodous structure and only the larval development allows *Sacculina* to be referred to the Cirripedia. For the effect of *Sacculina* on its host, *see* SEX. Largest of the Rhizocephala is *Briarosaccus callosus* found living on a lithodid crab taken from more than 250 fathoms off the southeastern United States. This huge, tumourlike parasite is nearly 4 in. long, more than 2 in. high, and 1¼ in. thick.

Unlike the majority of Crustacea and, indeed, of Arthropoda in general, the Cirripedia are nearly all hermaphrodite, but in a few species dwarf and degenerate male individuals are found attached at, or within, the opening of the shell of the normal individuals. The latter may be, as usual, hermaphrodites, in which case the males were termed by Darwin "complemental males" but in a few instances the large individuals are purely female and the separation of the sexes is complete. It was demonstrated (1942) in the Rhizocephalan *Peltogaster paguri* that the cypris larvae attaching within the mantle cavity of young Peltogasters become masculinized to serve as functional males.

Most Cirripedes are hatched from the egg in the nauplius stage, but the earliest larvae are characterized by the development of spines and processes from the body and in some oceanic species these spines are of relatively enormous length. At a later stage the larva is enclosed in a bivalve shell superficially resembling that of an Ostracod and on this account it is known as the "cypris" stage. Like the nauplius stages the cypris swims freely but ultimately it attaches itself by the antennules, which are provided with glands producing an adhesive secretion. The shell is cast off, leaving a membranous mantle within which calcareous plates appear, at first, apparently, always five in number.

The Cirripedia are almost exclusively marine animals, only one or two species penetrating a little way into estuaries and the like. Certain species attach themselves to whales, marine turtles, or the larger Crustacea, and truly parasitic forms are found on Echinoderms and Crustacea. The earliest fossils definitely referable to the Cirripedia occur in the Rhaetic formation and belong to the Lepadomorpha.

Though complicated by the obscure relationship of parasitic forms to more normal Cirripedes, the classification generally adopted is as follows:

Order *Thoracica,* with six pairs of thoracic appendages, divided into four suborders: *Lepadomorpha,* the stalked barnacles (*Lepas, Scalpellum, Mitella*); *Verrucomorpha,* asymmetrical sessile forms (*Verruca*), *Brachylepadomorpha* (sessile, fossil only, *Pycnolepas, Brachylepas*); *Balanomorpha,* the sessile acorn shells and rock barnacles (*Balanus, Chthamalus, Coronula, Chelonibia*).

Order *Acrothoracica,* somewhat degenerate forms with fewer thoracic appendages, boring in shells and corals (*Alcippe*).

Order *Ascothoracica,* six pairs of thoracic appendages, only Cirripede with definite, at times segmented, abdomen, parasitic on Coelenterates and Echinoderms; affinities obscure (*Laura, Dendrogaster*).

Order *Apoda,* no thoracic limbs, only known specimen described by Darwin; from mantle cavity of another Cirripede (*Proteolepas*).

Order *Rhizocephala,* degenerate parasites of Decapod Crustacea, only Cirripedes without any alimentary canal; no trace of segmentation in adult, wholly without appendages (*Sacculina, Peltogaster*). (*See* ACORN SHELLS; BARNACLE; CRUSTACEA.)

(W. T. C.; W. L. ST.)

CIRTA: *see* CONSTANTINE, ALGERIA.

CISCO, a city of Eastland county, Texas, U.S., 108 mi. W. by S. of Ft. Worth on federal highways 80 and 283, and served by the Missouri-Kansas-Texas and the Texas and Pacific railways. Pop. (1950) 5,230. It is in a gas and oil region; has several manufacturing industries and is an important market for horses, fruits, cattle, corn, wheat, peanuts, poultry and other agricultural products. Just north of the city is Lake Cisco and Williamson dam, and just below it is an immense concrete swimming pool. Cisco was founded in May 1881 and was incorporated in 1883. It was named after John W. Cisco, banker and director of the Texas Central railway.

CISSEY, ERNEST LOUIS OCTAVE COURTOT DE (1810–1882), French general, was born at Paris on Sept. 23, 1810, and after passing through St. Cyr, entered the army in 1832. He served in Algeria and in the Crimean War, and became general of division in 1862. When the Franco-German War broke out in 1870, de Cissey was given a divisional command in the army of the Rhine, and he was included in the surrender of Bazaine's

army at Metz. He held a command in the army engaged in the suppression of the Commune. From July 1871 de Cissey sat as a deputy, and he had already become minister of war. He occupied this post several times during the critical period of the reorganization of the French army. In 1880 he was accused of treasonable relations with a German agent, but was exonerated by a court of inquiry. He died on June 15, 1882 in Paris.

CISSOID: *see* CURVES, SPECIAL.

CIS-SUTLEJ STATES. Former name for part of south Punjab. Sikh chiefs south of the Sutlej passed under British protection in 1809, and the name was applied to the country south of the Sutlej and north of the Delhi territory. Before 1846 the greater part was independent, the chiefs being subject merely to control from the agent of the governor-general for the Cis-Sutlej states at Umballa. After the first Sikh War the full administration of the territory became vested in this officer. In 1849 the Punjab was annexed and the Cis-Sutlej States commissionership, comprising Ambala, Ferozepore, Ludhiana, Thanesar and Simla districts, was incorporated with the new province. The name continued to be used until 1862, when, Ferozepore having been transferred to the Lahore division, and a part of Thanesar to the Delhi division, it became obsolete.

CIST, in Greek archaeology, a wicker-work receptacle used in the Eleusinian and other mysteries to carry the sacred vessels; and also, in prehistoric archaeology, a coffin formed of flat stones placed edgeways with another flat stone for a cover. Cist-burial was probably introduced into the British Isles by the Beaker-folk about 1800 B.C., but lasted in some parts down to the present era. The cist was generally, but not always covered by a round barrow or cairn.

CISTERCIANS, otherwise GREY or WHITE MONKS (from the colour of the habit, over which is worn a black scapular or apron). In 1098 St. Robert, born of a noble family in Champagne, at first a Benedictine monk, and then abbot of certain hermits settled at Molesme near Châtillon, being dissatisfied with the manner of life and observance there, migrated with twenty of the monks to a swampy place called Cîteaux in the diocese of Châlons, not far from Dijon. Count Odo of Burgundy here built them a monastery, and they began to live a life of strict observance according to the letter of St. Benedict's rule. In the following year Robert was compelled by papal authority to return to Molesme, and Alberic succeeded him as abbot of Cîteaux and held the office till his death in 1109, when the Englishman St. Stephen Harding became abbot, until 1134. In 1112, however, St. Bernard and thirty others offered themselves to the monastery, and a rapid and wonderful development at once set in. The next three years witnessed the foundation of the four great "daughter-houses of Cîteaux"— La Ferté, Pontigny, Clairvaux and Morimond. With Clairvaux Bernard's work is specially associated. At Stephen's death there were over 30 Cistercian houses; at Bernard's (1154) over 280; and by the end of the century over 500; and the Cistercian influence in the Church more than kept pace with this material expansion, so that St. Bernard saw one of his monks ascend the papal chair as Eugenius III.

The Cistercians rejected alike all mitigations and all developments of St. Benedict's rule, and tried to reproduce the life exactly as it had been in his time; indeed in various points they went beyond it in austerity. The most striking feature in the reform was the return to manual labour, and especially to field-work, which became a special characteristic of Cistercian life. In order to make time for this work they cut away the accretions to the divine office which had been steadily growing during three centuries, and in Cluny and the other Black Monk monasteries had come to exceed greatly in length the regular canonical office.

It was as agriculturists and horse and cattle breeders that, after the first blush of their success and before a century had passed, the Cistercians exercised their chief influence on the progress of civilization in the later middle ages: they were the great farmers of those days, and many of the improvements in the various farming operations were introduced and propagated by them; it is from this point of view that the importance of their extension in northern Europe is to be estimated. They depended for their income wholly on the land. This developed an organized system for selling their farm produce, cattle and horses, and notably contributed to the commercial progress of the countries of western Europe. Thus by the middle of the 13th century the export of wool by the English Cistercians had become a feature in the commerce of the country. Farming operations on so extensive a scale could not be carried out by the monks alone, whose choir and religious duties took up a considerable portion of their time; and so from the beginning the system of lay brothers was introduced on a large scale. The lay brothers were recruited from the peasantry and were simple uneducated men, whose function consisted in carrying out the various field-works and plying all sorts of useful trades; they formed a body of men who lived alongside of the choir monks, but separate from them, not taking part in the canonical office, but having their own fixed round of prayer and religious exercises. A lay brother was never ordained, and never held any office of superiority. It was by this system of lay brothers that the Cistercians were able to play their distinctive part in the progress of European civilization. But it often happened that the number of lay brothers became excessive and out of proportion to the resources of the monasteries, there being sometimes as many as 200, or even 300, in a single abbey. On the other hand, at any rate in some countries, the system of lay brothers in course of time worked itself out; thus in England by the close of the 14th century it had shrunk to relatively small proportions, and in the 15th century the régime of the English Cistercian houses tended to approximate more and more to that of the Black Monks.

For a hundred years, till the first quarter of the 13th century, the Cistercians supplanted Cluny as the most powerful order and the chief religious influence in western Europe. But then in turn their influence began to wane, chiefly, no doubt, because of the rise of the mendicant orders, who ministered more directly to the needs and ideas of the new age. But some of the reasons of Cistercian decline were internal. In the first place, there was the permanent difficulty of maintaining in its first fervour a body embracing hundreds of monasteries and thousands of monks, spread all over Europe; and as the Cistercian very *raison d'être* consisted in its being a "reform," a return to primitive monachism, with its field-work and severe simplicity, any failures to live up to the ideal proposed worked more disastrously among Cistercians than among mere Benedictines, who were intended to live a life of self-denial, but not of great austerity. Relaxations were gradually introduced in regard to diet and to simplicity of life, and also in regard to the sources of income, rents and tolls being admitted and benefices incorporated, as was done among the Benedictines; the farming operations tended to produce a commercial spirit; wealth and splendour invaded many of the monasteries, and the choir monks abandoned field-work.

The later history of the Cistercians is largely one of attempted revivals and reforms. The general chapter for long battled bravely against the invasion of relaxations and abuses. In 1335 Benedict XII., himself a Cistercian, promulgated a series of regulations to restore the primitive spirit of the order, and in the 15th century various popes endeavoured to promote reforms. All these efforts at a reform of the great body of the order proved unavailing; but local reforms, producing various semi-independent offshoots and congregations, were successfully carried out in many parts in the course of the 15th and 16th centuries. In the 17th another great effort at a general reform was made, promoted by the pope and the king of France; the general chapter elected Richelieu (commendatory) abbot of Cîteaux, thinking he would protect them from the threatened reform.

In this they were disappointed, for he threw himself wholly on the side of reform. So great, however, was the resistance, and so serious the disturbances that ensued, that the attempt to reform Cîteaux itself and the general body of the houses had again to be abandoned, and only local projects of reform could be carried out.

The Reformation, the ecclesiastical policy of Joseph II., the French Revolution, and the revolutions of the 19th century, almost wholly destroyed the Cistercians; but some survived, and

after the beginning of the last half of the 19th century there was a considerable recovery.

In 1933 there were 9 congregations of Cistercians with 37 monasteries, a provostship and many residences. The order numbered about 1,000 members, of whom about 700 were priests. The general of the order resides in Rome.

In 1930 the Cistercians made a foundation at Spring Bank, Wis. Prior to this the order had been represented in the United States by the Strict Observance or Trappists (*q.v.*).

Accounts of the beginnings of the Cistercians and of the primitive life and spirit will be found in the lives of St. Bernard, the best whereof is that of Abbé E. Vacandard (1895); also in the Life of St. Stephen Harding, in the *English Saints*. *See* also Henry Collins (one of the Oxford Movement, who became a Cistercian), *Spirit and Mission of the Cistercian Order* (1866). Useful sketches, with references to the literature, will be found in the *Catholic Encyclopaedia*, art. "Cistercians"; Herzog-Hauck, *Realencyklopädie*, "Cistercienser"; and Heimbucher, *Orden und Kongregationen* (1933), i. §46. On the English houses, *see* F. A. Gasquet's *English Monastic Life;* and on the Cistercian polity, *see* the same writer's "Sketch of Monastic Constitutional History," prefixed to Eng. tr. of Montalembert's *Monks of the West* (1895).

CISTUS, a genus of the family Cistaceae. The members of the family live in dry, sunny places, especially on a sandy or chalky soil.

There are 20 species in the Mediterranean region; many are cultivated ornamental shrubs, in English-speaking countries commonly called rock-rose.

C. villosus and *C. ladaniferus* yield the resin ladanum, which is not to be confused with the hypnotic laudanum.

CITADEL, a municipal fortress. The beginnings of the citadel are remote. At Tanis in Egypt there is a very ancient example; roughly quadrangular, it was built to command a stream and the adjacent ground.

During the 12th dynasty of the first Theban empire a most formidable citadel was evolved, typified at Semneh, where a low wall of first defense rises upon a platform; the citadel proper is a series of crenelated buttress-redoubts projecting at short intervals from a high, rectangular wall, with an additional highly fortified projection at one corner; scaling would have been impossible without fatal casualties.

Ancient Greek citadels were usually of Cyclopean construction (*see* CYCLOPAEAN MASONRY) but that of Tiryns (*q.v.*) has upper walls of brick. It contains the king's palace, a fact which does not change its *rôle* as the true municipal fortress but which points to the origin of the municipality itself. The amalgamation of several hamlets into a *polis* or city, very frequently depended upon the existence of an *acron*, or height, which might be fortified and which became a storehouse of provisions and ammunition as well as the shrine of the god, the home of the king and the refuge of the people.

Just as the acropolis of Athens or the walled hill of the temple of Solomon in Jerusalem were vital municipal influences, so the capitol was the consolidating and protecting factor in Rome. But the citadel of Roman cities in general was less important than those of Greece. In strong countries not contiguous upon others of the same status citadels are rare because they are unnecessary. The Roman *castella* covered Europe and a part of Asia and Africa at one time; they were military centres around which a town might group itself, but they were never, in their beginnings, an integral element of normal municipal life. They existed for the empire and for themselves, and the fact that they protected municipalities was incidental.

After Rome, here and there, the citadel recovered its importance. The growth of feudalism meant the decline of the free, or nominally free, city. It should not be said, however, that in feudal times citadels ceased to be built; sometimes the right of fortification was granted by a lord and sometimes it was acquired by arms; the lord's castle might be a true citadel, or a new one might be erected by the city-State. As a type of architecture distinguished from the castle, the modern citadel is generally said to date from 1568, when the duke of Alva built one to dominate Antwerp. But the rapid multiplication of small States in the late middle ages made the citadel common in Europe.

See CASTLE: *Bibliography;* FORTIFICATION; Daremberg and Saglio, *Dict. ant. class.*, "Acropole"; Planat, *Enc. archit.*, "Citadelle"; C. Enlart, *Man. archéol. fr.*

CITATION, in law, a summons to appear, answering to a writ of summons at common law, and it is now in English probate practice an instrument issuing from the principal probate registry, chiefly used when a person, having the superior right to take a grant, delays or declines to do so, and another, having an inferior right, desires to obtain a grant; the party having the prior right is cited to appear and either to renounce the grant or show cause why it should not be decreed to the citator. In divorce practice, when a petitioner has filed his petition and affidavit, he extracts a citation; *i.e.*, a command drawn in the name of the sovereign and signed by one of the registrars of the court, calling upon the alleged offender to appear and make answer to the petition. In Scots law, citation is the judicial notice served upon a person convening him to court as a party litigant, a witness, a haver of documents, or a juror. Citation, as a legal term, is used in the United States to show a reference to a particular law, decision or treatise which tends to support the proposition advanced in a brief or argument. In such cases the volume, section or page, or all, is indicated.

Citation is also a military term denoting special mention for gallantry in action of a military unit, or of an individual under arms. In most nations the Citation is issued by some general officers in charge of a division or brigade, or is published by the War Department. It frequently appears in the General Orders of a military command, outlining the heroic action of those concerned. In the United States military forces the individual cited is given a silver star in recognition of his service. The *fourragère* or citation cord is given by France to members of a unit receiving such an award. In the British and U.S. military forces, this *fourragère* is not given but units having received it from the French or other governments are allowed to wear it. A typical General Order issued by the military command of the United States was published in General Order on July 9, 1918 (General Order 112) by the commander of the American forces, General John J. Pershing, citing the heroic action of the First and Second Divisions.

CÎTEAUX, a village of eastern France, in the department of Côte d'Or, 16 mi. S.S.E. of Dijon. It is celebrated for the great abbey founded by Robert, abbot of Molesme, in 1098, which became the headquarters of the Cistercian order. The buildings which remain date chiefly from the 18th century.

CITHAERON, now called from its pine forests Elatea, a mountain range (4,872 ft.), separating Boeotia from Megaris and Attica. Its west end reaches the Corinthian Gulf; eastward it is separated from Mount Parnes by the pass through Panactum and Phyle. It was famous in Greek mythology. Here Actaeon was changed into a stag, Pentheus was torn to pieces by the Bacchantes and the infant Oedipus was exposed. It was the scene of the mystic rites of Dionysus, and the festival of the Daedala in honour of Hera. The carriage-road from Athens to Thebes traverses the picturesque pass of Dryoscephalae ("Oak-heads"), guarded on the Attic side by the ruined fortress of Ghyphtokastro ("Gipsy Castle"). Plataea is situated on the north slope, and the strategy of the battle of 479 B.C. was considerably affected by the necessity for the Greeks to keep open the passes (*see* PLATAEA), of Dryoscephalae, and the roads farther west from Plataea to Athens and to Megara.

CITHARA, one of the most ancient stringed instruments, may be traced back to 1700 B.C. among the Semitic races, in Egypt, Assyria, Asia Minor, Greece and the Roman empire, whence the use of it spread over Europe. Having as its leading feature a sound-box or sound-chest which consisted of two resonating tables, either flat or delicately arched, connected by ribs or sides of equal width, the cithara may be regarded as an attempt to improve upon the lyre (*q.v.*), while retaining some of its features.

The strings, varying in number from four to 20 and made of gut, hemp or silk, were vibrated by means of the fingers or of a plectrum, according to the requirements of the music and the

different quality of tone desired. Like the lyre the cithara was made in many sizes, according to the pitch required and the use to which the instrument was to be put. It was in Greece the instrument alike of the professional singer or citharoedus (*κιθαρῳδός*) and, of the instrumentalist or citharista (*κιθαριστής*), and thus served the double purpose of (1) accompanying the voice (a use placed by the Greeks far above mere instrumental music) in epic recitations and rhapsodies, in odes and lyric songs; and (2) of accompanying the dance. It was also used for playing solos at the national games, at receptions and at trials of skill.

From the cithara by successive stages was evolved the guitar. The first of these steps produced the rotta, by the construction of body, arms and transverse bar in one piece. The addition of a finger board, stretching like a short neck from body to transverse bar, leaving on each side of the finger board space for the hand to pass through in order to stop the strings, produced the crwth or crowd (*q.v.*), and brought about the reduction in the number of the strings to three or four. The conversion of the rotta into the guitar (*q.v.*) was an easy transition effected by the addition of a long neck to a body derived from the oval rotta. When the bow was applied the result was the guitar or troubadour fiddle.

The *cittern* (*q.v.*), a later descendant of the cithara, although preserving the characteristic features of the cithara, the shallow sound chest with ribs, adopted the pear-shaped outline of the eastern instruments of the lute tribe.

CITIUM (Gr. *Kition*), the principal Phoenician city in Cyprus, situated on the southeast coast at the north end of modern Larnaca (*q.v.*). Converging currents from east and west greatly facilitated ancient trade. To south and west the site is protected by salt lagoons. The earliest remains go back to an Aegean colony of Mycenaean age (*c.* 1400–1100 B.C.), but in historic times Citium is the centre of Phoenician influence in Cyprus. The biblical name Kittim, representing Citium, is, in fact, used quite generally for Cyprus as a whole; later also for Greeks and Romans in general. In a list of the allies of Assur-bani-pal of Assyria in 668 B.C. a king, Damasu, of Kartihadasti (Phoenician for "Newtown") occurs where Citium would be expected. A Phoenician dedication to "Baal of Lebanon," found there, suggests that Citium may have belonged to Tyre: and an official monument of Sargon II indicates that Citium was the administrative centre of Cyprus during the Assyrian protectorate (709–668 B.C.). During the Greek revolts of 500, 386 *et seq.*, and 352 B.C., Citium led the side loyal to Persia and was besieged by an Athenian force in 449 B.C. It remained a considerable city even after the Greek cause triumphed with Alexander. But it suffered repeatedly from earthquakes and in mediaeval times its harbour became silted and the population moved to Larnaca, on the open bay. Harbour and citadel have quite disappeared, the latter having been used to fill up the former shortly after the British occupation; some gain to health resulted, but an irreparable loss to science. There are traces of the circuit wall and many tombs.

CITIZEN: *see* NATIONALITY; NATURALIZATION LAWS.

CITOLE, an obsolete musical instrument of which the exact form is uncertain. It has been supposed to be another name for the psaltery (*q.v.*).

CITRANGE, the hybrid tree and its fruit produced by crossing any variety of sweet orange (*Citrus sinensis*) with the trifoliate orange (*Poncirus trifoliata*). Since 1892 U.S. scientists have endeavoured to produce some form of *Citrus*, or a relative, which would thrive in a winter temperature subnormal for oranges. Plants raised from cross-fertilized fruits, using these two species as reciprocal parents have been tested. By 1943 there were less than a dozen varieties of citranges of restricted cultural importance. Some citranges closely resemble oranges; all are inferior to the orange in flavour, but are serviceable in flavouring cakes or jams and for citrangeade. The trees and fruit endure considerable frost. Some varieties of citrange are used for rootstocks for oranges and grapefruit. Citrangequats, trigeneric hybrids made by crossing a kumquat (*Fortunella margarita*) with a citrange, are cultivated as novelties in the United States. (L. D. B.)

CITRIC ACID $C_6H_8O_7$, 2-hydroxypropane-1:2:3-tricarboxylic acid,

$$CO_2H.CH_2.C(OH)(CO_2H).CH_2.CO_2H,$$

is one of the most common plant acids. It was first isolated in a pure form from lemon juice by Karl Wilhelm Scheele in 1784. It occurs as the free acid in many other acid fruits and usually as a salt in most other parts of plants. Almost all plant materials which have been tested with the delicate modern methods contain some citric acid or citrate, some only a few milligrams per kilogram, others, such as lemons, up to 50 g. per kilogram. It is also a constituent of many animal tissues and body fluids. Milk contains up to 1.2 g. per litre, bone (wet) and teeth about 3 g. per kilogram, semen about 5 g. per litre, blood serum about 0.025 g. per litre, human urine between 0.2 g. and 1.2 g. per litre. The acid has been prepared commercially from the juice of lemons and limes, but this method is now largely superseded by the mould fermentation process: C. Wehmer discovered in 1893 that citric acid can be obtained from sugar solutions on which the mould *Citromyces* has been allowed to grow. In 1916 C. Thom and J. N. Currie found that some strains of *Aspergillus niger* produced much more citric acid than Wehmer's organism. This was the starting point of the modern fermentation method. The fermentation is a complex oxidative process; the sugar is probably first broken down to small units such as pyruvic acid, acetaldehyde, acetic acid and carbon dioxide, which recombine to form citric acid. It is usually carried out in shallow vessels which allow free access of air. About ten days after spore inoculation and incubation at 30° C. to 32° C. the process is completed. Yields as high as 87% of the weight of the sugar used have been reported; usually, however, about 60% can be recovered; sucrose gives the best yields, but cheaper sources like molasses are also satisfactory raw materials. A deep tank fermentation process of the type used in the manufacture of penicillin has been developed in the United States, using *Aspergillus wentii*. The mould fermentation process is used in Britain, the United States, Belgium, France, Germany and Czechoslovakia.

Pure citric acid is usually prepared by way of the calcium salt. The crude solution of the acid, after heating and filtration, is neutralized with lime and chalk and boiled. The precipitate of calcium citrate thus obtained is decomposed with dilute sulphuric acid; the solution is filtered to remove the calcium sulphate and concentrated in vacuum pans. The acid crystallizes in colourless rhombic prisms of the composition $C_6H_8O_7+H_2O$.

The first synthesis of citric acid was accomplished by L. E. Grimaux and P. Adam in 1880. It dissolves readily in water and is also soluble in ethyl alcohol and in ether. On heating, the crystals soften between 70° C. and 100° C. and lose water. On further heating the substance becomes again dry and finally melts at 153° C. At about 175° C. it loses a molecule of water and is transformed into (trans)-aconitic acid ($C_6H_6O_6$) or propene-1:2:3:tricarboxylic acid:

$$CO_2H.CH:CH.CH_2.CO_2H.$$
$$\qquad\qquad\quad |$$
$$\qquad\qquad CO_2H$$

Above 170° C. carbon dioxide and an oily distillate which yields crystals of itaconic acid ($C_5H_6O_4$) are formed. When citric acid is heated in dilute sulphuric acid, aconitic acid is formed; fuming sulphuric acid produces acetone dicarboxylic acid ($C_5H_6O_5$), water and carbon monoxide.

As a tribasic acid, citric acid forms three series of salts. The salts of the alkaline metals are readily soluble in water. The neutral salts of the alkaline earths are only moderately soluble. Calcium citrate is less soluble in hot water than in cold.

Citric acid plays an important part in the metabolism of animals and plants. Most animal tissues, many plants and some micro-organisms convert citric acid reversibly into cis-aconitic

acid and isocitric acid (1-hydroxypropane-1:2:3:tricarboxylic acid):

$$CO_2H.CH(OH).CH.CH_2.CO_2H$$
$$\quad\quad\quad

the designation. The official style of "city" does not necessarily involve the possession of municipal power greater than those of the ordinary boroughs, nor indeed the possession of a corporation at all (*e.g.*, Ely). In the United States and the British dominions, on the other hand, the official application of the term "city" depends on the kind and extent of the municipal privileges possessed by the corporations, and charters are given raising towns and villages to the rank of cities. Both in France and England the word is also used to distinguish the older and central nucleus of some of the large towns, *e.g.*, the *cité* in Paris, and the "square mile" under the jurisdiction of the lord mayor which is the "City of London." In common usage, however, the word is loosely applied to any large centre of population, and in the United States any town, whether technically a city or not, is usually so designated, with little regard to its actual size or importance.

As the translation of the Greek *πόλις* or Latin *civitas*, the word involves the ancient conception of the state or "city-state," *i.e.*, of the state as not too large to prevent its government through the assembled body of citizens, and is applied not to the place but to the whole body politic. From this conception both the word and its dignified connotation are without doubt historically derived. On the occupation of Gaul the Gallis states and tribes were called *civitates* by the Romans, and subsequently the name was confined to the chief towns of the various administrative districts. These were also the seats of the bishops. It is thus affirmed that in France from the 5th to the 15th century the name *civitas* or *cité* was confined to such towns as were episcopal sees, and Du Cange (*Gloss.* s.v. *civitas*) defines that word as *urbs episcopalis*, and states that other towns were termed *castra* or *oppida*. How far any such distinction can be sharply drawn may be doubted. No definite line can be drawn between those English towns to which the name *civitas* or *cité* is given in mediaeval documents and those called *burgi* or boroughs (*see* J. H. Round, *Feudal England;* F. W. Maitland, *Domesday Book and After*). It was, however, maintained by Coke and Blackstone that a city is a town incorporate which is or has been the see of a bishop. It is true that the actual sees in England all have a formal right to the title and the boroughs erected into episcopal sees by Henry VIII thereby became "cities"; but towns such as Thetford, Sherborne and Dorchester are not so designated, though they are regularly incorporated and were once episcopal sees. In 1075 the bishop's see was transferred from Sherborne to Salisbury. After eight and a half centuries, by an order published in the *London Gazette* of Feb. 10, 1924, Sherborne was re-created a suffragan bishopric. On the other hand it has only been since the latter part of the 19th century that the official style of "city" has, in Great Britain, been conferred by royal authority on certain important towns which were not episcopal sees, Birmingham in 1889 being the first to be so distinguished. London contains two cities, one (the City of London) outside, the other (the City of Westminster) included in the administrative county.

For the history of the origin and development of modern city government *see* BOROUGH and COMMUNE: *Mediaeval.*

BIBLIOGRAPHY.—For American cities, *see:* William B. Munro, *The Government of American Cities*, 4th ed. (1924); Chester C. Maxey, *An Outline of Municipal Government* (1924).

CITY CLERK, the chief clerical official of the cities of the United States performing most of the duties of an English town clerk. In cities under the council form of government he is usually elected either as a partisan candidate or candidate without regard to party lines. In cities under the commission or commission-manager form of government, he usually is appointed by the mayor subject to the approval of the commission, or is chosen by the commission. He may serve for an indefinite number of terms. The city clerk keeps the minutes of the meetings of the city council or commission. He also keeps all other city records, and in many states has authority to issue licences. He usually has a force of deputies appointed by him or by the authority which appoints him, or selected by civil service regulations.

See H. G. James, *Local Government in the United States* (1921); C. C. Maxey, *An Outline of Municipal Government* (1924).

CITY GOVERNMENT. The government of a modern city bears little resemblance to its historical coufiterpart. But as the walled mediaeval town often left its impression at the heart of the modern European metropolis, so too did obsolete governmental patterns linger on to complicate the administration of modern municipal services. This lag was evident in world-wide efforts to cope with the suburban overflow from great metropolitan centres, but it appears in many other ways and suggests the starting point for understanding modern city government—*i.e.*, the continuing struggle to keep pace with the problems of rapid urbanization.

Early municipal governments evolved to meet the limited demands of small towns serving rural populations. The industrial revolution converted the cities into workshops. The accompanying revolution in communication made them the commercial, cultural and intellectual centres of their respective countries. Thus economic drawing power combined with the attractions of a more sophisticated urban culture to sustain a world-wide urban migration.

With the urban migration came new public services. Crime, fire, poverty and pestilence grew in seriousness with the size of the city. Polluted wells yielded to public water supply; open sewers gave way to sanitary waste disposal; contagious diseases came under public health regulations; industrial unemployment required new forms of public assistance; fire and health hazards dictated more stringent building regulation; growing congestion impelled attention to better planning of streets and open spaces. The services provided by city governments became increasingly important to the urban citizen. But each step required new legal powers, more specialists and additional funds. The pressure began to crack the shell of outmoded institutions.

Municipal Patterns in England and North America.—As the industrial revolution spread over England, the European continent, the United States and finally Japan, the 19th century saw marked changes in the structure of city government. In England, Elizabethan poor laws collapsed early under the impact of industrial unemployment. The revised Poor Law of 1834 set the pattern for early efforts to adjust traditional local institutions to changing needs by creating new governmental areas (poor law unions). It provided for locally elected governing boards, a paid professional staff and central government supervision of these local authorities. This use of *ad hoc*, or single-purpose, authorities to carry out new municipal functions spread in England until a hopeless confusion of jurisdictions, tax rates and organization forced a series of reforms. Consolidation began as early as 1871, but not until the acts of 1929 and 1933 was a more rational system of local government areas and authorities created.

By mid-20th century most of England's larger cities operated as county boroughs. These all-purpose authorities are combined city-county governments enjoying the powers of both. The area outside the county boroughs is divided into administrative counties, which are further subdivided into boroughs (called noncounty boroughs), urban districts and rural districts. Most noncounty boroughs and urban districts are cities between 5,000 and 50,000 population, although a few are larger. Whether he lives in a county borough, noncounty borough or urban district, the urban dweller elects a council as his principal governing body. One-third of the members retire each year. Both the county borough and noncounty borough councils select aldermen, up to one-third the number of councillors, for six-year terms. The aldermen sit and vote as members of the council. The council also elects the mayor who presides over the council but has no important executive duties. Administration is supervised by council committees appointed for each important department of government. The committee selects the professional head of the service and provides close policy guidance for his activities. There is no single chief executive, although the borough clerk is a connecting link between departments.

The Local Government Boundary commission was appointed in 1945 to continue the rationalization of local areas. The Local Government Act of 1948 made important changes in the system of government financing and property valuation for tax purposes, in part because the services undertaken by local governments under the National Health Service Act of 1946 and the National Assistance Act of 1948 outran local tax resources. These acts provided

extensive health services and augmented aid to the aged and infirm. The act of 1948 provided a system of equalization grants from the national government to help underwrite the new functions.

In the United States, both national and state governments were slow to face the emerging urban problems of the 19th century. The cities, reflecting the American suspicion of government, were initially governed through an ineffectual system of two-chamber city councils, mayors without power and a multitude of elected officials. Then, also, the traditional legal status of the city as a corporation, operating within the strict bounds of specified powers delegated from the state governments, was a major handicap. Cities often lacked the legal powers needed to exercise necessary controls over private action. Rurally dominated legislatures were either indifferent to urban problems or meddled directly in local affairs to get special privileges. When new municipal functions were authorized, state laws typically required that they be administered by semi-independent commissions detached from the administration of the mayor. In the resulting confusion local officials, shielded by dispersed responsibility, often took advantage of the opportunities for corruption in franchises for utilities, enforcement of building codes, construction of public works, etc.

By the end of the 19th century, municipal corruption had become a national scandal in the United States and several reform movements gathered momentum. Among them were drives for greater home rule for cities, a shorter ballot, more stringent enforcement of tenement-control laws, reform of police systems, city planning and stronger executive control over city government. The National Municipal league, organized in 1894, became the educational centre for changes in the structure of government. It advocated and provided legal guidance for strengthening the position of the mayor, reducing the size of city councils, dispensing with superfluous elected officials and abolishing many independent boards and commissions. With public sentiment for reform growing, many states adopted municipal home-rule laws. These permitted a range of experimentation and local initiative that raised U.S. city government from disrepute to advanced professionalization within a generation.

Three patterns of city government attracted attention in the U.S. during the first half of the 20th century. One—the commission form—is principally of historical interest. It was launched in Galveston, Tex., in 1901, and later widely imitated. The members (usually five) of a small council serve as the administrative heads of a group of services. The mayor is simply the presiding member of the council and of no special importance. With time, the dispersal of responsibility in the scheme revealed serious weaknesses, and the commission form is gradually dwindling away. The two forms of government growing in importance by mid-century were the strong mayor and the city manager. Under the strong-mayor form a popularly elected chief executive is given substantial authority to make appointments, initiate the budget, supervise government departments, propose public policy and veto council actions. This became the dominant pattern in the larger cities. Fifteen of the 17 cities with more than 500,000 population operated under some form of mayor-council government in 1953. The powers of the mayor vary widely, however, and the trend to centralized administrative authority is restricted by the continuing tendency for state legislatures to place new functions under semi-independent boards. Smaller cities moved more slowly toward a strong executive than did the larger. A large proportion continued at mid-century to operate under strong-council, weak-mayor forms, with the council and its committees the dominant element. The city-manager plan enjoyed startling success after its first introduction at Sumter, S.C., in 1912. It follows the corporation pattern. The council is essentially an elected board of directors which appoints a professional manager to direct the city's administration. It is usually small and nonpartisan, with the members elected at large. The manager recommends policy, prepares the budget, makes appointments and exercises direction over the administrative departments. He does not, in contrast with the strong mayor, play an active part in political action designed to get his recommendations adopted. This is left to the council. The system worked well and spread rapidly. Of the 2,527 cities with more than 5,000 people in 1953, about 28% operated under the manager plan, 52% under some form of mayor-council, 14% under the commission form and the remainder under a form of town meeting.

In the United States, as in England, the growth in governmental services accelerated after 1930. Much of the burden of administering and financing these services fell on local governments. Population shifts during and after World War II meant increased pressure for utilities, schools, improved streets and related local services. Inadequate local tax sources brought appeals for state assistance. Meanwhile the state and federal governments were looking to local governments to help administer new programs in public health, education, housing, urban redevelopment and other social services. Financial aid to local governments, therefore, expanded and principally took the form of grants subject to state or federal standards of performance and related supervision. The net result was not unlike the pattern that developed in England, although the confusion created by overlapping jurisdictions and special districts was not tackled with comparable vigour. The problem of federal-state-local relations, including the allocation of tax resources, remained a continuing one, and the subject of repeated studies by federal and state commissions.

Continental European Patterns of Centralized Control.—While England and the United States were struggling to adapt traditions of local autonomy and limited government to modern urban living, other countries were bringing local governments under strict national supervision. Adequate legal authority was provided by broad grants of power from the central government under general municipal laws. The administration of these powers, however, was held under much tighter central rein than in England or the U.S. France established a pattern of this type which had far-reaching influence in Europe, Latin America and Japan.

In France, the citizens elect a city council, which in turn selects a chief executive, the *maire*. Once selected, the latter becomes in many respects an official of the central government. He exercises extensive police powers independently of the council and is solely responsible for the conduct of city administration. His activities are, however, subject to close national supervision through the prefect of the *département*, or, in small towns, the subprefect of the *arrondissement*. The prefect may annul acts of a city council which conflict with national laws; he must approve the budget and numerous other kinds of local enactments; he may write into the budget any obligatory items which are omitted; and he may suspend the city council under certain conditions. After World War II the constitution of the fourth republic, adopted in 1946, set the stage for greater decentralization of local government in France by providing for the regrouping of jurisdictions, for greater powers to be retained by local councils and for clearer definition of national supervisory powers. The preoccupation of the fourth republic with national and international problems, however, often delayed carrying these principles into effect.

German cities first broke the feudalistic mould with the reforms of Baron vom und zum Stein in 1808, and between 1871 and World War I German municipal administration reached impressive heights of efficiency. Local councils were elected under restricted suffrage which gave one-third the council seats to a small group of large tax-payers, one-third to a group paying the next-highest taxes and only the remaining third to the mass of voters. This council selected an executive board (*Magistrat*) consisting in part of unpaid citizens, in part of salaried professionals. The chairman of this board was the *Bürgermeister*, a well-paid professional civil servant enjoying great prestige, authority and normally long tenure. This combination set a new standard in effective municipal administration. Although the *Bürgermeister* was subject to a series of higher authorities ending with the ministry of the interior, he had the authority and administrative competence necessary to good government. The Weimar republic democratized the councils, but made few basic changes in the structure of municipal government. The Hitler regime, on the other hand, altered the pattern drastically. The *Bürgermeister* and other principal local officials were named by the Nazi party delegate and wielded virtually all the powers of city government. After the Nazi col-

lapse in May 1945, local community elections led the return to self-governing institutions, and city elections were held throughout occupied Germany in 1946. Division of the country in the postwar years prevented the emergence of any consistent pattern of local administration.

Municipal government in Italy strongly suggests the French structure. Prior to Mussolini, centrally appointed prefects exercised extensive powers over local affairs in the provinces. The towns and villages (*comunes*) were governed by a locally elected council and mayor, known as the *sindaco*. Committees of the councils played a somewhat larger part in running local affairs than in France, but the detailed supervision by the prefects was comparable. In Italy, as in Germany, fascism brought extreme centralization under party control. Perhaps as a reaction, the Italian constitution of 1948 decentralized administration. New regional governments, each under a regionally elected council and centrally appointed commissioner, were given extensive powers to legislate for city matters. The principle that regions are normally to exercise their administrative functions by delegating them to the provinces and *comunes* or by using local officials was clearly intended to give municipal governments a new dignity and importance, while continuing to use them to carry out national and regional programs.

In Russia after the Communist Revolution the responsibility for local government became primarily that of the republics and regions. Quite a bit of variation exists. The basic pattern, however, vests general authority in a locally elected council (soviet), which in turn administers local affairs through its committees. In the larger cities the soviet selects a committee (presidium) to be the directing and co-ordinating executive. The party and youth organizations are active in selecting candidates, shaping policy and helping to carry out local programs. Popular participation in local government seems to be more active in the U.S.S.R. than it was under the fascist dictatorships of Germany and Italy.

In Latin American countries local administration has been strongly influenced by continental Europe. Regional administrative areas are commonly designated provinces or departments, and central controls over local affairs are frequently strong as in the French pattern. Constitutional provisions vary widely from extreme centralization to substantial local autonomy. The municipalities (*municipios*) in Latin America are not necessarily cities. They sometimes embrace sizable rural tracts around modest towns. The tendency, in general, is to treat the municipality as an administrative area for the national or regional government, and despite constitutional variations a high degree of centralized control over local affairs predominates.

Prior to World War II, Japan followed the continental system of centralized administration. German advisers after the Meiji restoration of 1868 helped shape the administration of local affairs, although the result was perhaps more French than German. This was encouraged by a basic step in the revolution itself which had replaced provincial feudal lords with centrally appointed governors. The powers of the prefectural governors largely obscured local governmental institutions. The Local Autonomy Law of 1947, however, drastically reversed the prewar pattern. Elected prefectural governors and assemblies were provided, while detailed provision was made for the government of cities, towns and villages. The law provided essentially self-governing status for "special cities" over 500,000, but the opposition of rural prefectures blocked putting this section of the law into effect. The government proceeded, however, with a vigorous program of amalgamating small towns and villages into larger entities capable of assuming important governmental functions. An elected mayor and assembly are the essential organs of local administration, with much of their time devoted to national and prefectural programs.

Major Trends in City Government.—The governments of the cities of the world show certain marked similarities and a number of common problems. A locally elected council is virtually universal. There is usually a single chief executive, and the trend has been to strengthen his administrative position. England and the U.S.S.R. are exceptions, with committees of the council playing a strong role in guiding professional department heads. The appointed professional chief executive, originating first in Germany, assumed major importance in the United States in the modern form of the city manager. Elsewhere in Europe and in Japan the elected local executive continued to predominate.

Central and state or regional governments came to rely increasingly on local governments for the administration of their programs. This was a natural development in the centralized continental systems, but it also became evident in Britain and the U.S. In both countries financial grants and technical supervision of services by higher authorities emerged as a definite pattern. In both countries, also, expanded services rendered local tax resources insufficient, even for traditional local services. Thus the tendency was to seek further financial aid, and with it to receive closer supervision. Meanwhile France, Italy and Japan were stressing decentralization. The trend, therefore, was toward removing some of the earlier distinctions between the traditional self-government of Anglo-U.S. cities and the more centralized continental systems.

Another distinct trend was the increasing professionalization of municipal services. Cities began to organize into national associations, such as the American Municipal association in the United States, and both national and international conferences of municipal officials became common. Likewise a growing number of specialists—city managers, finance officers, personnel officials, town planners, etc.—set up national and international professional associations.

A final trend to be noted was the growing concern over the problems of metropolitan areas. The great cities of the world do not fit into generalized local governmental patterns. They are sprawled out to engulf, socially and economically, areas far beyond their political jurisdictions. Many of them are the metropolitan hubs of their respective countries. This encouraged the consolidation of the larger metropolitan areas under distinctive governmental arrangements. London is governed principally by the Metropolitan county of London, embracing 29 metropolitan boroughs within a 100-sq.mi. area. The county has broad powers, which it administers under a county council of 124 members plus a 20-man board of aldermen chosen by the council. The Metropolitan police district and the ancient City of London (1 sq.mi.) are the principal exceptions to the county jurisdiction. Paris has an over-all municipal council of 90 members, but subdistricts of the city (*arrondissements*) are grouped into nine sectors each with its own mayor. Metropolitan Tokyo was consolidated into one large governmental district with prefectural powers in 1943. In 1953, Toronto, Ont., and 12 suburban municipalities were consolidated into one metropolitan district with authority to carry on a broad range of common functions.

Metropolitan government remained a major unsolved problem in the United States. After the five boroughs of New York city were consolidated in 1896, little progress in this direction was made. The Metropolitan district of Boston helped solve a few regional problems. But in general the central city, its satellite towns, and a variety of special districts remained a chaos of overlapping and competing jurisdictions. There is no metropolitan-wide authority competent to carry on the functions of planning, land-use control, transit, recreation, prevention of water and air pollution, and other activities that demand attention on an area basis. Because local jealousies and rivalries block the consolidation of metropolitan governments, it seems probable that only new kinds of multipurpose districts, able to carry on area-wide functions while leaving local matters to community determination, are likely to relieve the present unsatisfactory situation. Certainly the metropolitan region remains a major challenge to students of government throughout the world.

Additional information on city government may be found in the articles dealing with specific countries and some of the large cities.

CITY MANAGER. The city manager is the principal executive and administrative officer of a municipality under the council-manager form of local government, which spread widely in the United States and Canada after Dayton, O., became the first large city to adopt it in 1913.

Under the council-manager plan, the voters elect only the city council, which appoints a city manager to administer municipal affairs under its supervision.

The members of the council, usually five to nine in number, may be elected either at large or by wards. The mayor is a member of the council and serves as its presiding officer. He may either be designated to this position by the council or elected as such by the voters. The council acts only collectively, and its individual members, including the mayor, have no administrative functions.

The city manager serves at the pleasure of the city council. Subject to its general supervision, he is in full charge of the administration of municipal affairs. He prepares the budget, appoints and dismisses personnel and directs the work of the municipal departments. He attends all council meetings, presents recommendations on municipal business and usually takes an active part in the discussions.

Origin and Spread of Plan.—The council-manager plan was devised and first advocated in the U.S. by the National Short Ballot organization, an association which proposed to improve state and local government by reducing the number of elective offices in order to fix responsibility on a few officials. This organization, of which Woodrow Wilson was president and Richard S. Childs, a young New York advertising man, was the secretary and active promoter, undertook first to support the commission plan of municipal government. Under that plan, all municipal powers were vested in a commission, the members of which collectively served as a legislative body and individually administered the departments.

Since the dispersion of administrative functions proved to be a serious weakness of the commission plan, Childs's attention was attracted by the news that the city council of Staunton, Va., had appointed a general manager and delegated to him the function of directing the municipal departments. He seized on this idea as a means of overcoming the weakness of the commission plan, and the National Short Ballot organization formulated and began to promote the commission-manager plan, which in all essentials was the plan later known as the council-manager or city-manager plan.

Sumter, S.C., adopted the plan in 1912, and was followed by several other small cities. The greatest impetus to its spread came with its adoption in 1913 by Dayton, which had suffered a severe flood that required emergency action by its local authorities.

The National Municipal league, the principal organization in the United States for the promotion of municipal reform, had previously concentrated its efforts on strengthening the authority of the mayor and eliminating partisan patronage. After the early success of the council-manager plan, it adopted the plan in 1915 as the basis of its model charter for municipal governments. This charter added to the essential features of the council-manager plan provisions to establish a civil service system, to forbid members of the council to interfere with the city manager's administrative work or appointments and to forbid municipal employees to enagage in political activity. (About three-fourths of the cities that adopted the plan in the first half of the 20th century elected their councils at large.)

While it generally proved impractical to write into law a precise definition of the respective functions of the council and the city manager, in view of the fact that the city manager serves at the council's pleasure, the principal objectives of the plan were achieved in most of the cities that adopted it. The plan spread rapidly from 1918 to 1923, as many cities undertook programs of public works and municipal improvements and realized their need for more efficient administration.

The council-manager plan also grew rapidly after the end of World War II. During the years 1946 to 1954 inclusive, for example, 644 cities, representing an average annual gain of 71 cities, adopted the council-manager plan, and by Jan. 1955, it was in effect in 1,222 cities and 15 counties in the United States and Alaska and in 38 cities in Canada. Of the 481 cities in the United States with more than 25,000 population in 1954, 200, or 42%, operated under the council-manager plan; 33 of the 88 cities between 100,000 and 500,000 had the council-manager plan.

Legal and Political Basis.—The legal basis of the plan in the United States varies with state law. In states which permitted municipal home rule, cities established the plan by adopting by popular vote charters drafted by local reform groups, often following the model charter or the advice of expert consultants. Some adopted by popular vote an optional council-manager plan provided by state law. Some had their state legislatures enact special council-manager charters for them. And in others the city council adopted the plan by municipal ordinance without submitting it to popular vote.

The political circumstances under which the plan was adopted often affected the role of the city manager. Some cities, especially those in which the leaders in business affairs and civic organizations had never before taken part in municipal politics, adopted the plan as part of a vigorous campaign of municipal reform. Their purpose was to break the hold of partisan or factional organization on city government, and to eliminate patronage in jobs or contracts. In these cities the plan required the support of an active reform organization, and the plan itself and the city manager were likely to remain the subjects of political controversy.

At the other extreme, some cities in which the municipal leadership was generally respected adopted the plan on the initiative of their city councils, and the city manager was never identified with either side of a political contest.

Most cities were between these two extremes. In states where the national party organization did not take a direct part in municipal affairs (usually states in which one or another party was predominant) cities generally found it easier to get general acceptance for the council-manager plan and to establish the city manager as a noncontroversial career officer whose position was not at stake in elections.

Characteristics of Managers.—More city managers have had training or experience as engineers than in any other occupation. But following the end of World War II city councils preferred men with training and experience in public administration rather than men with specialized training. In 1954 one out of every five managers held graduate degrees in public or business administration or related fields, chiefly master's degrees. Of the managers in office in 1954, 82% had attended college and two-thirds of this group completed their college work.

While city managership had no definite training or entrance requirements, a young man who planned a career in this profession usually obtained a master's degree in public administration and served as an intern and as an assistant to a manager for several years before becoming a city manager. Forty-three per cent of the city managers appointed in 1954 were promoted from one city to another or were former managers who received new appointments. Nearly one-half of all managers came directly from other public administrative positions. Less than 10% of the managers came from nongovernmental positions. In 1954 three-fourths of all city-manager appointments were from outside the city as compared with 76% in 1953 and 58% for the ten-year period 1940 to 1949 inclusive.

City managers, with rare exceptions, refrained from taking part in local political campaigns, even when they were personally attacked by opposition factions. On the other hand, many took the lead in public discussions of municipal policy. Some of the most successful managers were extremely active as public speakers and as public advocates of improving or extending municipal services.

City managers looked on their work as a professional career, but at the same time they never expected to hold their positions except

at the pleasure of their city councils. Their professional society, the International City Managers' association, always took the position that the city manager was subject to dismissal by the council and refused to support proposals that he be removed only by more than a simple majority vote of council members. Similarly, it admitted to membership any city manager duly appointed by a city council and never sought to establish any criteria of its own for recognition or membership in the profession.

The association did a great deal not only to stimulate a professional attitude among its members, but also to advance the general level of municipal administration. It sponsored research in municipal administration; published the *Municipal Year Book*, an annual encyclopaedia of factual and statistical data on all cities in the United States; and conducted courses of training in various branches of municipal management.

The city-manager movement had effects beyond the sphere of municipal affairs. In the United States, city managers often went from municipal government into state and national administration and did much to help develop administrative systems in which federal, state and local agencies co-operate in the management of national programs.

See International City Managers' Association, *The Municipal Year Book* (published annually). (D. K. Pe.; C. E. Ry.)

CITY PLANNING: *see* Town and City Planning.

CIUDAD BOLÍVAR, an inland city and river port of Venezuela, capital of the state of Bolívar, on the right bank of the Orinoco river, 240 mi. above its mouth. Population (census of 1950) 31,054. The mean temperature is about 83° F.

The city stands upon a small hill some 125 ft. above sea level, and faces the river where it narrows to a width of less than half a mile. It is the commercial centre of the Orinoco basin, being the chief port both for imports to the inland of Venezuela and for exports from the country. Various air lines serve the city; there is regular steamship communication with the lower Orinoco, Port of Spain and the Caribbean coast of Venezuela. During the rainy season small steamers run far up the river. Several highways connect Ciudad Bolívar with the Venezuelan capital, Caracas, and with the coast.

The principal exports from this region include gold, cattle, horses, cacao, bitters, hides, timber and mineral ores. There are large gold mines southeast of the city, and bauxite and iron deposits to the south and southwest.

The town was founded by Mendoza in 1764 as San Tomás de la Nueva Guayana, but its location at this particular point on the river gave to it the popular name of *Angostura*, the Spanish term for "narrows." Angostura bitters were invented there in 1824, although the manufacture was thereafter transferred to another city. The name Angostura was used until 1849 when that of the Venezuelan liberator was bestowed on it. Ciudad Bolívar played an important part in the struggle for independence and was for a time the headquarters of the revolution.

The town suffered severely in the fight for its possession, and the political disorders which followed greatly retarded its growth. (C. E. Mc.)

CIUDAD JUAREZ, formerly El Paso del Norte, a northern frontier town of Mexico, in the state of Chihuahua, 1,223 mi. by rail N.N.W. of Mexico City. Pop. (1910) 10,621; (1950) 128,782. Ciudad Juárez stands 3,800 ft. above sea level on the right bank of the Rio Grande del Norte, opposite the city of El Paso, Tex., with which it is connected by bridges. It is the northern terminus of the Mexican National railway and has a large transit trade with the United States, having a customhouse and a United States consulate. It is also a military post with a small garrison. The town has a straggling picturesque appearance, a considerable part of the habitations being small adobe or brick cabins.

Ciudad Juárez was founded in 1681–82; its present importance is due entirely to its position on the border and the railway into the interior. It was the headquarters of Pres. Benito Juárez in 1865 and was renamed in 1885 because of its devotion to his cause.

CIUDAD REAL, a province of central Spain, formed in 1833 of districts taken from New Castile and bounded on the north by Toledo, northeast by Cuenca, east by Albacete, south by Jaén and Cordova and west by Badajoz. Population (1950) 567,027; area, 7,622 sq.mi.; density per square mile 75.0. In the east and centre are extensive high plains forming part of the region known as La Mancha and rising on the southeast to low hills. The west consists of broken hilly country bordered on the south by the parallel ridges of the Sierra de Alcudia and by the Sierra Madrona, foreranges of the Sierra Morena. The province is drained, except on the southeast, by the Guadiana river which traverses it from east to west and receives several tributaries, notably the Gigüela, Záncara and Bullaque on the right and the Azuel and Jabalón on the left.

The climate on the plains is oppressively hot in summer, and in winter bitterly cold winds prevail. The rainfall is scanty and prolonged droughts are common. Forests occur only on the higher ground in the west. The vegetation on the La Mancha plains is limited to poor pasture. Cereals, saffron, the olive and vine are cultivated, but agricultural development is hindered by the scantiness of the population, the aridity and poverty of the soil, the want of proper irrigation and the occasional ravages of locusts. Large numbers of sheep and goats, however, are reared on the plains, and Ciudad Real is famous for its mules. Pigs are kept in the oak forests of the west, and cork is an important product of this region.

Coal is mined round Puertollano, lead in various districts and important mercury deposits at Almadén. There is no other industrial development.

The roads are insufficient and ill-kept, especially in the northwest, where they form the sole means of communication. The Madrid-Lisbon railway passes through the capital, Ciudad Real, and through Puertollano, where there is a branch line to San Quintin. Farther east, the Madrid-Linares railway passes through Alcázar de San Juan, junction for the Albacete line, and Manzanares and Valdepeñas, where branch lines link it with Ciudad Real and Puertollano respectively. There is also a branch in the northeast to Tomelloso.

The capital is Ciudad Real (pop. 1950, 34,244 mun.) (*q.v.*). The principal towns, with 1950 population of *municipios* are: Valdepeñas (26,020), Tomelloso (30,072), Puertollano (34,884), Alcázar de San Juan (25,139), Manzanares (18,204); Almodóvar del Campo (14,719) and Almadén (12,375). Almagro (9,949), famous for its lace, and Daimiel (20,204), a market centre of La Mancha and site of a military aerodrome, belonged in the middle ages to the knightly order of Calatrava, formed in 1158 to keep the Moors in check. Campo de Criptana (15,659) and La Solana (14,699) are other market towns. Education is very backward. (*See* also Castile.)

CIUDAD REAL, a town of central Spain, capital formerly of La Mancha and after 1833 of the province described above. It lies 107 mi. S. of Madrid, on the Madrid-Badajoz-Lisbon and Ciudad Real-Manzanares railways. Pop. (1950) 34,244 (mun.). Ciudad Real, situated on a wide plain, between the river Guadiana in the north and its tributary the Jabalón on the south, offers little of interest beyond its lofty Gothic cathedral, built without aisles. It is the market for the cereals, oil, wine, potatoes and figs produced with irrigation on the surrounding plain. Ciudad Real was founded by Alphonso X of Castile (1252–84) and fortified by him as a check upon the Moorish power. Its original name of Villarreal was changed to Ciudad Real by John VI in 1420. It is said to have suffered greatly, especially in the loss of its flourishing leather industry, by the expulsion of the Moriscos in the 17th century.

During the Peninsular War a Spanish force was defeated there by the French, on March 27, 1809.

CIUDAD RODRIGO, a town of western Spain, in the province of Salamanca. It is situated on an eminence on the right bank of the river Agueda, 13½ mi. E. of the Portuguese frontier, and on the railway from Salamanca to Coimbra in Portugal. Pop. (1950) 12,596 (mun.). Ciudad Rodrigo is an episcopal see and was for many centuries an important frontier fortress. It was founded

in the 12th century by Count Rodrigo González and named after him, but remnants of a Roman aqueduct and bridge indicate that it occupies the site of a Roman settlement. The 12th-century cathedral, with fine cloisters and carved portico, was disfigured by additions in 1538 and has suffered during sieges from its position almost astride the walls. During the Peninsular War, it was captured by the French under Marshal Ney, in 1810; but on Jan. 19, 1812, it was retaken by the British under Viscount Wellington, who, for this exploit, was created earl of Wellington, duke of Ciudad Rodrigo, and marquess of Torres Vedras, in Portugal. (X.)

Siege of Ciudad Rodrigo, 1812.—For the operations preceding and following the siege of Ciudad Rodrigo in 1812 *see* PENINSULAR WAR. Having insufficient troops to provide a covering force Wellington decided to use the element of surprise. He waited till both armies were scattered in winter quarters, made all his preparations in secret, and then suddenly, on Jan. 8, appeared before the town. Ciudad Rodrigo lies on the right bank of the Agueda and in 1812 its fortifications were modern and formidable, but it was commanded on the north by a hill, the Great Teson, which, crowned by a strong redoubt, rose to a height of 150 ft., only 600 yd. from the walls. Between this hill and the town lay a slightly lower ridge, the Little Teson, which was flanked at its eastern end by the convent of San Francisco, at its western by that of Santa Cruz. The very night of his arrival Wellington stormed the redoubt on the Great Teson and at once began his preparations for an intensive siege. The weather was terribly severe, so that the troops in the trenches had to be relieved every 24 hours, but the men worked with great speed and enthusiasm. Within six days the British had dug a parallel and constructed batteries for 32 guns on the Great Teson, had sapped across the low ground and dug a parallel within assaulting distance on the Little Teson, and had stormed the convents which flanked it. For five days a furious bombardment was maintained, the enemy replying with equal vigour. By Jan. 19 two breaches had been made in the walls and, though the counterscarp had not been destroyed nor the enemy's guns silenced, Wellington gave orders for an assault. The main breach, at the northern corner of the fortifications was to be stormed by the 3rd division; the lesser breach, 200 yd. to the east, by the light division. Pack's Portuguese were to make a feint attack upon the San Pelayo gate at the other side of the town. At 7 P.M. on the 19th Campbell's brigade of the 3rd division entered the ditch at the southwest corner of the fortress, with orders to scale the outer wall and clear the left flank of the main breach. Their actual entry was premature and the garrison opened fire while the other attacking troops were still in their assembly trenches. The storming columns at once dashed forward. The 3rd division was checked at the main breach by a land mine, but quickly drive the defenders back to a retrenchment behind the breach, which for a time held them back. The light division met with less opposition and, pouring through the lesser breach, cleared the way for their comrades on the right. The garrison quickly surrendered, but the storming troops got out of hand and for the rest of the night plundered, drank, burned and murdered; only at daylight was order restored. The siege cost Wellington 1,000 casualties, half in the assault, but 1,500 prisoners and 150 guns fell into his hands. Marmont only received definite news of the siege on the 15th; by the time he had collected his army the town had fallen. (H. L. A.-F.)

CIUDAD TRUJILLO (SANTO DOMINGO), capital of the Dominican Republic on the island of Hispaniola. Pop. (1950 census) 181,553. It is on the south coast, on the river Ozama. Founded in 1496, it is the oldest existing settlement of white men in the New World, and perhaps the most perfect example of a Spanish colonial town of the 16th century. It is surrounded by ancient walls with bastions. The streets are straight, narrow and intersect at right angles. The massive houses are built of stone with coloured walls pierced with huge doors and windows. The cathedral, in the Spanish Renaissance style, dates from 1512, and contains the reputed tomb of Columbus (*q.v.*). The cell in which he and his brother were confined by order of Bobadilla is still shown in the old fortress. The city is the seat of an archbishop. It has a small harbour, but the river is navigable for 4 mi. from its mouth.

CIUDAD VIEJA, a highland village of Guatemala about 22 miles S.W. of Guatemala city and 3 mi. S.E. of Antigua, situated in the valley of the Almolonga at the foot of the volcano *Agua* (water). Urban population of the *municipio* of Ciudad Vieja (1950 census), 5,415. Originally named Santiago de los Caballeros de Guatemala, the city was founded in 1527 under the direction of Jorge de Alvarado, brother of Pedro de Alvarado, conqueror of Guatemala, and became the third capital of the Spanish Captain Generalcy of Guatemala. (The first and second capitals were, respectively, Iximché and Xepau.) News of Pedro de Alvarado's death in Mexico reached Ciudad Vieja on Aug. 29, 1541; on Sept. 8 his widow, Beatriz de la Cueva, had herself decreed governor of the province. Either as the result of a storm or an earthquake which cracked open the crater of the volcano *Agua*, an avalanche of mud and water descended upon the city on Sept. 10, burying, among several hundred other people, Doña Beatriz. Following this disaster, the capital was moved to Antigua, whence it was in turn removed, because of an earthquake in 1773, to the present site of Guatemala (*q.v.*).

CIVERCHIO, VINCENZO, an early 16th century Italian painter, born at Crema. There are altar pieces by him at Brescia, and at Crema the altar piece at the duomo (1509) is his work. His "Birth of Christ" is in the Brera, Milan; and at Lovere are other of his works dating from 1539 and 1540.

CIVET, or, properly, CIVET CAT, the name given to the more typical members of the Viverridae (*see* CARNIVORA), which are characterized by the presence of a deep pouch near the genital organs into which a fatty, yellowish substance, known as civet and having a strong musky odour, is secreted. Several species are known. The African civet (*Civettictis civetta*) measures 3–4½ ft. in length, of which a third is tail, and stands 10–12 in. high. The hair is long, forming an erectile ridge down the middle of the back; in colour it is dark grey with black bands and spots. The animal is nocturnal and largely carnivorous; it climbs trees with agility. It is kept in captivity (where, however, it never becomes tame) for its perfume, the larger quantity of which comes from the male and is scraped from the pouch with a spoon twice a week. The zibeth (*Viverra zibetha*) extends from Arabia to India and several East Indian islands. Other species occur in India, China and Malaya. The odorous principle (a ketone) has been isolated and named civetone. Civet is used for blending scents.

CIVET, A CATLIKE ANIMAL, VALUED FOR A GLANDULAR SECRETION USED FOR PERFUME

CIVICS. Civics owes its origin to the Latin *civicus*, meaning citizen. Hence, broadly interpreted, it refers to the mutual relationships which obtain between citizens in the state and in society in general. The concern of the school with these relationships finds one of its chief expressions through the social study known as civics.

Although civics seldom appears in the elementary school as a separate subject, beginning about 1910 increasing attention was paid in the first six or seven years of instruction to the cultivation of such civic attitudes as respect for authority, fair play, tolerance of the views of others and an understanding of the interdependent nature of personal relations. Courses in civics identified as such appear throughout the secondary school with the greatest concentration in the 9th and 12th years. Such courses appear under a variety of titles such as vocational civics, economic civics, social civics, citizenship, problems of democracy, community civics and many others. While the variety of titles reflects some indecision as to what civics is, it nevertheless reports a conception of citizenship far more realistic than that which was commonly employed as recently as 1915 and elaborated under the title of government or civil government.

The changes which occurred in the conception and teaching of civics following World War I were greater than in any other social

study. These changes are clearly related to and have been roughly concurrent with the dramatic changes that characterize the recent history of western society—the increasing speed of the transition from the police to the service state, the multiplication and improvement of mass media of communication, the increasingly industrial, urban, and rational nature of social life, the growing interdependence of its parts and the consequent need to examine critically the adequacy of cultural, economic and political institutions devised as instruments of social control in a much simpler world.

The older civics was, for the most part, the study of the forms of political organization, requiring chiefly rote learning. Modern civics is the study of the dynamic processes in which representative groups, both voluntary and nonvoluntary, reach working agreements as to their goals, and shape, and continually reshape, the instruments for their realization.

In those courses which represent the best thought and practice, many types of human association are studied. These range from the family, the play group, the school team and youth service organizations to the trade union, the corporation and civil communities. These civil communities vary in size and complexity from the neighbourhood, village, city, county and commonwealth to the nation and such emerging units as the metropolitan area and the nascent society of nations. In these various groups contexts, as befits the maturity of the student, such matters as the following are studied: the relation of the individual to others in group life, the nature and importance of discussion in the development of democratic consensus, the process of group formation and cohesion, and the relation between implemental and goal values.

The comprehensive view which civics takes of citizenship requires that it study the process of governing in the context of realistic cultural and economic situations. Furthermore, in these contexts, governing is viewed both in the formal-constitutional and in the informal-voluntary-group sense. Such cultural and economic considerations as the conditions of employment, the incidence of amount and regularity of income with mental and physical security, the distribution of medical, dental and hospital services, the prevention and treatment of crime, the conservation of natural resources, the quality and quantity of the human population and allied topics provide fertile soil for the study of the meaning of terms which, lacking such treatment, are mere slogans. Put now in their proper context, such terms as freedom, equality and justice identify the conditions under which the struggle for democracy goes on, offer abundant illustrations of both formal and informal political controls and, in short, provide the setting for the study of *Realpolitik*. They likewise serve as practical and vital points of departure from which to study and appraise the adequacy of the executive, legislative, judicial and administrative agencies of government in the formal sense.

The modern conception of the nature of civics is, however, attended by significant difficulties. There is first the fact that political problems are by definition moral problems and hence are less susceptible of being treated with the finality and precision possible in, for example, languages, mathematics and the natural sciences. Closely related is the fact that the teaching of civics in a democratic society involves the dual and seemingly paradoxical task of fostering both loyal and critical attitudes. Furthermore, it falls especially to civics to expose fallacious views held by many earnest but confused persons, such as the belief that one conception of the nature of democracy is quite as reliable as another—irrespective of knowledge of its ideals and the adequacy and relevance of the means employed to realize them.

Only when taught in the context of the opportunities which present-day democracy affords and the difficulties which attend such an inquiry, can civics, in common with cognate social studies, develop rationally grounded democratic attitudes and permit the student to acquire basic intellectual skills. These objectives can be realized only within the framework of substantial knowledge about, and, in so far as possible, personal acquaintance with, democracy in process.

CIVIDALE DEL FRIULI, a town of Venetia, Italy, province of Udine, 10 mi. E. by N. by rail from the town of Udine; 453 ft. above sea-level; it was the ancient Forum Iulii. Pop. (1951) 11,454 (commune). The river Natisone forms a picturesque ravine here. The cathedral of the 15th century contains an octagonal marble canopy with sculptures in relief, with a font below it belonging to the 8th century. The museum contains Roman and Lombard antiquities, mss. and gold, silver and ivory objects formerly belonging to the chapter. The small church of S. Maria in Valle belongs to the 8th century, and contains fine decorations in stucco probably of the 12th century. The fine 15th-century Ponte del Diavolo leads to the church of S. Martino, which contains an altar of the 8th century with reliefs executed by order of the Lombard king, Ratchis. At Cividale was born Paulus Diaconus, the historian of the Lombards in the time of Charlemagne. A railway runs to Caporetto (16m.).

The Roman town of Forum Iulii was founded either by Julius Caesar or by Augustus, when the Via Iulia Augusta was built through Utina (Udine) on its way north. After the decay of Aquileia and Iulium Carnicum (Zuglio) it became the chief town of the district of Friuli and gave its name to it. The patriarchs of Aquileia resided here from 773 to 1031, then returned to Aquileia, and finally in 1238 removed to Udine. This last change of residence was the origin of antagonism between Cividale and Udine, terminated by their surrender to Venice in 1419 and 1420 respectively.

See G. Fogolari, *Cividale del Friuli* (Bergamo, 1906), well illustrated; *Memorie Storiche Forogiuliesi, passim* (Udine, 1905, *sqq.*—in progress).

CIVIL ENGINEER. When, in the 18th century, attention began to be given in England to such works of public value as roads, canals, harbours, docks, and lighthouses, the regulation of rivers, the production of iron by improved methods, and the construction of steam engines and of the machinery called forth by that new source of motive power, there arose men of great natural gifts, either with little technical training but great practical intelligence and skill, such as Brindley, or of equal practical capacity coupled with scientific attainments, such as Smeaton and Watt. These men applied to beneficent purposes the mechanical and constructional arts which previously had formed almost entirely the vocation of the military engineer, and they called themselves "engineers"; but Smeaton, seeing the inappropriateness of assuming a title hitherto belonging to military men, adopted the title "civil engineer," to make it clear that he was a civilian practitioner of those arts.

It was with this conception of the civil engineering profession that the Institution of Civil Engineers was founded. A royal charter of incorporation was granted to the institution on June 3, 1828. Before applying for the charter, the Society drew up a definition of the profession, "the art of directing the great sources of power in Nature for the use and convenience of man."

Many societies have since arisen having for their object the advancement of particular branches of engineering work, but the institution adheres to the conception of civil engineering held by its founders, and admits to its ranks any engineer who is adequately trained and experienced in the design and execution of any works or machinery instrumental in the application of sources of power for the benefit and convenience of mankind. The roll of the institution in 1928 numbered upwards of 10,000. Its house in Great George street, Westminster (the third building which it has occupied in that street), was built in 1912–13.

Specialization has brought about separate grouping of those interested in mechanical, electrical mining, etc., engineering. Underlying all groups is the work of the civil engineer, whose field particularly is that of structures. Foundations, simple or extremely complicated, are within his realm. He designs and supervises the construction of bridges and great buildings, tunnels, dams, reservoirs and aqueducts; he brings water to the centres of population and disposes of their wastes. He irrigates the desert and reclaims the swamps. He lays out, constructs and maintains highways and railroads, digs canals, regulates rivers, deepens harbours, builds lighthouses and constructs wharves and piers. He measures the earth's surface and the objects on it, and charts the resulting data. The work is frequently of a very definitely pioneering character, involving protracted physical effort. The civil engineer must have a scientific attitude of mind, and should

have imagination, initiative, accuracy and good judgment, trained by special study. He should be able to work with men as well as with materials, and he should have administrative ability. In the United States with over 100 million inhabitants, probably 75,000 persons would call themselves civil engineers.

The American Society of Civil Engineers, founded in 1852, admits engineers from various fields. It has a membership of about 14,000 and is an important engineering institution.

CIVILIS, CLAUDIUS, or more correctly IULIUS, a Batavian leader of the German revolt against Rome (A.D. 69–70). He had served as a Roman auxiliary. During the disturbances that followed the death of Nero, he induced the Batavi to rebel, under the pretence of assisting Vespasian. The neighbouring Germans joined the revolt. The Roman garrisons near the Rhine were driven out, and 24 ships captured. Two legions were blockaded in Castra Vetera (near the modern Xanten), and the survivors were finally massacred. Eight cohorts of Batavian veterans joined their countrymen, and the troops sent by Vespasian to the relief of Vetera threw in their lot with them. The result of these accessions to the forces of Civilis was a rising in Gaul. The Roman generals were murdered (A.D. 70), and the whole of the Roman forces were induced by two commanders of the Gallic auxiliaries (Julius Classicus and Julius Tutor) to revolt from Rome and join Civilis. Most of Gaul declared itself independent, and the foundation of an empire of the Gauls was contemplated. Vespasian resolved to take strong measures for the suppression of the revolt. The arrival of Petillius Cerialis with a strong force awed the Gauls and mutinous troops into submission; Civilis was defeated at Augusta Treverorum (Trier, Trèves) and Vetera, and forced to withdraw to the island of the Batavians. He finally came to an agreement with Cerialis whereby his countrymen obtained certain advantages, and resumed amicable relations with Rome. From this time Civilis disappears from history.

BIBLIOGRAPHY.—The chief authority for the history of the insurrection is Tacitus, *Histories*, iv., v., whose account breaks off at the beginning of Civilis's speech to Cerialis; also Josephus, *Bellum Judaicum*, vii. 4. Henderson, *Civil War and Rebellion in the Roman Empire* (1908); Mommsen, *Provinces of the Roman Empire* (ch. iv.), trans. Dickson (1909).

CIVILIZATION. This Encyclopædia is in itself a description of civilization, for it contains the story of human achievement in all its bewildering developments. It shows what men during hundreds of thousands of years have been learning about themselves, their world and the creatures which share it with them. They have reached out into remote space and studied nebulae whose light reaches them after a million years; they have, on the other hand, dissected atoms and manipulated electrons as they might handle pebbles. In the present magnificent series of volumes man's inventions are reviewed from the rudest chipped flint to the most delicately adjusted microscope; his creation of multiform beauties of design, colour and word, his ways of dealing with his fellows, his co-operations and dissensions; his ideals and lofty aspirations, his inevitable blunders and disappointments; in short, all his gropings, disheartening failures and unbelievable triumphs are recalled.

Several thousand contributors have been brought together to do each his special part in writing some thirty-five million words on what mankind has hitherto done and said. It might therefore seem at first sight superfluous, and indeed impossible, to treat civilization itself as a separate topic in a few pages. But there is danger that owing to the overwhelming mass of information given in these volumes certain important underlying considerations may be lost sight of. There are highly significant questions concerning the nature and course of human development, the obstacles which have lain in the way of advance; the sources of success and frustration, which could hardly be brought together in dealing with any of the special aspects of human culture. Accordingly an attempt will be made under this caption to scan civilization as a single, unique and astonishing achievement of the human species.

To begin with, it is a startling fact that civilization, which sets off man in so astounding a manner from all other animals, should only lately have begun to be understood. We are immersed in it from infancy; we take it for granted, and are too near it to see it, except in this detail and that. Even to-day, with all our recently acquired knowledge, those who strive most valiantly in imagination to get outside civilization so that they may look upon it dispassionately and appraise it as a whole, are bewildered by its mysteries. As for the great mass of intelligent people, they still harbour many ancient illusions and misapprehensions from which they can only be weaned with great reluctance.

The object of the present article is to describe the newer ways of viewing civilization, its general nature, origin, progress, transmission and chief developments, in the light of information which has been accumulating during the past fifty or sixty years. The study of man himself has been revealing quite as many revolutionary facts and hypotheses during the past half century as the scientific investigation of the world in which he lives. The history of human achievement has been traced back, at least in vague outline, hundreds of thousands of years; man's original uncivilized nature and equipment have been studied and compared with the behaviour of his nearer relatives; new conjectures have emerged in regard to the functioning of speech and the nature and origin of human reasoning; careful investigations of primitive civilizations have cast great light on more complicated ones; the tremendous importance of childhood and its various implications in the development of civilization have been elaborated.

These and many other discoveries conspire to recast our conception of civilization, its past progress and its future possibilities.

It is instructive to note that the word civilization is by no means an old one. Boswell reports that he urged Dr. Johnson to insert the term in his dictionary in 1772, but Johnson refused. He preferred the older word "civility." This, like "urbanity," reflects the contempt of the townsman for the rustic or barbarian; it is an invidious term, although in a way justified by the fact that only where cities have grown up have men developed intricate civilizations. The arduous and dispersed tasks of the hunter, shepherd and peasant folk do not afford the leisure, or at least the varied human contacts, essential to the generation of new ideas and discoveries. But modern anthropologists have pointed out that peoples without cities, such as the tribes of Polynesia and the North American Indians, are really highly "civilized," in the sense that upon sympathetic examination, they are found to have subtle languages, ingenious arts, admirably suited to their conditions, developed institutions, social and political; religious practices and confident myths, no better and no worse substantiated than many that prevail to-day among the nations of Europe. All these betoken and presuppose a vastly long development. Among English speaking people the first to point this out clearly was E. B. Tylor, who published his famous *Primitive Culture* in 1871, the same year in which Darwin's *Descent of Man* appeared. These two books would alone have served, by different approaches, to give the word civilization a far more profound meaning than it had ever had before.

NEW CONCEPTION OF CIVILIZATION

There could be no real understanding of the fundamental characteristics of civilization until the fact was well established and digested that could we trace back man's lineage far enough we should find it merging into that of wild animals, without artificial shelters, clothes or speech; dependent for sustenance on the precarious daily search for food. It requires a considerable effort of the imagination to picture the human race without these seeming necessities of even primitive civilization. Without fire and tools men must have existed as did a wild girl discovered near Châlons, France, in 1731. She possessed a monkey-like agility which enabled her to catch birds and rabbits; these she skinned with her nails and gobbled raw, as would a dog. She delighted to suck the blood from living pigeons, and had no speech except hideous screams and howls.

This conception of man's former animal existence is gradually supplanting the older one, based upon ancient Hebrew tradition, that the first man and first woman were special creations with fully developed minds, speech and reason, which enabled them forthwith to dress the garden in which they found themselves, to

name its animal denizens, and to talk with one another, and with God himself in the cool of the evening. This view is still passively accepted by an overwhelming majority of Americans and Europeans and is at present hotly defended by a powerful group in the United States.

The former assumption was that man was *by nature* endowed with a *mind* and with *reason*. These distinguished him sharply from the animals, which did wondrous things it is true, but not as a result of reason. Their behaviour was guided, it was argued, by instinct. Darwin says that "the very essence of an instinct is that it is followed independently of reason." But if we agree, as manifold evidence seems to force us to do, that long, long ago men behaved and lived like wild animals, are we not forced to ask if they did not live wholly according to what Darwin calls "instincts"? And if once upon a time our ancestors lived solely by their animal equipment, did they as yet have a mind and reason? May not the human mind be something that has very gradually developed as a result of man's peculiar animal make-up and capacities? May not his reason be but another name for his slowly accumulated knowledge and beliefs and his ways of dealing with them and building upon them? In any case the discovery that our ancestors once lived like wild animals raises entirely new and difficult questions as to the nature, origin and interpretation of those powers of his known as mind and reason, which have enabled him to seek out those inventions and come upon beliefs and practices which have produced in the aggregate civilization.

In short, it seems to be more and more apparent that mind and reason were not part of man's original equipment, as are his arms and legs, his brain and tongue, but have been slowly acquired and painfully built up. They are themselves *inventions*—things he has come upon. Like other inventions *they are part and parcel of civilization*—not innate in man but dependent for their perpetuation on education in the widest sense of that term. This is so novel an idea that many readers may find it difficult to grasp, but when grasped it alters one's whole estimate of human progress. We ordinarily think of civilization as made up of mechanical devices, books and pictures, enlightened religious ideas, handsome buildings, polite conduct, scientific and philosophical knowledge, social and political institutions, ingenious methods of transportation and the rest. We think that all these things are due to man's possession of a mind, which no animal has, and as a result of the exercise of reason. In a way this is true enough, only we must reconceive mind and reason and regard them just as truly a part of the gradual elaboration of civilization as a House of Commons or a motor car, and quite as subject to improvement. At the risk of making a seemingly irrelevant philosophical digression, which is really most essential to a modern understanding of civilization, something may be said of the newer conception of mind and its variant, reason.

The word mind was originally a verb, not a noun; it meant action, not a thing or agent. It was remembering and purposing, and taking note of—as for instance "I minded"—that is, remembered, or paid attention to, or was concerned by. But as time went on philosophers made a noun of the good old verb. It was conceived as that incorporeal substance which was the seat of a person's consciousness, thoughts, feelings, and especially of his reasoning. The body was set over against the mind whose orders it was supposed to execute. The Scottish philosopher of common sense, Reid, says explicitly that "we do not give the name of mind to thought, reason or desire; but to that power which both perceives and wills." Even John Stuart Mill says in his *Logic* that "mind is the mysterious something which feels and thinks."

Recently there has been a tendency to reduce the noun mind once more to a series of verbs—desiring, remembering, feeling, thinking, distinguishing, inferring, planning—and to regard the assumption of "a mysterious something" as unfounded, unnecessary and a serious embarrassment. Relieved of this embarrassment it is possible to begin to bridge the gulf between the original behaviour of the human race and that of mankind to-day. Descartes and all the older philosophers believed that man had always had a mind as good as theirs. They sought to tell him how to employ it in the pursuit of truth. Mind was to them a sort of divine instrument, conferred solely upon man, that could be sharpened and efficiently used by following the laws of logic; but they could not think of it as something accumulated, so to speak, through the many thousands of years since man made his first contributions to the upbuilding of civilization.

The way is now cleared for a new view of civilization which would not have been possible 50 or 60 years ago. Civilization is no longer contrasted with "rusticity," "barbarity" or "savagery," but with man's purely animal heritage. Modern men are still animals, they have to eat and sleep, protect themselves from the inclemencies of the weather, and defend themselves from attacks of their fellow creatures and other animals, and to rear a new generation, if the species is to be perpetuated. They closely resemble kindred animals in much of their physical structure, in their important organs, breathing, digestion and the circulation of their blood. All these peculiarities are hereditarily transmitted no matter how much or how little men may be civilized. On the other hand, civilization—language, religion, beliefs, morals, arts and manifestations of the human mind and reason—none of these can be shown to be handed down as biological traits. They can only be transmitted to a new generation by imitation or instruction.

All mankind to-day has a double heritage. The one comes to us without any effort on our part, as do the spider's peculiar characteristics or those of birds, or of any of our fellow mammals; come to them. It is secure and tends to remain the same for thousands of years. Civilization, on the other hand, is precarious; it must be assimilated anew by each one of us for himself in such a degree as circumstances permit. It can increase indefinitely but it may also fall off tremendously, as the history of man amply testifies. It is a legacy that can be lost as well as kept and increased.

To illustrate: it may be that before human beings had acquired any of this loseable thing, civilization, they would pick up a stick to strike an assailant or hurl a stone at him. They might have found themselves riding astride floating tree trunks to cross a stream. Certain persons would occur, let us say, in each generation who would do all these things without ever having seen them done. These acts would be classed in man's animal heritage. But should we find traces of men who chipped a flint nodule into a hatchet head, and hollowed out their log with such a hatchet, or with fire, we should have to class these acts among the arts of civilization since they presuppose so much accumulated experience and ingenuity that they could not be inborn. The art of making a rude boat might consequently be wholly lost, as surely many inventions must have lapsed, if a single generation passed without constructing one.

It seems now an imperative fact that all civilization—the total social and traditional heritage, would fall away immediately and completely should a thoroughgoing forgetfulness, an overwhelming amnesia and profound oblivion overtake humanity. Only their natural equipment would be left. As Graham Wallas suggests, those least civilized would have a possible chance of surviving. It is only uncivilized man that might go on indefinitely. We are all by nature wild animals *plus;* and our taming weakens us for the ancient struggle in the forest, naked and bare-handed.

PECULIAR ITEMS OF MAN'S BODILY FORM

At this juncture the question arises, what was there peculiar in man's physical make-up that enabled him to initiate civilization and build up a mind which he could use to increase his resources so far beyond that of any other animal? Before proceeding we should recollect that the ways of all living creatures are manifold and astonishing. Even a single-celled organism can marvellously adjust itself to altered conditions. It seems to learn by experience, it appears to have a sort of memory, it is modified by happenings which interrupt its comfortable routine. It is ingenious in defending itself, in seeking food and reproducing. It is, in short, purposive in its conduct. The tiger and the frog are able to adjust themselves to very different modes of life, and so are the orioles and cacti. Before man began to accumulate civilization we are forced to assume that he too made terms with the

daily need of adjustment which faced him, otherwise we should not be here to write the tale. These are the salient essentials of *Life*, and man is a part of what Julian Huxley calls "the stream of life." All these possibilities lay behind the development of man's intelligence. They are the hinterland from which civilization emerged and to which it ever tends to retreat.

In order to begin and carry on the accumulation of civilization, man had of necessity to be so constructed physically that he could *perceive* more clearly than his predecessors, make more accurate distinctions and so remember and imagine better; for all these are essential to talking and thinking. The awareness of animals is of a low, vague type, and so must pristine man's have been. The one-celled animals behave in a purposive way, but they have no eyes or ears or noses. They must live in silence and darkness like a human blind, deaf mute. They will nevertheless take in certain food and reject other things. They perceive and act without, so far as we can see, being conscious of their actions. They make the necessary decisions without deciding in a human sense. They have no nervous system, but, as has lately been discovered, the promise of one. The creatures most like ourselves have eyes, ears and noses, and evidently see, hear and smell; and they have an elaborate nervous system. Of these resources they make constant use. But compared with man they are ill-qualified to make careful distinctions and discriminations and remember clearly. They take note of far fewer factors in their situation. They must act somewhat as our digestive system does. It is a sort of animal within us which performs wondrous feats when given food. It works purposively, as does our heart and blood circulation. We can become *conscious* of these unconscious achievements when we choke, because the switch is not thrown promptly enough to prevent a morsel from going down our windpipe instead of taking the route to the stomach. Palpitation of the heart is a conscious suggestion of the faithful pump, which rarely reminds us of its constant attention to business. Let it neglect two or three beats and we are dead.

The essentials of man's physical equipment for initiating and piling up civilization have been dwelt upon by many writers. He has sensitive hands, and (after he got securely on his hind legs) he could use them far more freely than if he had to employ them as auxiliary feet. His thumb can be readily placed against any one of his fingers. There is no such expert feeler and handler as he to be found among his kindred. He could learn much of shape and form, of softness and hardness, of weight, texture, heat and cold, toughness, rigidity and flexibility, which could be but vaguely sensed with hoof or paw. Had he had ears that he could turn about like a jack-rabbit, and a prehensile tail, he might have been able to learn faster. And all these things were the beginning of knowledge. He could not only strike but hurl. His eyes were so placed that he was always looking through a stereoscope, so to speak, and seeing things in the round. His vocal organs promised a great range of delicate discrimination in the sounds he made. Then he was a helpless dependent for many years on his elders so that their acquired ways could become his.

Lastly there is man's brain with its complex cerebral cortex and its association paths, which develop astonishingly as a child grows up. The cortex is the prime correlator of impressions, and is modified through individual experience in a higher degree than any other part of the nervous system. Its functioning is still very mysterious, but no one doubts its essential rôle in the process of human learning and the increase of intelligence. Its operations are not, however, autonomous but closely associated with the experiences of the whole human organism and dependent on those singular capacities of mankind already mentioned.

So it becomes apparent that after hundreds of millions of years during which nature's experiments have been going on in physical structure and function, which have enabled creatures of the most diverse types to meet the absolute requisites of life—growing up and reproducing their species—a kind of animal finally appeared on the earth so constructed that he could become civilized. Man's biological make-up represents a unique combination of physical characteristics. Most of these, as we have seen, occur in other mammals. Even those which seem peculiar to him would not serve, however, as a foundation for the development of civilization except in a highly complex union. Cows might have a human cerebral cortex, foxes apposable thumbs, birds stereoscopic eyes, dogs vocal organs similar to ours, and yet civilization would be far beyond their reach. Man can teach all of them tricks. They themselves can learn something as their life goes on. Chimpanzees may under favourable circumstances, as Köhler has shown, make very simple, human-like inferences; but none of them could initiate and perpetuate the arts and sciences as a heritage of their species.

PROGRESS AND CONSERVATISM

Such then was man's original equipment for getting civilized. He had, obviously, no means of foreseeing the enterprise in which he was engaged. His evolution as a civilized being was no more premeditated than his rise from earlier simian ancestors. There seems to be sufficient evidence that for hundreds of thousands of years changes in his mode of life were so gradual and rare as to pass unperceived. Each generation accepted the conditions in which it was reared without thought of betterment. Our modern hope of "progress"—an indefinite increase of human knowledge and its application to the improvement of man's estate—was practically unknown even to the Greeks and Romans. From the 13th century onward a few writers dwelt upon the promise of the future, but they were outclamoured by those convinced that human woes were attributable to a departure from ancient standards. The Humanists strove to re-establish the wisdom of the classical writers, and the Protestants sought to revive the beliefs and practices of the early Christians. Only three centuries ago did Bacon unroll a programme of aggressive search for the hitherto unknown, which had any very wide influence. In the 18th century the conception of reform and progress found illustrious spokesmen, and their anticipations of coming changes in the economy of human life were destined, as it proved, to be far outrun by the events of the 19th and early 20th centuries.

We can, however, still note on all hands illustrations of man's confidence in routine sanctified by ancient authorities; his suspicion of innovation in wide realms of belief and practice. This dogged obstinacy in clinging to his habits, and his general suspicion of the unfamiliar, are exactly what might have been anticipated when we consider his animal origin. This trait has served to slow down the process of change, but at the same time has greatly increased the security and permanence of each achievement. Here we find a possible explanation of the great rôle that the veil of sacredness has played in man's development. He has cast it over beliefs and practices and so hid them from pert scrutiny and criticism. The number of those who can tolerate somewhat critical thinking here and there, has, nevertheless, greatly increased of late, but they are still few indeed. What we call to-day a conservative or reactionary mood must have been characteristic of mankind from the beginning. It corresponds to animal inclinations.

Among animal proclivities there is, however, from the one-celled organisms upward, a life-saving tendency to make random movements, extensions and contractions, to hasten hither and thither, in the pursuit of food and mates. This restlessness and groping are among man's legacies also. They offset his routine and static habits, and lie behind and back of the inventions and discoveries he has made. There is, too, especially obvious among the higher animals, something auguring what in man becomes curiosity. The danger of attack made preliminary scouting a valuable asset in survival. So men were by nature wont to pry and try and fumble, long before they scientifically analysed and experimented.

There can be no doubt that hundreds of thousands of years were required for man to reach even the lowest degree of culture to be found among the simplest tribes to-day. The discovery of fossil skulls, teeth and bones at different geological levels shows that more or less ape-like men have been on earth for from half a million to a million years. Several species, such as the Java man, the Heidelberg man and the much later Neanderthal race are now extinct. The only vestiges of their handiwork consist in chipped flint tools, becoming better made and more varied

as time went on. There is no way of telling what other arts, beliefs and practices were associated with a particular assortment of flint utensils. Sollas, in his *Ancient Hunters*, has sought to draw ingenious analogies between these prehistoric weapons and the civilizations of the Tasmanians, Australians, Eskimos, etc.

The so-called Cro-Magnon race had finely developed skulls quite as good as those of to-day. To them are ascribed the remarkable paintings and drawings found in caves of southern France and northern Spain. They are believed to be from 25 to 30 thousand years old. Halving this period we come upon traces of ground and polished stone tools, coincident with the relinquishment of hunting as man's exclusive pursuit and a settling down to sow and reap, spin and weave. Halving it again, we get news of the use of copper, the precursor of the metals on which our civilization largely rests. This can but be a rough chronology subject to much revision as time goes on and the earth is more thoroughly searched for evidences of man's past.

To get the matter clearly before one, let us imagine, as the writer has suggested elsewhere, that 500,000 years of developing culture were compressed into 50 years. On this scale mankind would have required 49 years to learn enough to desert here and there his inveterate hunting habits and settle down in villages. Half through the fiftieth year writing was discovered and practised within a very limited area, thus supplying one of the chief means for perpetuating and spreading culture. The achievements of the Greeks would be but three months back, the prevailing of Christianity, two; the printing press would be a fortnight old and man would have been using steam for hardly a week. The peculiar conditions under which we live did not come about until Dec. 31 of the fiftieth year.

There is a school of anthropologists, the diffusionists, who would derive all the higher types of civilization—writing, metallurgy, the construction of imposing stone buildings—from a single region, Egypt. They have collected much evidence to show that through the commerce of the Phoenicians, Egyptian inventions spread eastward into India, China and Japan, then across the Pacific to form the basis of Maya culture in Central America. The merits of the "diffusionist" arguments cannot be considered here. G. Elliot Smith, one of the best known advocates of this theory, dwells on the common lack of inventiveness and the reluctance of mankind to adopt new ideas, his tenacious hold on old ones and "his thick armour of obstinacy." "To obtain recognition of even the most trivial of innovations it is the common experience of almost every pioneer in art, science or invention to have to fight against a solid wall of cultivated prejudice and inherent stupidity."

All anthropologists are well aware of this hostility to change, which we may regard, as shown above, as a natural trait of mankind. They also admit the wide dissemination of inventions through commerce and conquest. Nevertheless many maintain that the same or similar discovery has been made independently in different parts of the earth, as the result of similar needs and conditions. When we have examined the exigencies of successful inventions in the following section we shall see that however commonplace they are now, with the accumulation of the past to build upon and modern facilities to work with, they were beyond measure difficult at the start when mankind still led the life of an animal. When once made and adopted by some tribe it is far easier to think of them as being introduced to other peoples than to assume that their presence represents an independent discovery.

Civilization depends upon the discoveries and inventions man has been able to make, together with the incalculable effects these have had upon his daily conduct, thoughts and feelings. As knowledge and ingenuity increased he departed further and further from his original wild animal life. The manner in which he began to learn is a matter of conjecture, since the manufacture of tools and weapons, the invention of language and artificial ways of producing fire, far antedate any written accounts of advances in man's education. The same may be said of the much more recent spinning, weaving and farming. As we have seen, it required hundreds of thousands of years to reach the degree of civilization represented by these achievements. Their importance, however, cannot be overestimated, since they formed the absolutely essential basis of all later developments. We may feel a certain pride in contemporary inventions, but let us remember that we owe to savage hunters and illiterate neolithic farmers the accumulation of knowledge and skill without which none of our modern experimentation would be possible. Where would we be without fire, speech, clothes and bread!

Since invention, discovery and the increase of knowledge are the stuff of which civilization is made, it is pertinent to our theme to consider how they occur. There is plenty of evidence available in the reports which discoverers now make of the manner in which they reach their conclusions. There is also evidence of how their results are received and acted upon by others. All explorers must be exceptionally curious and at the same time patient gropers. The curiosity observable in most children tends to die away, but survives in one form or another in rare instances through life. These exceptional persons possess a drive alien to their fellows. They may be the handyman of a village or a member of a highly endowed research staff. They avail themselves of what has already been found out; the village mechanical genius does not have to invent a monkey-wrench or bit of insulating tape, nor does the biologist need to know much about the optical principles of his lenses, much less invent or manufacture them. The geologist before he makes any discoveries is familiar with hundreds of treatises on his subject. It would be generally conceded by investigators that their discoveries are seemingly accidental. They do not know what they are going to find, and quite commonly find what they were not looking for, even as Saul, chasing lost asses, came upon a kingdom. All this applies to every kind of increase of knowledge, whether it have to do with the operations of so-called Nature or with novel suggestions in the realms of philosophy or art. All are the result of curiosity, patient examination and thought. At best they are no more than foot-notes and glosses added to existing human knowledge. This is now so varied and voluminous that no single person can compass it except in this detail and that. Should he attempt to do so, all chance of adding to it would be excluded.

But an invention or discovery or the rectification of an ancient error, does not become a part of civilization until it has been accepted by the tribe and been added to its habits of action and thought. Plenty of shocking tales could be recalled of professional and popular opposition to innovations on grounds which now seem grotesque. We owe discoveries to individual men and women, but new information and skill can only be propagated and disseminated in a favourable culture medium. Many instances could be cited of promising knowledge which has so far failed to get a footing in civilization.

The influence of particular discoveries and mechanical devices is by no means confined to their more immediate and obvious applications. It is impossible to foresee what wide-ranging effects they may ultimately exert on human life. Fire will cook a meal, harden an earthen bowl, keep a group of naked savages warm, frighten off prowling animals, soften or melt metals; it may also consume sacrifices to the gods, or form the central interest of a stately temple and be replenished by an order of vestal virgins. It may play its part in the symbolism of the theologian and the poet. The Indians of the North American plains were deeply affected by the introduction of the horse, and African tribes by fire-arms and whisky. The motor car and telephone altered social relations. The perfecting of the steam engine revolutionized the transport of men and their wares; it promoted city life; further, it caused Marx to write a big book which became the gospel of a momentous social upheaval, which threatened the peace of mind of all nations.

The invention of clothes—quite material things, whether of linen, wool, silk or cotton—not only created great industries but enabled men by changing their hide artificially to establish social distinctions akin to biological genera and species. Through clothes entered in prudery and the pious horror of bare bodies which has wrought consternation and disaster among the dark-skinned folk. After the World War women's skirts were gradually shortened. The warmth of houses and vehicles permitted this. One of the conventional distinctions between girls and women

was thus obliterated. The unveiling of women's faces in Mohammedan countries, the breaking down of *purdah* in India—all these material changes imply modifications of woman's life and of the attitude of the sexes to one another. They forecast further important changes in traditional civilization.

In view of these facts, and indefinitely more that each one can easily add for himself, it would seem that what are esteemed the "nobler" aspirations and creations of mankind, whether in art and literature or the pursuit of truth, are all not only dependent upon "material" inventions but so strangely interwoven with them and their effects that it is no easy thing to separate the higher and the lower, except in imagination. What is sometimes called "the higher life of man" arises from his more humble and practical knowledge and skill; accordingly the old distinction between the material and spiritual seems to be greatly attenuated as they are both seen to merge into the newer conception of civilization as a whole. This will become even more apparent when we come to deal with words.

RÔLE OF CHILDHOOD

One of the essential conditions for the perpetuation of civilization is the long period of dependence through which the human child must pass before it gains sufficient bodily strength and intelligence to achieve merely animal self-sufficiency and make its own way. Without the constant and prolonged succour of adults it would speedily perish. This means that the extended period of helpless susceptibility to his surroundings makes it possible vastly to modify a child's original disposition. A mouse is sexually mature in six weeks and fully grown in three months. Calves and colts walk about shortly after birth. The gorilla, on the other hand, has a prolonged childhood, requires ten or twelve years before it is able to breed, and goes on growing, like man, for a few years after. He lacks, however, in spite of his prolonged childhood, the other essential traits which have enabled mankind to initiate, increase and transmit civilization.

We are all born uncivilized and would remain so through life were we not immersed in civilization. There is a long time in which we may, according to the place where we are born, be moulded into a well authenticated Papuan, Chinaman, or Parisian. We cannot choose whether we shall find ourselves talking like a Hottentot, a Russian or a German. And we learn to do in all things as those do among whom we are brought up. We cannot but accept their respective customs, scruples, and ideas, for all these are imposed upon us before we have any choice or discretion. We must perforce follow the ways of our elders, who themselves were once children and gained their civilization before any discrimination or comparison with other than the prevailing habits was possible. This is the inexorable rule, and it accounts for many of the striking characteristics of civilization.

If the assimilation of culture is closely associated with the dependence and adaptability of childhood there need be no great surprise that accumulating evidence seems to indicate that when bodily maturity is once reached, the increase of knowledge and intelligence slackens or even almost ceases in many cases. By 13 or 14 the child has acquired an overwhelming part of the knowledge, impressions, cautions and general estimates of his fellow creatures and the world in which he lives, which he continues to harbour with slight modifications during his lifetime. When as a result of the participation of the United States in the World War it became necessary to test the competence of a great number of young men an unforeseen contribution was made to our insight into civilization. Of the 1,700,000 examined, 45% did not show themselves (to quote an eminent authority, Dr. Henry H. Goddard) "much above the 12-year-old limit." Those tested, it must be remembered, did not include idiots or "morons," but the average run of youths accepted by their fellows as normal. While tests may be as yet inadequate they but confirm the observable fact that the inculcation of culture is associated with bodily growth and especially with the strange changes in the cells of the forebrain and their intercommunications. These developments are tremendous from infancy to maturity in so-called normal cases. Only in exceptional instances does mind-building continue steadily after childhood and adolescence. We have had time before 13 to take over the standardized sentiments of our elders, to learn all that they know, to accept their views of religion, politics, manners, general proprieties and respectabilities. The common run of mankind can, however, be taught tricks as time goes on and acquire special expertness. But a great part of our childish conceptions retain a permanent hold on us. There is usually little encouragement to alter them. We leave most of them unrevised, though we have to make adjustments as the years elapse. Human beings seem on the whole easily subdued to routine and the routine is established, as it would seem, by the time we are grown up. That the *ability* to learn, however, falls off very slowly after adulthood has been recently shown by E. L. Thorndike.

The experts in advertising, the publishers of "tabloid" newspapers and the contrivers of moving picture films seem to conform to the supposition that what appeals to a 12- or 13-year-old child is admirably adapted to the intelligence and tastes of the multitude. This means that the overwhelming majority of men and women assimilate in childhood the common and familiar forms of civilization or culture in the midst of which they find themselves, but hardly outrun them as life goes on. Perhaps one in a hundred may allow his opinions to be altered by assiduous reading, or take pains to cultivate his insight into art and literature and scientific discoveries. But all these and other contributions to one's personal civilization are outside the range of the human animal in general. Indeed the mere upkeep of our present complicated culture must depend upon a very trifling percentage of the population. Were a few thousand carefully selected infants in the various progressive countries of the world to be strangled at birth not only would advances in industry, arts and letters cease but a decline would set in owing to the lack of those to make the essential readjustments in our industries and their financing; to keep up laboratories and books at their present standards. Accordingly the great majority of human beings can barely maintain at best the civilization in which they were reared. Even the innovators considered above, are unable to escape from the toils in which they were so easily enmeshed and which they regard not as entanglements and restraints but as comforts and assurances. It would be faithless and disloyal to regard them otherwise. Only peculiar temperaments under highly favourable conditions question what they have been taught. They can do this only on a most modest scale as a result of continued curiosity and study. A physicist may reach a new theory of the constitution of atoms and yet cling stolidly to the notions of religion he had acquired at ten years of age; he may even engage in subtle philosophical speculation and remain a hot defender of the *mores* of the most commonplace persons 50 years ago.

If these points be well taken the whole contrast between Society and the individual which has been played up in various rather futile ways takes on a new aspect. From the standpoint of civilization each individual owes his entire equipment as a civilized being to others. Biologically even, he is vastly modified by his domestication, in habits, impulses and moods. The so-called "instinct of the herd," which Trotter has made famous, tends to become an unnecessary hypothesis. For every child is made by others in their own image. How gregarious mankind was before the onset of civilization it is impossible to say; but the prolonged infantile weakness implied multiform dependence upon others. Of course there is really no such thing as Society in the sense of some powerful and precious personality for whose welfare the so-called individual is invited to make appropriate sacrifices of personal preferences. What we have to do is to make terms with the notions of "the good" and "the bad" which those profess with whom we are thrown. These rules of conduct and sentiment constitute Society. They have their heavy sanctions if violated or impeached—disgrace, persecution, imprisonment and even death. The methods of eluding Society constitute a highly interesting chapter in the history of civilization. It is not difficult for the shrewd, and seems greatly to enrich life for certain temperaments, whether one be a burglar, a story-teller, or a philosopher. Wholesale deceit has established the reputation and fame of many a hero from Jacob and Ulysses to those in high places to-day. Boldness of thought is less likely as yet to arouse primitive enthusiasm.

WORDS VIEWED AS DEEDS

One of the most stupendous elements in civilization has hitherto been only casually mentioned—words. Without language civilization could hardly even have begun and certainly could never have attained its higher forms. Speech underlies thinking and conscious planning and research. It does more. It creates a world of ideas which interpenetrates and seems to transcend that of the facts of human experience. What pass for facts are indeed so moulded by our notions of them that recent philosophers are less and less confident in their efforts to separate the functioning of ideas from that of facts. Much has been discovered of late which serves to revolutionize the older theories of language and thinking, and to eliminate some of the age-long quandaries in which philosophers have found themselves involved. These new views can be only briefly suggested here.

The Fourth Gospel opens, "In the beginning was the Word; . . . All things were made by it; . . . In it was life; and the life was the light of men." Goethe declared that in the beginning was the deed. The most recent writers who deal with speech would seek to shed new light on civilization by recognizing that words have always been deeds. They have always been regarded as wonder-working acts; they create things which without them could never exist; they are the chief light of man—and his darkness as well.

Making noises is a conspicuous animal trait. Katydids, frogs, whippoorwills, dogs, and many other creatures exhibit a tireless patience in this matter. Man, too, is a great chatterer. His fellow men may be bored by his talk, but they are likely to be scared by his silence. It is portentous and bodes no good. To keep still is an unfriendly act. So, as Malinowski has pointed out, one of the many functions of utterances has been reassurance and the expression of companionability. The cries of animals as related to their needs and behaviour are only just beginning to be carefully studied. Whitman and Craig have discovered a marvellous correlation between the ejaculations of pigeons and their ways of life. Köhler, Yerkes and others are attending to our nearer relatives. But all that needs be noted here is that human language must have emerged from the spontaneous sounds made by pre-man.

Only when men began to make pictures of events and gestures, and painfully developed writing from the pictures, have we the least actual evidence of language. The Egyptian inscriptions illustrate picture writing and its later and most ingenious metamorphosis into sound symbols—an alphabet. This happened five or six thousand years ago. But it is clear from the Egyptian language that its surprising complexity and sophistication imply an antecedent development of incalculable length, to judge from the slowness of man's material inventions.

While the beginnings of language are hidden from us by the lapse of hundreds of thousands of unrecorded years, there are several new ways of coming to a far better understanding of them than hitherto. There are historical and contemporaneous sources of information which have been exploited of late and serve to revolutionize the older views. For example, the so-called primitive languages (until recently, never reduced to writing), afford a sufficient proof that words are fundamentally acts, closely related to man's other conduct. Then, watching the way that babies—the Latins aptly called them *infantes,* or speechless creatures—learn to talk, greatly re-enforces and corroborates the evidence derived from the study of "illiterate" tribes. Lastly, anyone who has learned the trick, can substantiate the same thing if he tests the babble always going on around him.

We have already noted one way in which speech is a mode of action, a friendly gesture, not an expression of thought or conveyance of ideas as philosophers have taught us. "How do you do?" is not a question to be answered under usual circumstances. One concurs in the obvious statement, which conveys no fresh information, "Fine day, sir." These are just tail-waggings, like taking off one's hat, bowing, smiling and hand-shaking. We can, however, do far more with language; we at times can strike with a word more safely and more effectively than with our fist; by words we can cower, and dodge, and elude danger. Those in highest standing in all communities make a living by words, unwritten and written. Whole professions confine their activities to words, —clergymen, teachers (of the older type), lawyers, politicians; brokers deal in alternately saying "buy" or "sell." Doubtless other things lie behind this trafficking, but words are effective acts, or so intimately intertwined with them, that it is impossible to say where one sets in and the other ends. Pure talk and written words seem often to do the business without the intervention of so-called things. The magic operations and achievements of words can be observed everywhere and in all ages. Jacob and Esau struggled bitterly to win a blessing from their blind old father. His words were momentous. They might cause unborn generations to bow down before his son's offspring or doom him and his children to perpetual slavery.

As a clergyman of the 18th century remarked, "Words have a certain bewitchery or fascination which makes them operate with a force beyond what we can naturally give account of." Joy and infinite woe follow in their train; from which our wordless ancestors must have been spared. The main emotional structure of civilization—so poignant and so unique an element in human life—is largely reared on words. They serve to establish new orders of sensitiveness and excitability. Words increase the clarity of our memory to a tremendous degree and at the same time they vivify imagination, which could exist on no considerable scale without them. With these word-created adjuncts we can elaborate our hopes, fears, scruples, self-congratulations, jealousies, remorses and aspirations far beyond anything that seems justified to the onlooker; we can project them backward into the past and forward into the future. Words can rear more glorious palaces and dig deeper, darker dungeons than any made with hands.

TALKING AND THINKING

What has so far been said of the recent views of language helps to explain the newer interpretation of the old terms mind and reason. These seem to be processes, as we have seen, rather than agents. They are ways of doing things rather than things themselves. John Dewey calls his admirable little book on mind, *How We Think.* When older philosophers began to think about thinking, and how by thinking we reached truth, they commonly found themselves writing very long books, very hard to read; and they called their great theme epistemology or the theory of cognition. The effective thinking which has built up civilization has not, however, relied upon their treatises; nor has it been influenced by them. Two or three considerations only can be touched upon here which impress recent students in investigating thinking.

Thinking and words go together. For thinking, to be clear, has to rely upon names and their various associations with one another. For instance, grocer's bill, cheque-book, fountain-pen, envelope, stamp, letter-box are names put together in a particular sequence. Of late there has been a good deal of discussion as to whether thinking was not always talking quite noiselessly to ourselves. A child will first utter sounds at random, then begin to find that the sounds he makes bring things; then he gets to naming with vast enthusiasm; then he prattles too freely and inopportunely to please his elders; then he may merely move his lips—as many childish people continue to do—and finally hold his tongue. It can be shown, however, by appropriate tests that this suppressed talking is accompanied by muscular adjustments of the vocal organs which indicate a silent execution of the words and sentences. We can say openly "That's too bad," or mutter it, or adjust our organs so as to say it if we wished. This suppressed talking seems to be thinking. That all thinking is merely talking to ourselves many will doubt or deny. While some minor reservations are justifiable there is an overwhelming mass of evidence, derived for instance from the study of deaf mutes, that fortifies the contention stated above—no words, no thinking.

But thinking can easily be seen to be of several varieties. There is the meandering succession of recollections, vague apprehensions, hopes, preferences, disappointments and animosities which has come to be called *reverie.* It underlies other and more exacting forms of thinking. It is found on inspection to consist of recollections, anticipations, excuses for past or contemplated con-

duct, reflections on the unfairness of our fellow creatures and of the world in general; or assurances that all is well and must in the nature of things remain so. Ordinary daily planning is an essential form of thought—making homely decisions and adjustments. Underneath, we can perceive the reverie flowing as a sort of undercurrent—for thinking is very complicated.

We occasionally turn our thinking to trying to find out something that we do not yet know. This may be the result of mere personal suspicions and vulgar curiosity, or of an honest desire to improve a defective social situation, or learn more of light waves, Chinese paintings, psychoneuroses or investments. In dealing with the workings of the physical universe a special kind of thinking, the mathematical, has produced results that tend to safeguard the investigator from the usual prejudices which beset us in all thinking. It is a peculiar, highly refined language, or way of talking about things, by employing the vocabulary of sines and cosines, logarithms, constants, variables, roots, powers, etc. It has proved to be a wonderfully fruitful way of talking about light, for instance, and the nature of "matter" and "force" and in dealing with engineering problems. Few are addicted to this type or any other variety of scientific thinking. Most practical inventions seem to proceed from our power to experiment by thinking; to fumble and stumble mentally, and sometimes succeed. This mental trying-out is a kind of trial and error. It cannot proceed long without various external acts to check up the guesses and inferences produced by meditation.

One of the most novel and promising methods of learning more about all kinds of thinking is abnormal psychology. Illusional and obsessive thinking which fill the mad-houses appear to be only the exaggerations of the thinking of those at large. The psychiatrists hold out hopes of discovering through their special knowledge, and a study of infants and children, ways of eliminating or reducing some of the vices of civilization as it has hitherto developed. To them civilization is in many of its manifestations a species of mild madness; these can only be eliminated by a great change in the way children are brought up, so as to obviate the maladjustments and distress incident to a rapidly altering cultural environment.

Men and women think not only when they are awake but when they are asleep. Their sleeping thoughts and visions and experiences we have learned to set off sharply—far too sharply as it would appear—from waking thought. Primitive man did not do this. He did not deem his dreams mere illusions, comical or distressing, to be banished when he opened his eyes. They were not negligible to him but quite as real and instructive for conduct as what he saw in the day-time. Indeed they had a weight and authority superior to the pronouncements of daily experience; and they served vastly to widen it. What civilization would have been without the manifold influences of dreams it is quite impossible to guess. Had man been dreamless would he have had his religions, his symbolism and his allegories, his poetry and much of his art? This much at least is assured that the beliefs and practices of primitive peoples are in many cases directly attributable to their dreams. Later beliefs and practices of more elaborately civilized peoples can usually be traced back to primitive ideas, which seem to be the soil from which they sprang. So we have to conclude that dreams are one of the most remarkable factors that have entered into the fabrication of civilization as we know it to-day.

When asleep we find ourselves visiting distant places; for instance when walking the streets of Paris we suddenly wake in New York. How could early men escape the conviction that they had a second self which could wander forth from the body, leaving it behind in the hut, while the "spirit" led for a time an emancipated and adventurous existence freed from the slow and lumpish flesh? Then in dreams the dead appear to us in full life and activity. They may admonish or fortify us; rebuke our departure from the old ways, or fill us with assurance of success. The North American Indians shared the confidence of the ancient Hebrews and Romans in dreams. In India and China the veneration of ancestors forms a highly practical obstacle to the introduction of Western institutions. So have we here, without the possibility of much question as to the main issues, a fair explanation of the original belief in the spirit or soul and its survival of death. We have much more. We have the dawn of the gods and the demi-gods, and the whole foundation of beliefs about supernatural beings and their converse with men; their anger and the possibility of their propitiation by sacrifice.

LOOKING FORWARD

In the preceding sections of this article certain important considerations are enumerated which escaped until recently the attention of students of mankind. They are clear enough when once pointed out. But it has always been a tragic trait of civilization that the obvious has been difficult to perceive, for it is too familiar to catch our attention. It requires a peculiar penetration to discover what in all discussions we are unconsciously taking for granted. And what we are most prone to take for granted are unrevised childish impressions.

There is much complaint of the childishness of mankind, which has become more conspicuous with the democratic assumption that everyone should have his say. Langdon-Davies' *New Age of Faith*, and E. C. Ayres' *Science the False Messiah*, to cite two examples, dwell with some petulance and bitterness on the easy gullibility and obstinate ignorance of humanity. They assume standards of intelligence which obviously do not prevail, as one reads popular newspapers, sermons and political speeches. They are disappointed, but have no reason to be surprised. Why should an ex-animal not have made grotesque mistakes as he floundered about with words and besetting mysteries and hardened orthodoxies? Then, as we have seen, civilization is mainly acquired in childhood and perforce ever haunted with infantile longings and misapprehensions. When there is an issue between his dreams and visions and his waking experiences why should man not prefer the former? As a matter of fact those reputed as great and deep thinkers have dealt mainly, until very recently, with imaginary beings, with events that never happened; with empty concepts, allegories and symbols and false analogies. John Dewey has in his *Reconstruction in Philosophy* deduced philosophy and ethics from savage antecedents and shown how these have interpenetrated later speculations. The hardly to be overcome prejudice which attributes to mind and body separate existence and regards them of diverse substance is the easily explained and inevitable mistake of a savage. The will, the unconscious, the moral sense, regarded as agents, belong to the category of primitive animistic conceptions. Even causation as it used to be conceived is but an expression of the naïve urge to blame or praise some particular person or thing for this or that event. We are now learning to think in terms of situations. For example when Edward Carpenter wrote many years ago on *Civilization, its Cause and Cure*, he yielded to a venerable usage. It has become apparent enough that civilization has had no one cause but is the result of a situation of cosmic complexity. There can be no one cure for its recognized defects. A recent Italian writer, Pareto, has filled two large volumes with instances of the misapprehensions upon which current sociological treatises are based.

As humanity, or at least their leaders, become more fully aware of the nature and origin of civilization and the manner in which it has hitherto developed they will discover firmer foundations on which to build, more efficient ways of eradicating the inevitable and congenial errors of the race, and of stimulating patient and fruitful reconstruction and reform. So far mankind has stumbled along, enslaved by its past rather than liberated by it for further advances. The reasons for this are beginning to become more apparent than ever before and might as time goes on be made the basis of a type of education, especially in man's early years, which would greatly forward and direct the progress of civilization rather than retard its development. (J. H. Rob.)

CIVIL LAW, a phrase which, with its Latin equivalent, *ius civile*, has been used in a great variety of meanings. *Ius civile* was sometimes used to distinguish that portion of the Roman law which was the proper or ancient law of the city or state of Rome from the *ius gentium*, or the law common to all the nations comprising the Roman world, which was incorporated with the former

through the agency of the praetorian edicts. This historical distinction remained as a principle of division in the body of the Roman law. The municipal or private law of a state is sometimes described as civil law in distinction from public or international law. Again, the municipal law of a state may be divided into civil law and criminal law. The phrase, however, is applied par excellence to the system of law created by the genius of the Roman people, and handed down by them to the nations of the modern world (*see* ROMAN LAW). The civil law in this sense would be distinguished from the local or national law of modern states. It is further to be distinguished from that adaptation of its principles to ecclesiastical purposes which is known as the canon law (*q.v.*). In countries which have codified their law the civil code contains the legislation which governs the civil relation of the citizens *inter se*, but excluding subjects dealt with in special codes, such as commerce, procedure and crime. It therefore includes citizenship, marriage, divorce, contract, sale, partition, exchange, mortgage, usufruct, servitudes, succession, wrongs and so on. (*See* CODE.)

CIVIL LIBERTIES. The word "liberty" describes social situations characterized by an absence of restraint. Civil liberties are personal and social liberties guaranteed by law. Granted freely by an outside sovereign and revocable at will, a liberty is a "privilege"; but if claimed and enforced by and for the people concerned, liberties become specific "rights." Every right has its negative and its positive aspects: liberties are the negative aspects of rights, freedoms the positive. Freedom is self-direction: it is not an automatic result of liberty.

On the negative side are found personal security of life and limb from bodily restraint and violence (*i.e.*, from slavery, lynching, raiding and other irresponsible uses of force); safeguards of private property; the sanctity of the home; the defense of reputation; protection from unfair taxation, from class legislation and from ex post facto laws, bills of attainder, and double jeopardy.

To these negative aspects correspond certain positive aspects of rights, more properly called freedoms. Such are the right of self-defense; freedom of movement and residence; the right to privacy, and freedom of choice in marriage and childbearing; the positive rights of ownership; freedom of contract; freedom of competition; equal access to legal procedures; freedom of conscience and worship; freedom of communication (speech, publication, arts). Freedom of assembly involves freedom of movement and of speech.

If a right is a claim upon the conduct of other persons, that corresponding conduct is a duty; if a right is a claim upon the state, there are those who insist that it is the duty of the state to implement the right with such facilities as permit its exercise. When social standards are asserted as rights, such as the "right to be well born," "rights to safety, play, education," they can properly be called such only as the state validates them by providing the wherewithal to convert liberty into opportunity. Freedom of press is useless without paper, type or news space; freedom of speech is useless without halls, space or airtime.

Civil rights protect certain universal human needs and interests from other equally human needs and interests and (when rights conflict) each right is defended from the other's claims. The adjustment of conflicting claims is the function of legal justice in the courts, or (ultimately) of social justice through the legislature or direct action. Rights are claims which the courts will enforce: legislation becomes law in the fullest sense when courts uphold it. It is, therefore, in the processes of the courts that civil liberties become rights. The rights to a fair trial, and the several special safeguards thereof, become indispensable means for the preservation of liberties, freedoms, democratic responsibilities and orderly social change. Due process of law is guaranteed through the rights of proper arrest, counsel, habeas corpus, equality before the law, indictment, prompt public trial by jury, challenging the prejudices of judge or jurymen, confrontation of witnesses, reasonable bail, reasonable penalties.

The right to due process of law (which is thus supposed to protect one's various liberties and freedoms) may actually begin, paradoxically, with a right to be arrested; *i.e.*, to be legally held for due process instead of being coerced, kidnapped, sequestered or deported irresponsibly. The right of habeas corpus (*q.v.*) is another basic and essential aspect of this safeguarding of due process against lawless police or other star chamber or gestapo tactics by officers of so-called law and order, secret or private police, or irresponsible vigilantes. The period of sedition trials, during which (1794–1801) the writ of habeas corpus was suspended, was also a period of low ebb in other English liberties, in reaction against excesses in the French Revolution.

Civil liberty includes those liberties which involve civic relationships, and is thus distinguished from moral liberty or freedom of will, from political liberties, from economic liberties and from academic freedom. Each of these fields overlaps civil liberties to the extent that law supports liberty of conscience, self-government, industrial or academic liberty.

Political liberty comprises the right of franchise; the rights to petition and to hold office; safeguards of the people's representatives and judges from intimidation and undue influence; the right of equality before the law, regardless of such circumstances as race or colour, with safeguards of due process before, during and after trial, without discrimination; and the right to bear arms.

Economic rights were developed first for enterprisers as freedoms of ownership, trade, competition, contract. Free competition and contract extended to labour but proved as much a danger as an opportunity, until supported by the civil rights of collective bargaining. The rights to organize, to bargain through representatives of their own choosing and to strike provide the chief guarantees and opportunity for other economic freedoms. Major issues, as to whose freedom shall limit whose, lie frequently in the field of distribution of wealth and of economic power over wealth and persons. Where this is the situation, those who are currently in control of industrial property and financial credit (hiring power) naturally resist or attack movements from the left, the have-nots, all those who are claiming new rights in the name of labour, share-croppers, tenants, dependent minority races, etc. Extremists in support of property rights and the *status quo* may, by contrast, advocate or permit anti-democratic (*i.e.*, irresponsible) measures with relative impunity. Much labour legislation now accepted as constitutional exercise of the police power of the state in the general welfare can be considered, from this angle, as establishing economic rights of labour—positive civil rights to a living wage and living leisure, health and security, and the corresponding negative rights of liberty from want, exploitation, domination and fear, whether through forced labour, peonage or mere bargaining power.

Academic freedom is not a civil liberty but a professional claim to certain complementary responsibilities and immunities in the interests of the integrity of scientific and scholarly research and of the teaching and learning process, such integrity being considered indispensable to the valid services of educators, scholars and scientists to the community at large. The area of academic freedom overlaps that of civil liberties in that teachers are often penalized as teachers for words or acts outside the classroom which constitute legitimate exercises of their rights as citizens.

The traditions of stubborn individualism and specific civil rights imported to America during the colonial period were strengthened by frontier conditions and by struggles against British Tory governors, and were later kindled into idealism by the more abstract and emotional libertarianism of French thinkers. The doctrine of rights reserved to the people implied that "natural" liberty was like an endowment fund, from which (by social compact) capital could only be alienated in exchange for a demonstrated *quid pro quo* of common welfare or legal rights. Reserved "natural rights" become bills of rights when they reappear in political compacts, charters or constitutions. Actual legal liberty becomes the defense of "reserved rights" from invasion. "Natural rights" being (according to the metaphysical theory) part of a person, the right of self-defense may be claimed for them, if

legal protection is inadequate. Social conflicts still arise in which the logical confusion between the specific, concrete civil rights of Anglo-Saxon history and the rationalistic and metaphysical bases of "civil liberty" becomes apparent.

History of Civil Liberties.—Every culture has permitted its own liberties. The civil liberties as we know them are a cultural-legal complex deriving from the Anglo-Saxon cultures, especially from the common law, from certain historic enactments and from certain philosophic doctrines. These, in turn, derived from centuries of interaction of conquerors and conquered; of king, barons and commons; of church and state; and from earlier ideas of rights, justice, law, nature, reason, reserved powers, sovereignty, allegiance, contract and freedom, traceable in the intellectual history of Europe and of Asia.

Even preceding the Christian doctrines of free and equal souls, the stark moral autonomy claimed for the individual by the Stoic philosophers, and their faith in nature and reason are historical sources for the later doctrines of natural rights superior to law, and of duties taking precedence of the demands of family and state. Christianity developed a discipline of freedom of conscience capable of martyrdom. Mediaeval feudalism seems to the layman anything but free, yet even in feudalism the individual nature of the compacts of allegiance is considered a forerunner of the right of free contract, as well as of the political theory of the social compact limiting liberty. In mediaeval cities persons split off from the feudal hierarchy acquired a new independence as burghers and as craftsmen. The charters of the guilds often safeguarded their members' liberties, though guild regulations represent anything but economic liberty in any modern sense. Freedom of parliamentary debate was won in England under James I—an early victory for free speech.

For certain aspects of civil liberty of religion the period of the Reformation is responsible; *e.g.*, the treaty of Augsburg (1555) and the edict of Nantes (1598). In the Protestant Reformation the independence of conscience, duty and will before God were reaffirmed. This root of liberty is to be seen flourishing in the English Puritan revolution (*e.g.*, Agreement of the People of England, 1647). Both in French and in German thought, however, as in Thomas Hobbes, there were also elements of absolute collectivism and doctrines of the folk-will or state-will which conflicted with libertarianism. Full religious liberty came in America before it was approximated in England, which still taxes for the support of a state church.

The charters of Anglo-Saxon liberties are: Magna Carta (1215); the Statutes of Westminster (1275); the Petition of Right (1628); Bushell's Case (trial by jury, 1670); the Habeas Corpus act (1679); the Bill of Rights (1689); the Toleration act (1689); the Acts of Settlement (1700–1701); the Libel act (1792). Parliament refused in 1695 to renew the Licensing act, thus abolishing censorship. One might well add such nonlegal classics as John Milton's *Areopagitica* (1644), Thomas Paine's *Common Sense* (1776) and *Rights of Man* (1791), and John Stuart Mill's *On Liberty* (1859). The content of these documents has penetrated and been incorporated into American constitutions and legal decisions.

American liberties are still basically English: even American colonial "ancestors" considered themselves Englishmen. The origins of England's liberties, however, include important contributions from the experience and fearlessness of her American colonial "radicals." The well-known intolerance of many early colonial governments may seem less culpable if it be recalled that they could hardly be said to violate liberties not yet legally established in England itself. Indeed, American libertarianism had its share in effecting English constitutional liberties and stimulating French libertarian thought. In New England, and later in old England, congregational democracy was extended into political democracy. The earliest American colonists brought with them the same ferment of ideas which was working during the English revolutions of 1648 and 1688, such as those of the state of nature and the social compact. The Mayflower covenant and the doctrine of the sovereign autonomy of the soul may be considered, therefore, as religious prototypes of Jean Jacques Rousseau's natural rights and social contract. Once established in early New England the social-compact idea took precedence of the libertarian: heretics were treated as violators of the collective covenant. Later, natural rights were invoked to justify religious liberty as a corollary, and revolutionary French political theories were influential during and after the American Revolution.

In America, early milestones of liberty include Maryland's Toleration act (1649), the charter of Rhode Island (1663) and the Zenger case (New York, 1734). Classics of the later colonial period are James Otis' *The Rights of the British Colonies Asserted and Proved* (1764) and Samuel Adams' *The Declaration of the Rights of Men* (1772). The First Continental Congress issued a Declaration of Rights and Liberties (1774) and the less-known Address to the Inhabitants of Quebec.

Once split off from England, the American states promptly included bills of rights in the new constitutions, protecting the people's liberties against their own governments and (less effectively) against the tyranny of majorities. Virginia's Declaration of Rights preceded the Declaration of Independence by three weeks, and served as model for 11 states before the federal Bill of Rights amendments were incorporated in the constitution. Among early state bills of rights those of Maryland (1776), New York (1777) and Massachusetts (1780) are notable, as is Virginia's statute of religious freedom (1786).

Major documentary milestones of American civil liberty since the Revolution have included the Ordinance for the Government of the Northwest Territory (1787); the first ten amendments to the federal constitution (the Bill of Rights, 1791); Amendments XIII, XIV, XV (the Civil War amendments, 1865–70); and certain judicial opinions of Justices Oliver Wendell Holmes, Louis Dembitz Brandeis, Learned Hand and Benjamin Nathan Cardozo.

Developments in the United States.—The tensions and enforced regimentation of wartime subject civil liberties to serious danger. During World War I both England (Defense of the Realm act) and the United States (Espionage acts) sharply limited freedom of discussion and of political criticism, and court interpretations and sentences under the Espionage acts were even harsher. Advocacy of change was called obstruction. Persons expressing opinions alleged to be adverse to the current policy of the then government, even under conditions not dangerous to public safety, were punished by heavy prison sentences, often for statements later corroborated by high authorities or by actual events. Public opinion was hysterically suspicious and intolerant. State and local authorities were often more drastic than federal and military authorities. Speech and press were muzzled if the prosecutor could impute "evil tendency" or "constructive intent," even by indirection. Even silent non-co-operators and nonsubscribers were persecuted. Many offenders convicted for honest devotion to political and economic principles were treated worse than violent criminals. Conscientious objectors and other pacifists were brutally treated until a more equitable procedure was set up by the war department.

During the post-World War I period, with general disillusionment in regard to the motivation and outcome of the war, attitudes toward war offenses relaxed and most of the extreme sentences were commuted or the prisoners pardoned. On the other hand, the anti-German hatred was shifted into anti-bolshevik and anti-labour-union channels, and epidemics of repressive laws, "red-raids," prosecutions and deportations ensued. Mere membership in organizations alleged to hold certain opinions was heavily penalized, thus creating guilt by association. Many liberals felt that existing laws against overt acts had been adequate; that the sabotage, sedition, criminal syndicalism and anarchy statutes were enacted chiefly to facilitate the crusades against so-called radical organizations. The later vicious tactics of some such groups have been attributed to the hatreds inspired by their experiences in this period.

The civil liberties record in World War II was a great improvement over that in World War I. In part this may be attributed to a somewhat more sophisticated public attitude toward wartime propaganda, but there was also a determined effort on the part of responsible government officials to avoid the excesses of World War I. The wartime attorney general, Francis Biddle, exercised a restraining influence, and so did the supreme court. The most flagrant abuse of freedom was the enforced evacuation of about 112,000 persons of Japanese ancestry (70,000 of whom were full-fledged U.S. citizens) from the west coast by the army. This drastic step was taken on the ground that there were likely to be persons guilty of espionage or sabotage within this group, and that the emergency did not permit screening on an individual basis. The supreme court, by decisions in 1944 and 1946, accepted this plea of military necessity, but it later became widely believed that the mass evacuation, with its attendant hardships and loss of property, was an unjustifiable action falling, as Justice Frank Murphy charged, "into the ugly abyss of racism."

The wartime alliance of the United States with the U.S.S.R. led to some lessening of American apprehension concerning the communist threat. But with the close of the war the Russian leaders quickly demonstrated their intention of pursuing an aggressive and imperialistic policy, and of using the international communist movement to bring under Russian domination the government of every country not strong enough to resist its subversive influence. In the resulting "cold war," feeling against communists or alleged "fellow travellers" in the United States grew very strong.

Legislative expressions of anti-communism included the Smith act of 1940, punishing conspiracy to overthrow the government by force or violence; the Labor Management Relations (Taft-Hartley) act of

1947, requiring the signing of non-communist affidavits by labour union officials; the Internal Security act of 1950, setting up a subversive activities control board with which "communist-action" organizations were required to register; and a number of statutes adopted by congress in 1954, of which the Communist Control act, undertaking to "outlaw" the Communist party, was the best-known.

Activities of certain congressional committees, particularly the house committee on un-American activities and the senate committee headed by Sen. Joseph R. McCarthy of Wisconsin, raised controversies as to alleged invasions of civil liberties through secret hearings, refusal to permit the presence of counsel, acceptance and publication of character-damaging hearsay evidence, refusal to permit witnesses to make statements, harassing questioning, etc. These and similar practices led to demands, in congress and out, for a code of conduct to govern legislative inquiries. Individuals who sought to resist committee questioning into their political views or past associations were generally unsuccessful. They could decline to testify on the ground that their answers might tend to incriminate themselves (5th amendment), but such a plea was generally regarded as a confession of guilt.

There were of course other kinds of civil liberties problems following World War II. The treatment of certain minority groups continued to fall short of the constitutional standard of equal protection of the laws, but progress was evident, most notably in the supreme court's 1954 decision holding racial segregation in the public schools unconstitutional. Scattered efforts toward censorship of books were largely frustrated, and censorship of plays and movies was increasingly under attack. Standards of criminal prosecution in state courts were often rather low, but vigorous supreme court resistance to the use of coerced confessions, unrepresentative juries, unreasonable searches and seizures and other violations of due process were having salutary effects.

After World War I a number of organizations specializing in defense of one or another area of freedom were formed. The American Civil Liberties Union, however, remained the only nonpartisan, general and nation-wide agency with a consistent record of defending groups and persons threatened or injured in respect to civil rights, without sponsoring their ideas or programs.

Freedom of Speech and Press.—The 1st amendment of the U.S. constitution provides: "Congress shall make no law . . . abridging the freedom of speech, or of the press." While the amendment applies only to congress, the supreme court ruled in 1925 that the same prohibition is applicable to the states by reason of the 14th amendment's guarantee against deprivation of "liberty" without due process of law (*Gitlow* v. *New York*, 268 U.S. 652). Governmental infringement of free speech or press can occur in two general ways, either by previous restraint of publication, more commonly called censorship, or by punishment after the event for words spoken or published.

Censorship has generally been regarded as the more serious type of restraint. In fact, Sir William Blackstone argued that the liberty of the press consisted only "in laying no previous restraints upon publications." However, it is now clear that freedom from censorship is not sufficient protection for, unless there are effective limits on prosecution, punishment for what one has said or printed can be just as effective in discouraging free discussion.

American feeling against censorship has been so strong that, except for military information in wartime, attempts at prior restraint on speech or press have been most uncommon. In 1931 the supreme court had an opportunity to state the basic case against censorship in declaring unconstitutional a Minnesota statute under which a newspaper had been enjoined from publishing as a public nuisance (*Near* v. *Minnesota*, 283 U.S. 697). The court has also warned that the post office department's power to deny second-class mailing privileges to periodicals cannot be employed for censorship purposes (*Hannegan* v. *Esquire*, 327 U.S. 146, 1946), nor can a state seek to punish newspapers through discriminatory tax legislation (*Grosjean* v. *American Press Co.*, 297 U.S. 233, 1936). Handbills dealing with public issues share fully in the constitutional protection accorded the press, and their distribution cannot be subjected to police interference or licence requirements (*Lovell* v. *Griffin*, 303 U.S. 444, 1938; *Schneider* v. *Irvington*, 308 U.S. 147, 1939).

The spoken word presents somewhat different problems from those of the press, chiefly in that oratorical appeals, particularly in a crowd situation, are more likely to result in action. If the action urged by speech is illegal or sufficiently dangerous to the public welfare, the speech cannot claim constitutional protection. There is no right falsely to cry "Fire" in a crowded theatre, said Justice Holmes.

Speech enjoys a wide protection from prior restraint, however. Licences cannot be required for speaking on the streets or in public parks (*Kunz* v. *New York*, 340 U.S. 290, 1951), unless the licensing system is one which gives public officials no discretion in the granting of permits (*Poulos* v. *New Hampshire*, 345 U.S. 395, 1953). As to amplified speech the situation is less clear. In 1948 the supreme court held licensing of sound trucks invalid (*Saia* v. *New York*, 334 U.S. 558), but one year later it approved regulation aimed at protecting the public from "loud and raucous" devices (*Kovacs* v. *Cooper*, 336 U.S. 77). Then in 1952 the court refused to protect the "captive audience" on District of Columbia streetcars from having to listen to commercial advertising broadcasts (*Public Utilities Commission* v. *Pollak*, 343 U.S. 451).

Peaceful picketing in labour disputes was given the status of speech and the protection of the 1st amendment by the supreme court in 1940 (*Thornhill* v. *Alabama*, 310 U.S. 88). However, subsequent decisions retracted some of this protection, on the ground that picketing, in addition to being speech, is also a means of economic coercion which is not constitutionally privileged. Injunctions have been approved by the court where the picketing, though peaceful and truthful, was seeking a purpose unlawful under state law (*Giboney* v. *Empire Storage & Ice Co.*, 336 U.S. 490, 1949), or even where the purpose was merely one which a state judge believed contrary to public policy (*International Brotherhood of Teamsters* v. *Hanke*, 339 U.S. 470, 1950).

The theatre has historically been subjected to licensing requirements, normally aimed at enforcing moral standards. Censorship has likewise been widely imposed on motion pictures, but in 1952 the supreme court denied New York the right to prohibit a film on the ground that it was "sacrilegious," which was held to be too vague a standard (*Burstyn* v. *Wilson*, 343 U.S. 495). Radio and television stations are subject to government control to the extent that they require licences in order to broadcast, which may be revoked or not renewed if a station's operation is found by the Federal Communications commission not to be in the public interest. However, the FCC has used this power with extreme caution. Moreover, the Federal Communications act forbids the FCC to exercise any power of censorship over programs, and obliges stations to afford all legally qualified candidates for public office equal opportunity to use their facilities.

It is not contrary to principles of free speech that individuals should be held responsible for abusing this freedom. Individual injuries resulting from speech which is malicious or false can be punished under the libel and slander laws. However, in the law of libel it was gradually established that a jury, not the judge, decides what is libellous; and, in certain cases, demonstration of good (*i.e.*, nonmalicious) motives in announcing a truth or fact is considered a valid defense against libel suit (*see* LIBEL AND SLANDER).

Difficult problems are encountered when speech is sought to be punished because of its alleged danger to public order or to the national security. An individual can be held responsible for speech which causes breach of the peace. There is no freedom of speech for "fighting words" likely to provoke their target to physical assault (*Chaplinsky* v. *New Hampshire*, 315 U.S. 568, 1942). The supreme court has ruled that police can arrest a sidewalk speaker when in their judgment his words are tending to provoke disorder (*Feiner* v. *New York*, 340 U.S. 315, 1951). The court has also upheld the conviction of a zealot who circulated anti-Negro leaflets and petitions on Chicago streets; he was prosecuted under a group libel law which punished the exposure of "citizens of any race, color, creed, or religion to contempt, derision, or obloquy" (*Beauharnais* v. *Illinois*, 343 U.S. 250, 1952). These two latter decisions, however, were attacked by a minority of the court as dangerous limitations on freedom.

Clearly some standard of judgment is needed to aid in determining when speech may be constitutionally limited because of its threat to public safety. The best known test is the "clear and present danger" rule first stated by Justice Holmes in a case arising out of the Espionage and Sedition acts as applied during World War I. In *Schenck* v. *United States* (249 U.S. 47, 1919) he said:

"The question in every case is whether the words are used in such circumstances and are of such a nature as to create a clear and present danger that they will bring about the substantive evils that Congress has a right to prevent. It is a question of proximity and degree."

In the Schenck case a pamphlet had sought to encourage resistance to the draft, and Holmes concluded that such speech deserved no constitutional protection.

"When a nation is at war many things that might be said in time of peace are such a hindrance to its effort that their utterance will not be endured so long as men fight and that no Court could regard them as protected by any constitutional right."

But in later cases when he sought to use the test to protect speech which he believed was constitutionally privileged, the court majority voted against him. It was not until the 1930s and 1940s that the clear and present danger test was actually utilized by the court to keep men out of jail on speech charges. During this period several significant decisions safeguarded the free speech rights of communists or radicals (*DeJonge* v. *Oregon*, 299 U.S. 353, 1937; *Herndon* v. *Lowry*, 301 U.S. 242, 1937; *Bridges* v. *California*, 314 U.S. 252, 1941). But in 1951 the supreme court found the conviction of the top leaders of the Communist party in the United States to be justified under the clear and present danger test (*Dennis* v. *United States*, 341 U.S. 494). Admittedly there was little likelihood of successful communist overthrow of the government, but Chief Justice Fred M. Vinson said that the clear and present danger test obviously "cannot mean that before the Government may act, it must wait until the *putsch* is about to be executed, the plans have been laid and the signal is awaited. . . . We must therefore reject the contention that success or probability of success is the criterion." Justices Hugo L. Black and William O. Douglas, dissenting, contended that this position repudiated the clear and present danger test.

Freedom of Assembly and Organization.—There are no specific provisions in the U.S. constitution protecting rights to assemble and to organize, but these are basic to a free society. It is characteristic of totalitarian systems that the state takes a monopoly of association and terminates the free formation of groups. Even in a free society, however, freedom of assembly and organization is limited, as for example by the law of conspiracy. Organizing becomes conspiracy if the ac-

tivities organized collectively are themselves illegal. Acts protected if performed alone may also be declared lawless if done together, by agreement, especially in a "dangerous" situation. The Smith act punishes conspiracy to organize a party to advocate the overthrow of the government by force and violence. All labour unions, not to mention strikes, were at one time regarded as conspiracies, but that period is long past. The National Labor Relations (Wagner) act of 1935, as amended in 1947, granted full legal status to collective bargaining and labour organizations.

Freedom of organization of course includes the right to form political parties. However, political parties in the United States actually operate within a network of legal limitations covering such matters as when and how primary elections shall be held, how a party gets its nominees on the election ballot, how much money may be spent in elections, and the like. The network of statutes adopted against the Communist party after World War II rested on the belief that it was not a bona fide political party, but rather a conspiratorial revolutionary organization.

An important element in the concept of freedom to belong to organizations is protection of the individual from guilt by association. Some interesting questions in this field were raised by the loyalty-security investigations of federal government employees during the "cold war" period. The U.S. attorney general, under authorization by the president, prepared a list of subversive organizations. The list was originally intended as a guide to federal boards in passing on the loyalty of employees, but it was widely publicized and membership in a listed organization had grave consequences for many individuals. Organizations so listed found it difficult to continue in operation. Because of these serious results, the supreme court ruled that the attorney general must give notice and hearing to organizations before placing them on the list (*Joint Anti-Fascist Refugee committee* v. *McGrath*, 341 U.S. 123, 1951).

The guilt by association standard was also invoked in connection with loyalty oaths required by some states and cities for public employees, candidates for public office, and even in some instances tenants in public housing projects. The supreme court, which passed on several statutes involving oaths of nonmembership in subversive organizations, insisted that individuals must have had knowledge of the unlawful character of an organization before they could be penalized for having joined it. A state law which failed to distinguish between innocent and knowing association was declared unconstitutional (*Wieman* v. *Updegraff*, 344 U.S. 183, 1952). On the other hand, the court upheld a New York statute which made membership of schoolteachers in certain listed organizations prima facie grounds for their disqualification, saying, "From time immemorial, one's reputation has been determined in part by the company he keeps" (*Adler* v. *Board of Education*, 342 U.S. 485, 1952).

Freedom of assembly is limited by freedom of movement in the use of the streets and by the police power in respect to public safety (*Cox* v. *New Hampshire*, 312 U.S. 569, 1941). The right of assembly is further limited by the law of riot; in constitutional law it usually appears as the right *peaceably* to assemble. In 1949, however, the supreme court went so far as to protect from a disorderly conduct charge a speaker whose inflammatory remarks in a private meeting hall provoked a riotous situation (*Terminiello* v. *Chicago*, 337 U.S. 1).

Freedom of Religion.—"Free exercise" of religion is guaranteed by the 1st amendment of the U.S. constitution, and religious practices and preaching are not legally interfered with unless they are aggressive as "nuisances," offend public morality (as by the original Mormon practice of polygamy), violate secular laws or are dangerous to the government. Draft laws can be enforced against conscientious objectors, but in practice such individuals are assigned to other types of national service. The supreme court originally approved denial of citizenship to conscientious objectors who in applying for naturalization declined to take oath to defend the United States by force of arms, but this position was reversed in 1946 (*Girouard* v. *United States*, 328 U.S. 61). The unorthodox beliefs and practices of the Jehovah's Witnesses sect resulted in many encounters with the law, and they have often been supported by the supreme court, as when the court upheld the refusal of their children to salute the flag in public school exercises (*West Virginia State Board of Education* v. *Barnette*, 319 U.S. 624, 1943).

The provision of the 1st amendment forbidding congress to make any law "respecting an establishment of religion" renders state support for churches unlawful in the United States. However, it does not mean that a complete wall of separation must be erected between church and state. Even financial assistance in the form of tax exemption has not been questioned, so long as it is available to all religious groups. The principal establishment issues have concerned state aid to religious schools. In 1930 the supreme court upheld a Louisiana law providing free text books to pupils in both public and private schools, on the ground that the aid was to the child and not to the school (*Cochran* v. *Louisiana Board of Education*, 281 U.S. 370). In 1947 it likewise upheld a New Jersey provision under which parents were reimbursed from public funds for the cost of transporting their children to parochial schools (*Everson* v. *Board of Education*, 330 U.S. 1). In 1948 the court did rule unconstitutional a Champaign, Ill., arrangement whereby public school pupils were released from classes for religious instruction in the school building by volunteer religious teachers (*McCollum* v. *Board of Education*, 333 U.S. 203), but in 1952 it upheld a similar New York plan which differed only in that the religious instruction took place off the school property (*Zorach* v. *Clauson*, 343 U.S. 306). Attempting to define in this case what was forbidden by the establishment of religion clause, Justice Douglas wrote:

"Government may not finance religious groups nor undertake religious instruction nor blend secular and sectarian education nor use secular institutions to force one or some religion on any person. . . . It may not make a religious observance compulsory. It may not coerce anyone to attend church, to observe a religious holiday, or to take religious instruction."

Civil Liberties and Criminal Prosecutions.—Some idea of the importance for civil liberties of fair procedures in criminal prosecutions can be gained from the fact that half of the ten amendments making up the Bill of Rights—the 4th through the 8th—deal with this subject. These amendments, which apply to prosecutions in federal courts only (*Barron* v. *Baltimore*, 7 Pet. 243, 1833), protect against unreasonable searches and seizures, require grand jury indictment and trial by jury, guarantee assistance of counsel, and prohibit double jeopardy, self-incrimination, excessive bail and cruel and unusual punishment.

Of these protections, perhaps the one giving rise to greatest difficulty in enforcement has been the search and seizure provision of the 4th amendment. This barrier to invasion of personal privacy was erected because of experience with the infamous "general writs of assistance" under which the British authorities invaded private homes during the colonial period, and was based on the belief that "a man's home is his castle." Law enforcement officers consequently can enter a home only after securing a search warrant, which requires going before a judicial officer and giving a justification of the proposed search. When arresting a person under a warrant or for a crime committed in their presence, law officers can seize evidence which is in plain sight. Whether a search of the arrested party's premises is constitutional has been left uncertain by supreme court decisions (*Harris* v. *United States*, 331 U.S. 145, 1947; *Trupiano* v. *United States*, 334 U.S. 699, 1948; *United States* v. *Rabinowitz*, 339 U.S. 56, 1950).

Tapping of telephone wires which does not involve an actual entry into private quarters was declared by the supreme court in 1928 not to constitute unreasonable search and seizure, though Justice Holmes condemned it as a "dirty business" (*Olmstead* v. *United States*, 277 U.S. 438). However, congress made evidence secured by wire tapping inadmissible in federal courts. In 1954 congress defeated a bill which would have admitted wire-tapped evidence in federal court cases involving national security or kidnapping.

So far as criminal prosecutions in state courts are concerned, the guiding constitutional principle is the mandate of the 14th amendment that no state shall "deprive any person of life, liberty, or property, without due process of law; nor deny to any person within its jurisdiction the equal protection of the laws." The supreme court has ruled that "due process" does not necessarily include all the protections specified in the 4th through the 8th amendments (*Adamson* v. *California*, 332 U.S. 46, 1947). Thus a state is not bound to require indictment by grand jury, nor to grant trial by a 12-man common law jury, nor to avoid double jeopardy or self-incrimination. States must, however, give such protections as are "of the very essence of a scheme of ordered liberty" (*Palko* v. *Connecticut*, 302 U.S. 319, 1937). Specifically, this means that they must grant counsel in capital cases, there must not be systematic racial discrimination in selection of juries, confessions are invalid if extorted by force, unreasonable searches and seizures are unconstitutional, and in general the requirements of a fair hearing must be observed.

Liberty as Means or as End?—Whether liberty be an end in itself or a means (indispensable or not) to other ends has often been debated. Libertics, in the sense here used, have always been used as means toward freedom or power. Civil, political, economic and academic freedoms have been considered by some as ultimate values. Close examination of actual situations, however, shows many in which legal liberty has been invoked to permit a freedom, but the freedom is used to seek some ulterior satisfaction better described in terms of other values such as self-expression, personality, power, prestige, wealth, beauty, truth, good conscience, good will, peace, security, progress, pleasure or the common welfare.

The feeling of freedom is a satisfaction so precious to many people that (paradoxically) they will give up much welfare, many liberties, even such rights as guarantee their freedom, if they feel that in doing so they are free, or imagine they are thus ultimately protecting their freedom.

It is frequently said that, in modern war, liberties must be suspended in order to protect "liberty." Such a formula assumes: (1) that criticism hinders war effort; (2) that after victory both the people and their then rulers will retain enough attachment to the values of civil liberties to offset more immediate and selfish interests; and (3) that the political mechanisms for restoration of liberties are preserved.

Legal liberties may be claimed for the underprivileged by those whose interests lie in exploiting those liberties; *e.g.*, labour legislation has been opposed by employers in the name of "free contract" and "equality before the law." Groups obviously devoted to programs destructive to civil liberty may use the present protection of the Bill of Rights to forward their "subversive" doctrines. These are risks which apparently must be assumed if the rights are to be preserved in the interests of other persons and groups and of the community as a whole.

Modern rationalization of civil liberties is not altogether in terms of individualism. They are defended not merely as ends but as means to the organic welfare of a nation, in which persons and community are

mutually constituted facts in a total situation and equally indispensable. There is a diversity of gifts and roles, and all have a "right to each other's differences." Where liberties are denied, society as a whole is deprived, not only of the extreme expressions that have been penalized, but of the wiser oppositions and variants that have thereby been deterred.

Perhaps the most eloquent modern statement of the philosophy of freedom of thought is found in Justice Holmes's dissenting opinion in *Abrams* v. *United States* (250 U.S. 616):

"Persecution for the expression of opinions seems to me perfectly logical. If you have no doubt of your premises or your power and want a certain result with all your heart you naturally express your wishes in law and sweep away all opposition. To allow opposition by speech seems to indicate that you think the speech impotent, as when a man says that he has squared the circle, or that you do not care wholeheartedly for the result, or that you doubt either your power or your premises. But when men have realized that time has upset many fighting faiths, they may come to believe even more than they believe the very foundations of their own conduct that the ultimate good desired is better reached by free trade in ideas—that the best test of truth is the power to get itself accepted in the competition of the market, and that truth is the only ground upon which their wishes safely can be carried out. That at any rate is the theory of our Constitution."

(T. D. E.; C. H. P.)

CIVIL LIST, the English term for the account in which are contained all the expenses immediately applicable to the support of the British sovereign's household and the honour and dignity of the crown. An annual sum is settled by the British parliament at the beginning of the reign of the sovereign and is charged on the consolidated fund. But it was only from the reign of William IV that the sum thus voted was restricted solely to the personal expenses of the crown. Before his accession many charges properly belonging to the ordinary expenses of government had been placed on the Civil List.

William and Mary.—The history of the Civil List dates from the reign of William and Mary. Before the Revolution no distinction had been made between the expenses of government in time of peace and the expenses relating to the personal dignity and support of the sovereign. The ordinary revenues, derived from the hereditary revenues of the crown and from certain taxes voted for life to the king at the beginning of each reign, were supposed to provide for the support of the sovereign's dignity and the civil government, as well as for the public defense in time of peace. Any saving made by the king in the expenditure touching the government of the country or its defense would go to swell his privy purse. But with the Revolution a step forward was made toward the establishment of the principle that the expenses relating to the support of the crown should be separated from the ordinary expenses of the state.

The parliament of William and Mary voted in 1689 an annual sum of £600,000 for the charge of the civil government. This was a mere resolution without statutory effect. In 1697 the first Civil List act was passed. Certain revenues (the hereditary revenues of the crown and a part of the excise duties), estimated to yield £700,000, were assigned to the king to defray the expenses of the civil service and the payment of pensions, as well as the cost of the royal household and the king's own personal expenses or privy purse. The Civil List meant practically all the expenses of government except the debt charge and defense. If the yield of the assigned revenues exceeded £700,000 the surplus was to be disposed of by parliament. This restriction was removed by an act of 1700. In the reign of Anne the Civil List consisted of the same assigned revenues (subject to certain deductions). The yield fell short of £700,000, and during the reign debts were incurred amounting to £1,200,000 which were paid off by parliament.

The Hanoverians.—For George I additional revenues were assigned, and it was enacted in effect that the Civil List should become independent of the yield of the assigned revenues and should be a fixed sum of £700,000 a year. Any surplus was to be surrendered and any deficiency would be made good. But this was found insufficient, and parliament from time to time made additional grants from the exchequer to pay off debts totalling £1,300,000. In the reign of George II there was again a change of system. The Civil List was composed of the assigned revenues, together with certain fixed grants, and a minimum yield of £800,000 was guaranteed by parliament. Any surplus yield over £800,000 was retained by the king. On the accession of George III the system of a fixed Civil List was resumed. The assigned revenues were no longer paid to the crown but to an aggregate fund as part of the revenues of the exchequer, and the fixed allowance of £800,000 was paid out of the aggregate fund to the king (subject to certain annuities payable to members of the royal family).

During the reign of George III the Civil List played an important part in the king's effort to establish the royal ascendancy. The "king's friends," his supporters in parliament, were lavishly rewarded with places, pensions and even bribes. There was no independent check upon the expenditure of the Civil List. As long as the total was not exceeded, the king, with the co-operation of complacent ministers, was free to spend as he pleased. As it turned out, despite stringent economies in the cost of the household, excesses were incurred. But parliament, already corrupted, was persuaded to provide extra funds to pay off the debts (£513,511 in 1769 and another £618,340 in 1777). In the latter year the Civil List was raised to £900,000.

Edmund Burke had already attacked the extravagance and corruption of the Civil List and in 1780 introduced bills embodying his scheme of economic reform. The scheme could not be passed against Lord North's government, but in 1782 the Rockingham ministry passed a Civil List act which abolished many useless offices, imposed restraints on the issue of secret service money, stopped secret pensions payable during the king's pleasure and provided for a more effectual supervision of the royal expenditure.

The Civil List was divided into classes, but estimates for the several classes were not binding and were in fact soon exceeded. Indebtedness accumulated and had from time to time to be paid off (£3,398,000 in all between 1782 and 1820). The amount of the Civil List itself was augmented and in 1816 it was fixed at £1,083,727. Meanwhile the principal provision for the civil government had come to be made outside the Civil List. Annual votes of parliament for what were called miscellaneous services had been between £200,000 and £300,000 in the earlier years of George III's reign and had been mainly casual and noncurrent. By 1820 they amounted regularly to about £2,000,000 a year. George IV on his accession in 1820 received a Civil List of £845,727.

On the accession of William IV in 1830, the Civil List was finally freed from all charges for the government service as distinguished from the court and royal family. The expenses left were covered by a Civil List of £510,000, including £75,000 for pensions.

Civil List Pensions.—The pensions were excluded from Queen Victoria's Civil List, which was reduced to £385,000 (separate provision of £100,000 being made for Queen Adelaide, who had had a privy purse of £50,000 during her husband's reign).

A new system of Civil List pensions was set up. The queen might, on the advice of her ministers, grant pensions up to a limit

of £1,200 in any one year, in accordance with a resolution of the House of Commons of Feb. 18, 1834, "to such persons as have just claims on the royal beneficence, or who, by their personal services to the crown, by the performance of duties to the public, or by their useful discoveries in science, and attainments in literature or the arts, have merited the gracious consideration of the sovereign and the gratitude of their country." In 1937 the limit of £1,200 was raised to £2,500, and in 1952 it was raised to £5,000.

Queen Victoria to Elizabeth II.—Queen Victoria's Civil List amounted to £385,000. The sums granted after 1901 were as follows:

	Edward VII	George V	Edward VIII	George VI	Elizabeth II
	1901	1910	1936	1937	1952
Privy purse	£110,000	£110,000	£110,000	£110,000	£ 60,000
Salaries and retired allowances of household	125,800	125,800	134,000	134,000	185,000
Expenses of household	193,000	193,000	152,800	152,800	121,800
Works	20,000	20,000	..	..	..
Royal bounty, alms and special service	13,200	13,200	13,200	13,200	13,200
Unappropriated	8,000	8,000	..	..	..
Supplementary provision	..	..	..	..	95,000
	£470,000	£470,000	£410,000*	£410,000	£475,000

*Of this amount £40,000 in respect of the king's possible marriage, and £79,000 representing the revenues of the duchy of Cornwall, were undrawn.

In the reigns of Edward VII, George V and George VI £40,000 was earmarked for the queen. In the reign of Elizabeth II £40,000 was paid to the duke of Edinburgh from the consolidated fund.

A new class for works introduced in 1901 was composed partly of an item previously included under expenses and partly of expenditure previously voted by parliament. The reduction in salaries was due to the abolition of the post of master of the buckhounds and some other reductions of establishments and emoluments. The allocation among classes was not absolutely binding, in that savings on one class could be applied to meet excesses on another (or added to the privy purse) with the consent of the treasury. The works class was an exception, savings upon it being accumulated for future years.

The Civil List acts, 1901–1937, made provision for an annuity of £70,000 to the widow of a sovereign. Queen Alexandra, Queen Mary and Queen Elizabeth drew this allowance.

No change was made either in the total or in the details on the accession of George V in 1910, but a slight change of practice was introduced. In 1842 Victoria, though under no legal or constitutional obligation to pay taxes of any kind, undertook voluntarily to pay income tax. Edward VII continued the voluntary payment. George V agreed with the government of the day that it should be discontinued, but in exchange placed on the Civil List the cost of state visits of foreign royalties previously defrayed from public funds. In 1916 the king made a voluntary gift of £100,000 toward the cost of World War I. In the financial crisis of 1931 George V voluntarily offered to make a reduction in the Civil List. It was not until July 1, 1935, that this economy cut was fully restored. In 1948 George VI transferred to the consolidated fund a sum of £100,000 which represented the savings on the Civil List during World War II. The transfer was made so that no additional charge should be imposed for a period of four years for the payments to Princess Elizabeth and the duke of Edinburgh. In addition to the Civil List the sovereign receives the revenues of the duchy of Lancaster. The revenues of the duchy of Cornwall belong to the prince of Wales as duke of Cornwall, but in the absence of a prince of Wales, as in the reigns of Edward VIII and George VI, they revert to the crown.

It has also been the practice for provision to be made for the sons and daughters of the sovereign. The heir apparent, if the only or eldest son of the king, is duke of Cornwall and as such possesses the revenues of the duchy, which in 1936 were £117,603 and in 1951 were £84,675. Edward, prince of Wales (later Edward VII), received the revenues of the duchy, then £60,000 a year, with the addition of £40,000 on marriage; the duke of York (later George V) £80,000, with the addition of £20,000; Edward, prince of Wales (later Edward VIII) £80,000. Prince Charles, duke of Cornwall, receives one-ninth of the revenues until he is 18 and then £30,000 a year until he is 21. He will then receive the entire revenue of the duchy.

Annual provision to other members of the royal family was made (in 1952) to: the duke of Edinburgh, £40,000; the duke of Gloucester, £35,000; the Princess Royal, £6,000; and Princess Margaret, £6,000. The Civil List act 1952 increased the allowance to Princess Margaret to £15,000 in the event of her marriage. From the supplementary provision of £95,000 in Queen Elizabeth's Civil List £25,000 was available for other members of the royal family (*e.g.*, the duchess of Kent and the countess of Athlone) who undertook official duties.

BIBLIOGRAPHY.—No books have been written dealing solely with the Civil List. Most books mentioned in the bibliographies to the articles GREAT BRITAIN and PARLIAMENT contain chapters on the Civil List.

Reports of the Select Committees on the Civil List; *Civil List Acts* (since the beginning of the century there have been acts of 1901, 1910, 1936, 1937, 1952); *Princess Elizabeth's and Duke of Edinburgh's Annuities Act, 1948; Crown Lands Abstract Accounts* (published annually). (R. G. H.; X.)

CIVIL SERVICE is the term used to describe servants of the state or central government employed as civilians. It does not cover ministers of the crown or members of the judiciary. In the United Kingdom it does not cover local government or municipal employees (*see* LOCAL GOVERNMENT), nor the staffs of public corporations such as the National Coal board and the Transport commission; but in some countries, where provincial administration forms part of the central government organization, some provincial staffs are civil servants. In the United States the term is often used to describe that part of the government service entered by examination and offering permanent tenure.

Throughout history all organized states have had civil servants, if not civil services. The civil service in China is undoubtedly the oldest. The able and powerful Roman civil service disappeared in the west when the empire broke up in the 4th and 5th centuries. In the modern world civil services became important with the formation of national states, notably in 17th-century France and Prussia.

Today the wide functions carried out by most modern states in the provision of social services (*e.g.*, insurance against unemployment or sickness) or the regulation of economic life, have brought into being large permanent civil services. Many civilians are also employed in support of the fighting services. The growth of these staffs is often described as "bureaucracy," a term which reflects the attitude of those who regret the tendency for the state to dominate the life of the individual. As against this, the personnel system of the big industrial organizations has tended to take on many of the characteristics of the civil service, while the industrial enterprises undertaken by the modern state have increasingly been modelled on the managerial experience of big business.

UNITED KINGDOM

The British civil service dates from a series of reforms between 1855 and 1875, associated with the names of Stafford Northcote and Charles Trevelyan. It was then that the principle was established that, in place of the system of departmental patronage hitherto in force, entry to the service should be by open competitive examination, carried out by an impartial body free from all political influence. For this purpose the civil service commission was set up in 1855. The high quality of recruits which resulted did much to ensure the high standard of the British civil service and to bring about a sense of unity, hitherto lacking, between the staffs of different departments.

The British civil service is unlike that in other countries in that there is no statute which regulates its constitution or organization. Pensions, indeed, are governed by statute, and some conditions of service laid down by orders in council, but the management of the civil service has been accepted as an executive function.

Every department of state has its own establishment and organization officer responsible for dealing with its own personnel problems. But the central responsibility for civil service questions (apart from recruitment) rests with the treasury which is

responsible for settling questions of salary and for the grading and organization of the different classes of civil servants (whether departmental classes or classes common to the service). The treasury generally supervises the execution of personnel policy by departments. Treasury control of personnel questions and of organization and methods developed gradually out of the treasury power of the purse.

Until 1943 the United Kingdom had separate diplomatic and consular services which staffed the embassies and legations, and the consulates, while the staff of the foreign office itself formed part of the home civil service. In that year the staffs of the foreign office, and of the embassies, legations and consulates and other overseas missions, were amalgamated into what became known as the foreign service, which had its own pension act and was a separate entity from the home civil service but had its recruitment also carried out by the civil service commission.

The main functions of the United Kingdom civil service are dealt with in the articles GOVERNMENT DEPARTMENTS, FOREIGN OFFICE, WAR OFFICE and ADMIRALTY.

The civil service is organized in a number of classes, themselves divided into grades. In what may be called the administrative-clerical field there are four main classes. The administrative class (numbering about 3,000 in the 1950s) is concerned with advice on broad questions of policy and with direction at the highest and most general levels. It forms the link between the political and executive agencies of government. The executive class (about 70,000) is responsible for the conduct of business within the framework of established policy and for extensive auditing, accounting and fiscal operations. The clerical class (140,000) performs simpler clerical functions, deals with particular cases in accordance with instructions, checks claims, collects material for statistical and other returns, and may interview members of the public on particular cases. The subclerical classes perform routine operations (about 100,000 in these and the typing grades).

Entrance to these classes is for the most part by open competitive examinations closely linked with the educational system. The age limits are: for the administrative class, 20½–24 years, *i.e.*, the university leaving age; for the executive class, 17½–19 years; and for the clerical class, 16–18 years. There is also a considerable flow of promotion from the clerical to the executive class and from the executive to the administrative. About half the members of the administrative class reach it by promotion.

The civil service also contains more than 110,000 professional, scientific, technical and ancillary staffs, organized in classes appropriate to the type of work to be performed, many of them common to the service. Examples are scientists engaged in research and development, lawyers or medical men acting as legal and medical advisers, architects and surveyors engaged in the design and construction of buildings, accountants, actuaries, etc. There is also a large group, more than 240,000, known as the minor and manipulative grades. The main members of this group are the manipulative grades in the post office, postmen, sorters, etc., numbering more than 200,000. This group also includes messengers.

Finally there is the industrial civil service, numbering about 420,000. This comprises skilled and nonskilled manual workers, below the level of foremen or supervisors, employed in government industrial establishments; *e.g.*, royal dockyards, royal ordnance factories, workshops, depots and stores. (Manual workers in the post office, however, though they do work of an industrial kind, are employed on nonindustrial conditions). Conditions in the industrial civil service are determined largely by reference to the principles of the fair wages resolutions of the house of commons, the effect of which is to impose on the government an obligation to observe conditions and hours not less favourable either than those established for the trade or industry concerned through the recognized negotiating machinery, or, where conditions are not so established, by other employers engaged in similar trades and industries. So in several important respects, industrial conditions are different from those in the nonindustrial civil service.

No person can be appointed to a permanent post in the civil service until he has satisfied the civil service commission of his suitability. The tests carried out by the civil service commission are not necessarily related to the specific duties to be performed. In the administrative-clerical field they are designed to secure a share of the best product of the universities and schools. Until World War I it was the practice to rely almost wholly on written examinations of a literary and academic nature. But later more reliance was placed on interviews at which the interview board had before them full particulars of the candidates' records. Much use is made of the interview in filling professional posts.

While recruitment is carried out centrally, promotion is for the most part departmental. There are, however, arrangements for the central pooling of a certain proportion of vacancies in certain grades so as to equalize chances of promotion, and interdepartmental transfers are commonly made when new departments are set up or existing departments need to be rapidly expanded. Further, for the top posts in all departments (permanent secretaries and deputy secretaries) the field of selection is the whole civil service. While appointments to these posts are made by the minister in charge of the department, the prime minister's assent is required for all promotions to these grades, and to posts of establishment officer and finance officer.

The British civil service prides itself on its impartiality and its capacity to give equally loyal and devoted service to ministers irrespective of which political party is in power. For many years no civil servant (other than industrial staff) has been allowed to become a candidate for parliament until he has resigned his civil service post. Further, there has long been a rule that no civil servant, save in the subordinate grades, is allowed to take any overt part in party politics. Originally this applied to all civil servants, with the exception of certain industrials, but in 1948 an independent committee, set up to examine the limitations on the political activities of civil servants, recommended that all minor, manipulative and industrial grades should be free to engage in political activities. This recommendation was accepted. In 1953 it was decided that while the ban on political activities must remain for the middle and higher ranks of the civil service, some measure of freedom in political activities (but not including parliamentary candidature) should be allowed to civil servants in the subclerical and clerical classes and in the lower reaches of the scientific and technical classes.

Civil service unions were recognized by the government from 1906 in the post office and from about 1912 in the rest of the civil service. In 1919 Whitley councils were set up to provide machinery for dealing with grievances and to give the staff a greater share in and responsibility for working conditions. There is a National Whitley council for the whole nonindustrial civil service and separate interdepartmental councils for each department. Each council has an official side appointed by the minister and a staff side, representatives of which are appointed by the civil service unions and associations which are recognized as representative of the staff interest concerned. These joint councils are negotiating bodies and can proceed only by agreement.

After World War I a system was set up for compulsory arbitration at the request of either the staff representatives or the official side about conditions of service such as emoluments, leave, etc. Disputes were to be referred by the ministry of labour to a tribunal consisting of an independent chairman appointed by the minister of labour, one member drawn from the panel of persons appointed by the minister of labour as representing the chancellor of the exchequer, and one member drawn from the panel of persons appointed by the minister of labour as representing the staff side of the National Whitley council. This system only applied to the conditions of service of civil servants receiving not more than £1,536 a year.

For the nonindustrial civil service the machinery for negotiation and joint consultation consists of joint councils, on which are represented the departments and trade unions concerned in each of the industrial groups; *e.g.*, engineering, shipbuilding or miscellaneous trades. The government, although a major industrial employer, is not represented on any of the negotiating bodies for outside industry. These councils are represented on a central body, known as the Joint Co-ordinating Committee for Government Industrial Establishment, which can deal with matters

brought before it by either side or with matters referred to it by the other councils. Unlike the National Whitley council, the Joint Co-ordinating committee does not deal with pay claims. Disputes affecting the industrial civil service that cannot be settled through this negotiating machinery are referred for arbitration to the industrial court, set up in 1919, which also deals with disputes in outside industry.

COLONIES AND COMMONWEALTH

Colonial Service.—Each of the British colonial territories has its own civil service paid from local funds voted by the local legislature. The colonial service is thus the aggregate of the civil services of the colonial territories. But the colonial service, besides being divided geographically into the civil services serving each colony, is also divided into separate services spread over the colonies as a whole. Thus, the colonial administrative service consists of all civil servants in the colonies carrying out duties corresponding roughly to the class of administrative civil servants at home. The higher administrative and professional ranks of the colonial service have been staffed almost entirely by people recruited in the United Kingdom and have been regarded in practice as an interchangeable service, eligible for promotion anywhere in the colonial service. The salaries and conditions of service vary between different territories, but there is some degree of uniformity in certain broad geographical areas. (E. E. Bs.)

Commonwealth.—*Australia.*—Each Australian state has its own civil service, based on the same general pattern as the central commonwealth civil service. The commonwealth civil service organization was provided for by the Public Service act, 1922–51, in conjunction with the Superannuation act, 1922–51, and the Public Service Arbitration act. Control is in the hands of a board of three members with semijudicial tenure. Appointments are in general competitive, at school-leaving and university standards; preference is given to ex-servicemen; there are no restrictions on interdepartmental or interstate movements.

Canada.—After long experience with patronage, Canada introduced an effective merit system in 1918 when an act strengthened the position of the civil service commission and laid down provisions for recruitment, promotion, dismissal and political rights. The Canadian system is based on the British pattern in that it is controlled by the treasury and has an administrative class recruited principally from the universities, but it follows the United States in its classification plan. Each province has a separate civil service.

Ceylon.—The civil service of Ceylon was founded in 1798 by the first British governor of Ceylon, Sir Frederick North, with the help of eight officers who went out with him and 24 more who were personally selected by the secretary of state.

In 1831 the first step was taken towards native staffing when the Colebrook commission recommended education for the natives in order that they might in time qualify for higher posts in the public service. In 1856 a general competitive examination held in London was substituted for the earlier Haileybury examination, and in 1891 a local division of the public service (known as the lower division) was established. Examination for this was held in Ceylon. After 1924, the competitive examination was held simultaneously in London and Ceylon, and in 1938 it was agreed that no more Europeans should be recruited. In 1931 a public service commission had been set up and in 1947, under the Soulbury constitution, it was made independent.

India.—The Indian civil service owed its early organization to Warren Hastings in 1772. It remained predominantly British in composition until 1920, but about half the officers in the service were Indians at the time of the transfer of power in 1947. The name of the service was then changed to the Indian administrative service, an Indian foreign service was set up and joined by many officers of the former I.C.S., and recruitment, previously based on a difficult university examination founded by Thomas Babington Macaulay and Benjamin Jowett, was placed in the hands of an Indian public service commission who introduced an all-India competitive examination. The service still provides district officers, who may be in charge of all public activities for an area of over 4,000 sq.mi., but unlike the old service it does not provide officers for the judiciary.

New Zealand.—Political control of the public service in New Zealand lasted until 1912, when the Public Service act introduced control by an independent commissioner (replaced in 1946 by a commission not exceeding three) whose functions included recruitment, training, classification and promotion. Recruitment is at two levels, post-primary and university, and promotion is by merit.

Pakistan.—Pakistan, at the time of its formation in July 1947, was faced with the problem of establishing and manning complete central and provincial governments. It was decided to form a strong centrally administered service controlled by the government and by a public service commission, with a separate foreign service from which diplomatic and consular posts would be filled. Recruitment was an urgent problem and numbers were made up by transferring officers from the former Indian civil service and from the defense and other services. In 1949, however, the commission instituted an open central superior services examination by which all appointments would be made.

In addition to the central civil service the provinces have their own civil services under the provincial civil service commission.

South Africa.—The civil service in South Africa was set up under the South Africa act, 1909, by which the four colonies—the Cape of Good Hope, Natal, the Orange River colony and the Transvaal—were united into the Union of South Africa. (In 1923, when South-West Africa was mandated to the Union, the same conditions were applied to its civil service.) By this act the central government departments performed the functions of the civil services of the colonies, but the colonies, thereafter known as provinces, were given full control over education, health, roads and local government. A public service commission was appointed on Aug. 1, 1912, and its constitution was further defined by the Public Service act of 1923. The financial aspects of control, after much dispute, were agreed between the treasury and the commission. The commission is only a recommendatory body, but its recommendations are protected by law and are seldom rejected by the ministers or administrators of the provinces, who are vested with the final power of the appointment, promotion and dismissal of civil servants. (X.)

OTHER COUNTRIES

France.—The most prominent characteristics of the French civil service were established after the Revolution; the revolutionary assemblies destroyed the traditional and complex organization of the *ancien régime* and, under the Napoleonic empire, a new framework was set up. It was based upon two main principles: uniform hierarchy and centralization. Later regimes maintained this new administrative structure but tried to adapt it to democratic evolution. Successive reforms, mainly at the end of the 19th century, developed local autonomy in the *communes* and the *départements*. Thus the citizens were enabled to take an active part in the management of public affairs by electing local assemblies. Permanent links were established between central services and local authorities through the *maire*, elected by the council of the commune, and the *préfet*, appointed by the government. The presence of a *préfet* in every *département* secured a permanent control upon all local decisions.

In the 20th century the civil service was affected by the development of administrative tasks which implied an increase in the number of civil servants. New ministries were created to rule over health, economy, housing, etc. The organization of the French civil service became so intricate that uniform regulation appeared necessary. Some laws and the constructive work of the *conseil d'état* began to establish a general statute which was completed and codified by several acts of 1945 and 1946. The French civil service is divided into classes which correspond, broadly speaking, to the British ones. At the upper level the *administrateurs civils* can be compared to the members of the administrative class. New regulations also settled a uniform hierarchy of wages.

The *administrateurs civils* are recruited by the École Nationale d'Administration whose students come directly from universities as well as from the lower classes of the civil service. Courses last

three years, the first year spent in local services and the last two in attending lectures and seminars in Paris. The competitive system is generally used for recruitment in all classes.

The statute of the French civil servants also determines their rights and duties. In 1946 the right to form *syndicats*, or unions, was recognized by the government and joint committees were created to deal with disciplinary questions and technical improvements. The regulation of the French civil service, despite its uniformity, is not as rigid as it may seem. Special safeguards exist in the way in which certain traditions have grown up about some parts of the organization. First, in the upper reaches of the civil service, special and important functions are assumed by the main bodies—*les grands corps*—principally by three bodies of control. The *conseil d'état* is both an administrative organ frequently consulted by the government and a tribunal for administrative cases. The *cour des comptes* is a court of financial control over public expenses. The *inspection des finances* is a service which comes round to inspect the accounting officers. These three bodies, by their prestige and traditions, constitute one of the most original features of the French civil service.

Secondly a peculiar importance has always been given to the good recruitment and working of some technical services. Some of the most important specialized schools were created at the beginning of the 19th century, such as the École Polytechnique for scientific careers and the École Normale Supérieure where many future professors in the universities are trained. (P. Vt.)

Germany.—The German civil service emerged out of feudalism under a succession of outstanding Prussian monarchs culminating with Frederick the Great (1740–86). Legally it was based partly on custom, partly on executive acts and partly on statutes. The foundations of the civil service of the German reich were laid by the Civil Service act of 1873; in addition, the German states had developed civil services of their own.

Up to 1933 the German civil service was characterized by high standards of competence, integrity and impartiality. Its prestige was high and it was closely supported by active citizen advisory groups in municipalities and rural communities. Partisanship was prevented partly by tradition and partly by the fact that conservative groups prevailed under the first reich. After 1920 the Socialists made some partisan inroads, and after 1933 the Nazis required active party membership from all civil servants. Under the Nazi regime the standard of integrity of the civil service suffered heavily, but its competence and efficiency remained high.

The Civil Service act of 1937 was based on the old German law, but a number of enactments were introduced by the Nazis with the purpose of strengthening Nazi rule and of eliminating several categories of "undesirable persons." After Hitler's abolition of the German states the 1937 act was applied to all civil servants.

In 1950 the German Federal Republic eliminated all National Socialist clauses from the law of 1937. Both the federal civil service and those of the *Länder* returned to the principles contained in the Weimar constitution of 1919 by which entry into the civil service is determined by ability, regardless of race, sex and political or religious ideas. Provision was made for legal protection of civil servants, the state accepts liability for their wrongful acts and freedom of association is allowed. Many of the German states which were re-established after World War II issued new laws for their civil servants.

There are in the German civil service four different classes: the administrative class, requiring a university education; the higher executive class, based on secondary education; and the executive and clerical classes, requiring only a primary education and before 1945 largely reserved for soldiers at the end of their military service. The vast majority of those preparing for the highest grade take a law course, including economics, history and political science. Applicants are then admitted for a training period of several years, during which they work at the courts and in civil administration. They finally take an examination called the *Grosse Staatsprüfung* under the direction of one of the boards set up in every *Land*. Applicants for technical, medical and other careers within the administrative class receive similar, but specialist training.

Friedrich, "The German Civil Service," in *Civil Service in the Modern State*, ed. by L. D. White (1930); F. M. Marx, "Civil Service in Germany," in *Civil Service Abroad* by L. D. White *et al.* (1935).

Republic of Ireland.—Recruitment to the civil service in the Republic of Ireland is governed by the Civil Service Regulation acts of 1924 and 1926 which empowered the government to appoint three commissioners. In general no person may be appointed to a permanent situation in the Irish civil service unless a certificate of his qualification for the situation has been issued by the commissioners. Under the Civil Service Regulation act, 1924, and the Ministers and Secretaries act, 1924, the control of remuneration and conditions of service generally is vested in the minister for finance.

The local appointments commission, a body parallel to the civil service commission, selects the senior staffs of local authorities. Other staffs are recruited by the county and city managers on behalf of their local authorities. In staff matters a manager is not controlled in detail by the elected council. The central government supervises the numbers, pay and qualifications of these staffs. (X.)

THE UNITED STATES

The history of the U.S. civil service falls into three periods. The high standards of integrity, nonpartisanship and permanence of tenure established by George Washington on the whole prevailed in the national government until 1829, although the states were less fortunate. The Tenure of Office act of 1820 put terms to some positions and under Andrew Jackson (1829–37) rotation in office, partisanship and personal favouritism introduced the spoils system on a national scale. The second period of party patronage and spoils endured, under mounting criticism from such men as Thomas A. Jenckes, George William Curtis, Dorman B. Eaton and Carl Schurz until 1883, the date of enactment of the present national civil service act. After 1883 there was a steady extension and refinement of the merit system, but patronage continued to play an important role in many states, counties and cities.

The character of the U.S. civil service system has been deeply affected by the democratic manners and aspirations of the people. The patronage system was defended because it was believed democratic; on the other hand, a permanent public service smacked of bureaucracy. Jackson spoke against the idea of property in office and the advantages of wide participation in office holding, the duties of which he said were relatively "plain and simple." Everyone, it is still held, should have an opportunity to compete in examinations, hence age limits were high or nonexistent (and in 1953 were abolished for many classes of federal positions); hence objections to educational prerequisites except for scientific and professional posts. The U.S. has no historic tradition such as that which underlies the civil service institutions of Great Britain and the European continent.

In the national government the principal advances after 1883 were the increasing coverage of the merit system both by legislation and executive order, culminating in the Ramspeck act of 1940; the classification of positions by duties and a systematic pay plan in 1923; a pension act, 1920; the development of progressive personnel practices in the Tennessee Valley authority after 1933; the extension of the merit system by act of congress in 1939 to state services receiving federal grants; further protection against political interference, by the Hatch acts of 1939 and 1940; statutory provision for veterans' preference in 1919 and 1944; and in 1947 an executive order concerning employee loyalty. The centre of interest had shifted from protection against patronage to improved management methods, although the former still remained a principal duty of civil service commissions.

In the mid-1950s the merit system included (1) more than 95% of all permanent federal employees, excluding emergency and temporary workers; (2) all state and county personnel receiving federal funds; (3) the state services generally in about 22 states; (4) county services generally in New York and Massachusetts, frequently in New Jersey and occasionally elsewhere, notably Los

Angeles (Calif.) county and Milwaukee (Wis.) county; (5) city services in more than 800 municipalities and the employees of more than 1,000 council-manager cities most of which had no civil service commissions; (6) police and fire departments generally.

The county services were still predominantly partisan. In some states and some large cities operating standards were low, the merit system being a form rather than reality. But such cities as Los Angeles, Cincinnati, Milwaukee and St. Paul had admirable records. The U.S. party system was not fully adjusted to a non-partisan public service and the process offered difficult problems.

The merit system also had to be adjusted to preference for veterans, which antedates civil service legislation. From 1920 to 1940 veterans of World War I received from 20% to 25% of federal positions filled by examination. The Veterans' Act of 1944 gave disabled veterans ten points in addition to their earned ratings and a place at the head of each register, five points to all other veterans and various further privileges. With about 15,000,000 veterans of World War II, the proportion of veterans in the federal service by the mid-1950s amounted to 60%. In some states and cities even more impressive benefits were granted; each jurisdiction makes its own rules.

The legal foundation for the national civil service is a considerable body of legislation, a mass of executive orders and commission and departmental rules; in a few states there are constitutional requirements for civil service. State-wide laws govern county and municipal civil services in some cases; in other cities are left a free hand. In many states there is a considerable body of judicial interpretation, a branch of the law of public officers.

The typical form of organization for the administration of civil service laws is a commission, usually comprising three persons of whom not more than two may belong to the same political party. There is a trend, however, toward either a single personnel director, or a commissioner with two associate commissioners concerned only with rules and hearings. The U.S. civil service commission is by far the largest of its kind, with a peacetime staff following World War II of about 3,000. Its principal divisions are concerned with examination, position classification, investigations, retirement records, loyalty determinations and appeals and review. A large field force is organized in 14 regional offices and many subordinate stations. Every federal department and establishment has, since 1938, a personnel office to deal with its own problems and with the civil service commission. The heads of these offices form the Federal Personnel council, a body reestablished in 1938 to facilitate exchange of experience and the formulation of policy. Regional personnel councils exist in the principal centres. In the Tennessee Valley authority personnel work is in charge of a director of personnel; in the council-manager cities the same pattern is common. There are no special civil service tribunals in the U.S. apart from the loyalty boards; but in the federal departments, since 1940, there are appeal boards (including a representative of the civil service commission) to hear appeals on efficiency ratings.

The examination system developed markedly after 1920. Traditionally examinations were of the essay or problem type or consisted of a demonstration of skill or strength. From the psychological laboratories came tests of "general intelligence" and aptitude which were progressively adapted to large-scale use. Most written examinations now given by the U.S. civil service commission are of the short-answer type. They are scored by an electric scoring machine which has greatly expedited operations and reduced costs. The short-answer form permits the progressive improvement of the reliability and validity of tests, and much experimental work has been done inside and outside of government.

Tests for higher positions usually comprise a rating of education and experience and an oral interview, rather than a written paper. Tests for positions requiring skill or strength are usually demonstrations by actual performance. Grades are recorded numerically and, although they are not infallible, they represent the most scientific standard yet achieved. Certification is normally made by sending the appointing officer three names from which he must select one; the others are returned to the register for future use. Federal examinations are announced in post offices, newspapers and, in case of shortage, by radio and other means. State and municipal examinations are widely publicized.

The classification of positions by duties was initiated in Chicago, Ill., 1910–12, to facilitate equal pay for equal work. The procedure is to develop an accurate, detailed specification of the duties appropriate to each type or class of position, to determine a scale of pay for such positions, and then to allocate each particular job to its proper class. Hundreds of classes of positions will be found necessary in a given jurisdiction. This systematic description and arrangement of positions by duties has been found fundamental to many personnel operations, especially the preparation of examinations, certification, efficiency ratings, promotions, transfers and layoffs. The responsibility for classification is usually vested in the civil service commission, sometimes in a finance office; it is valuable even where there is no examination plan. Classification plans are frequently published and are usually open to inspection if not published. By the mid-1950s no co-ordination of the classification plans of different jurisdictions had yet been established, one (but only one) of the causes for the inadequate personnel statistics of the U.S.

Promotion is by merit, ascertained frequently by examination in the lower grades, and reaching into such positions as division and bureau chiefs. There is considerable movement from cities and states into the federal system, little in the contrary direction. Important career possibilities exist in all the professional and scientific branches and in many of the administrative, specialized and clerical services. The foreign service was put on a career basis in 1924. It is independently administered by the state department. More attention was paid during the decade 1930–40 to training young persons for the public service and to further training of those already employed. Following a national conference at the University of Minnesota in 1930 many universities and colleges developed courses in public administration, public finance, psychology and personnel management. The U.S. civil service commission and the New York city civil service commission were especially successful in organizing examinations to take advantage of graduates of these courses. State and municipal governments meanwhile had organized training facilities for their employees on a part-time after-hours basis, especially for police, fire, utility and inspectional personnel. In 1935 the graduate school of the U.S. department of agriculture expanded its work from the scientific field into the social sciences, including management. Many programs were opened up for municipal employees, especially in Los Angeles at the University of Southern California. This movement represented a marked advance in developing a professional interest within the public service.

Less attention has been given in the U.S. civil service to the formal protection of rights of employees, due partly to a patronage background, partly to the characteristically frequent change of occupation by Americans and partly to the influence of the business tradition of freedom to hire and fire, as well as to public concern over the growth of bureaucracy. The federal law prescribes a written notice and opportunity for a reply in case of discharge, but no hearing. In many federal establishments there are administrative provisions for a hearing within the agency; and if an employee can come forward with proof that he was discharged for political or religious reasons, he can appeal to the civil service commission. A veteran can appeal to the commission on wider grounds. In some jurisdictions, such as Chicago, Ill., the civil service commission acts as a hearing board. In a few, such as Massachusetts, a discharged employee may secure a full judicial review of the law and the facts.

Executive order 9835 (1947) required a check of the loyalty of all federal employees and future applicants for employment. Agency and regional loyalty boards were established to make initial determinations on all the evidence as to whether there was reasonable ground to doubt the loyalty of employees or applicants, and a Loyalty Review board was set up to entertain appeals. In a service of more than 2,000,000 about 3,000 employees resigned under charges or investigation. About 350 employees and applicants were found upon hearing to be of doubtful loyalty and were refused employment. The system was sustained by the supreme court. A few analogous loyalty laws in some states and cities discovered few offenders.

The state department, the department of defense, the Atomic Energy commission and other "sensitive" agencies possess by law special authority for summary suspension and removal after hearing of employees deemed to be a security risk. Both loyalty and security requirements were induced by fear of sabotage and espionage in the interest of foreign governments.

Unions of public employees were first organized in the post office in the 1890s and were recognized by congress in 1912. Clerical employees formed the National Federation of Federal Employees in 1917 and other groups subsequently. Municipal organizations appeared in the larger cities about 1900; a few organizations of state employees preceded World War I, but they and county employees remained relatively unorganized despite efforts after 1940 by the American Federation of Labor and the Congress of Industrial Organizations. Fire fighters are nationally organized; police are often forbidden to form unions but may organize local social and benevolent associations. Teachers have a national federation.

The purposes of these organizations are to secure legislation extending the merit system, better scales of pay and working conditions, protection against arbitrary action and such benefits as group insurance, credit facilities and the like. They are free, as a rule, to affiliate with outside labour organizations but are restrained from taking an active part in politics. In recent years they sought recognition of a right to collective bargaining, written agreements and the majority union as

the sole bargaining agent. Except in the Tennessee Valley authority these claims had not been widely granted. Strikes of public employees are rare, one dramatic exception being the Boston police strike of 1919. Police are usually forbidden outside affiliation and the right to strike, a right which is rejected by the overwhelming majority of public employee unions. The Taft-Hartley act (1947) prohibited strikes of federal employees and a number of states subsequently enacted comparable laws.

The public services of the states vary extremely in their legal organization and standards of competence. As of the mid-1950s about half had formal merit systems, and some of these were indifferently administered. The number of states with merit systems steadily increases, nevertheless, and standards are steadily improving. The older type of bipartisan civil service commission predominates but Minnesota and other states have abandoned the commission in favour of a director of personnel. Functions are chiefly examination, classification and record keeping. Most states have pension plans for teachers, and an increasing number have state-wide pension plans for all employees, on a contributory basis. In New Jersey and Massachusetts the state commissions carry on work for counties. In California there has been notable co-operation between state, county and municipal civil service commissions. There is no co-ordination between state and local agencies and the U.S. civil service commission.

State civil service agencies have been handicapped in some instances by political opposition, by lack of funds and by inadequate leadership. During the 1930s substantial progress was made, however, both in extending the merit system and in introducing better methods.

Primary and secondary school teachers are subject to minimum standards of training fixed by law. They are required to hold a certificate, usually issued by a state examining agency. Appointments are made by local school boards without competitive or other formal examinations. After a probationary period, teachers acquire a protected tenure. They are a part of the merit system but not under the jurisdiction of civil service commissions.

In a country which has 106 cities with a population of 100,000 or more (1950 U.S. census), the municipal civil services are of great importance. Until 1900 municipal employees were usually political appointees with low standards of competence and at times of integrity. The muckraking era (1900-05) and the ensuing period of municipal reform wrought a great transformation, supported by the increasingly technical nature of municipal functions. Municipal civil service commissions were widely established before 1910; in 1953 there were more than 800 cities under the merit system. The introduction of the council-manager plan after 1908 gave a great impetus to the further improvement of municipal standards, although city managers have not favoured the independent, bipartisan civil service commission. Political influence in appointments and promotions has not been eliminated in many of the larger cities, but in the middle-sized and small cities it has lost any major significance. One handicap to the professionalization of the municipal services lies in the preference for local residents for appointment—a universal requirement for police, fire, inspectional and clerical services and a usual requirement even in technical and professional posts. The practice of outside appointments has, however, become well-established among city managers, school superintendents, health officers and city engineers.

For the purpose of exchanging experience, improving procedures and publishing reports, civil service commissions and agencies in 1906 formed the Civil Service Assembly of the United States and Canada, with headquarters in Chicago. This body holds an annual convention, furnishes technical advice, carries on research and publishes professional bulletins and the quarterly journal, *Public Personnel Review*.

Outlying Possessions.—In 1900 the act providing for civil government in Puerto Rico extended the civil service act and rules to it. The concept and procedures were unknown to the population, and the enforcement of high standards remained difficult. The P.R. civil service commission secures some technical aid from time to time from the U.S. commission. In 1900 the merit system was also introduced in Hawaii. The civil service commission has maintained close contacts with trends on the mainland. (L. D. W.)

AN INTERNATIONAL CIVIL SERVICE

The elements of an international civil service were first found in the Universal Postal union (1874–1875). The League of Nations and the International Labour office (I.L.O.) required a staff of experts and subordinate personnel numbering about 600 which took the form of a true international civil service. It drew most heavily on British, French and Swiss sources, but more than 40 states contributed members in response to the requirement that the staff should be recruited "on as wide a geographical basis as possible." There were no formal methods of selection for the higher personnel; the director-general depended on personal acquaintances and trustworthy recommendations. The staff fell into three divisions: the administrative, the supervisory and clerical, and the custodial and manipulative.

The main point of interest in an international civil service lies perhaps in the steps it takes to free itself from national loyalties. The League existed during a period of rampant nationalism and irreconcilable conflict, but its experience showed that a broad measure of international loyalty can be achieved, even under difficult conditions. The staff of the League was dispersed after 1939 but that of the I.L.O. was maintained, principally in Canada.

A much larger international civil service was required for the United Nations organization and the specialized agencies. In the United Na-

[illegible] ployees of the United Nations and the specialized agencies, paid exclusively from the funds of each of these organizations, are assigned duties by its head. They are subject to its discipline and owe it full responsibility. Valuable experience in international co-operation was obtained during World War II through the various combined boards and through the lend-lease organization.

CIVITA CASTELLANA (anc. *Falerii*), a town and episcopal see of the province of Viterbo, Italy, 45 mi. by rail north of Rome. Pop. (1951) 11,517 (commune). Mt. Soracte lies about 6 mi. to the southeast.

Falerii was one of the 12 chief cities of Etruria. Wars between Rome and the Falisci (*q.v.*) appear to have been frequent. At the end of the First Punic War, they rebelled, but were soon conquered (241 B.C.) and lost half their territory. The ancient city, built upon a precipitous hill, was destroyed and another built on a more accessible site in the plain. Thus the original city occupied the site of modern Civita Castellana and the Roman town was transferred 3 mi. to the northwest. After this time, Falerii hardly appears in history. There were bishops of Falerii up till 1033, when the desertion of the place in favour of the modern site began, and the last mention of it dates from A.D. 1064. The site of the original Falerii is a plateau, about 1,100 yd. by 400, not higher than the surrounding country (475 ft.) but separated from it by gorges over 200 ft. in depth, and connected with it only on the western side, which was strongly fortified with a mound and ditch. The rest of the city, of which the circuit was about 2,250 yd., was defended by walls constructed of rectangular blocks of tufa. They reached in places a height of 56 ft. and were 7 to 9 ft. thick. There were about 80 towers and 8 gates. Two of the gates and some 50 of the towers have been preserved, as well as the remains of four temples within the city. Almost the only edifice now standing within the walls is the 12th century abbey church of S. Maria.

CIVITAVECCHIA, a seaport town and episcopal see of Italy, province of Rome, 50 mi. N.W. by rail and 35 mi. direct from the city of Rome. The population was (1951) 31,933 (com-

mune). It is the ancient *Centum Cellae*, founded by Trajan. Interesting descriptions of it are given by Pliny the Younger and Rutilius. The modern harbour works rest on the ancient foundations, and near it was the cemetery of detachments of the fleets of Misenum and Ravenna. It was a strong populous place in the 6th century, but the Saracens destroyed it in 812. Leo IV built a new city for the refugees 8 mi. N.N.E. of Civitavecchia, where may be seen ruins of walls and streets and an inscription, that must have stood over a gate, recording its foundation. The people returned to the old town (whence the name Civitavecchia) in 889, but the new one continued as the castle of Cencelle until the 15th century. In 1508 Pope Julius II began the construction of the castle from the designs of Bramante, Michelangelo being responsible for the addition of the central tower. Under it lies a Roman house, possibly the port admiral's quarters. Pius IV added a convict prison. The arsenal was built by Alexander VII and designed by Bernini. Civitavecchia was the chief port of the papal state and has still a considerable trade. There are cement factories in the town, which will be considerably increased by the new electric railway to Orte, by which Terni (*q.v.*) is readily accessible. In 1926 ships to the number of 2,285, a total tonnage of 2,041,637, entered and cleared the port, and 789,921 tons of merchandise were imported (chiefly coal and cereals) and exported (chiefly salt) from the saltworks of Porto Clementino, southwest of Tarquinia. There is a thermal establishment in the town, and 3 mi. N.E. were the *Aquae Tauri*, warm springs; considerable remains of the Roman baths of the time of Trajan are still preserved there. About one mile west of these are hot springs (the *Ficoncella*), also known in Roman times. Five miles down the coast is the summer resort of S. Marinella, which has grown up and forms a part of the commune of Civitavecchia.

CLACKMANNAN, a civil parish, but the county town of Clackmannanshire, Scotland. Pop. (1931) 2,585. It lies near the north bank of the Forth, 2 mi. east of Alloa, with two stations on the L.N.E.R. Clackmannan tower is now a picturesque ruin, but at one time was the seat of a descendant of the Bruce family. The old market cross still exists, and close to it stands the stone that gives the town its name (Gaelic, *clach*, stone; Manann, the name of the district). About 1 mi. to the southeast is Kennet house, the seat of Lord Balfour of Burleigh, another member of the Bruce family. Coal is mined near Clackmannan, which, however, lost its industrial importance to Alloa (*q.v.*).

CLACKMANNANSHIRE, the smallest county in Scotland, bounded southwest by the Forth, west by Stirlingshire, northnortheast and northwest by Perthshire, and east by Fifeshire. Its land area is 34,927 ac., or 54.6 sq.mi. An elevated ridge, starting on the west, runs through the middle of the county, widening gradually till it reaches the eastern boundary, and skirting the alluvial or carse lands in the valleys of the Forth and Devon. Still farther north are the Ochil hills, which reach a height of 2,363 ft., a volcanic range of the Old Red Sandstone period, consisting mainly of basalts and andesites. A fault along their southern base brings down the Carboniferous strata, which occupy the southern part of the county. The rivers of importance are the Devon and the Black or South Devon. The first, noted in the upper parts for its scenery and trout fishing, runs through the county near the base of the Ochils, and falls into the Forth at the village of Cambus, after a winding course of 33 mi., although as the crow flies its source is only 5¼ mi. distant. The Black Devon, rising in the Cleish hills, flows westward in a direction nearly parallel to that of the Devon, and falls into the Forth near Clackmannan. It supplies power to mills and collieries; and its whole course is over the Carboniferous strata. The Forth is navigable as far as it forms the boundary of the county. The only lake is Gartmorn, which was dammed in order to furnish water to Alloa and power to mills.

Agriculture and Industries.—The soil is generally productive and well cultivated, though the greater part of the high ground between the carse lands on the Forth and the vale of Devon at the base of the Ochils on the north consists of inferior soils, often lying upon an impervious clay. Oats is the chief crop (2,410 ac. in 1938). The Ochils afford excellent sheep pasture. The average size of the 144 holdings in 1938 was about 102 ac. There is a small tract of moorland in the east, called the Forest, bounded on its northern margin by the Black Devon. Copper, silver, lead and other minerals have been discovered in small quantity in the Ochils, between Alva and Dollar. The Carboniferous strata belong mainly to the coal measures, forming a northern continuation of the Lanarkshire basin and including a number of valuable coal seams. Fire clay, sandstone and igneous rock are also worked. Coal is mined at Sauchie, Coalsnaughton, Devonside, Clackmannan and other pits. The spinning mills at Alloa and Clackmannan are active, Alloa yarns and fingering being famous; and woollen goods are largely manufactured at Alva, Clackmannan and Tillicoultry. Distilleries and breweries have a large export business. Minor trades include glass blowing, coopering, iron founding, shipbuilding and papermaking. Mentsrie near Alloa has a large furniture factory. The L.N.E.R. serves the whole county, while the L.M.S.R. has access to Alloa.

Population and Government.—The population was estimated in 1938 at 33,117. In 1931 Gaelic and English were spoken by 146 persons. The county, with part of Stirling, returns one member to parliament. Clackmannan (1931 pop. 2,585) is the county town, but is not classed as a small burgh, of which there are four—Alloa (est. 1938 pop. 13,436), Alva (3,986), Tillicoultry (3,136) and Dollar (1,428). There are two county districts. Clackmannan forms a sheriffdom with Stirling and Dumbarton shires, and a sheriff-substitute sits at Alloa. There is an exceptionally well-equipped secondary school in Alloa and a well-known academy at Dollar.

CLACTON-ON-SEA, a watering place and urban district in East Essex, England; 71 mi. E.N.E. from London by the L.N.E.R. Pop. (1938) 23,410. Area, 10.6 sq.mi. Clay cliffs of slight altitude rise from the sandy beach and face southeastward. In the neighbourhood, however, marshes fringe the shore. The church of Great Clacton, at the village 1½ mi. inland, is of Norman and later date. It is an important watering place for London.

CLADEL, LÉON (1835–1892), French novelist, was born at Montauban (Tarn-et-Garonne) on March 13, 1835. He made a reputation by his first book, *Les Martyrs ridicules* (1862), a novel for which Charles Baudelaire, whose literary disciple Cladel was, wrote a preface. His best novels are realistic pictures of peasant life in his native district of Quercy. They include: *Le Nommé Qouael* (1868), *Le Bouscassié* (1869), *Les Va-nu-pieds* (1873), a volume of short stories, and *N'a qu'un oeil* (1882). He died at Sèvres on July 20, 1892.

See *La Vie de Léon Cladel* (1905), by his daughter Judith Cladel, containing also an article on Cladel by Edmond Picard.

CLAIRAULT (or CLAIRAUT), **ALEXIS CLAUDE** (1713–1765), French mathematician, was born on May 7 or 13, 1713, at Paris. Under the tuition of his father, a teacher of mathematics, he made such progress that at twelve years of age he read before the French academy an account of the properties of four curves which he had discovered. His *Recherches sur les courbes à double courbure*, finished in 1729 and published 1731, procured his admission into the Academy of Sciences, although he was still below the legal age. In 1736, with P. L. Maupertuis, he went on the expedition to Lapland, for the purpose of estimating a degree of the meridian; and in 1743 he published his treatise *Théorie de la figure de la terre*, in which he promulgated the theorem known as "Clairault's theorem," which connects the gravity at points on the surface of a rotating ellipsoid with the compression and the centrifugal force at the equator. In 1750 he gained the prize of the St. Petersburg academy for his essay *Théorie de la lune;* and in 1759 he calculated the perihelion of Halley's comet. He also detected singular solutions in differential equations of the first order, and of the second and higher degrees. Clairault died at Paris on May 17, 1765.

CLAIRON, LA (1723–1803), French actress, whose real name was CLAIRE LERIS, was born at Condé sur l'Escaut, Hainaut, on Jan. 25, 1723, the natural daughter of an army sergeant. In 1736 she made her first stage appearance at the Comédie Italienne, in a small part in Marivaux's *Ile des esclaves*. After several years in the provinces she returned to Paris. Her life, meanwhile,

had been decidedly irregular, even if not to the degree indicated by the libellous pamphlet *Histoire de la demoiselle Cronel, dite Frétillon, actrice de la Comédie de Rouen, écrite par elle-même* (The Hague, 1746), or to be inferred from the disingenuousness of her own *Mémoires d'Hippolyte Clairon* (1798); and she had great difficulty in obtaining an order to make her début at the Comédie Française for which she had the courage to select the title-rôle of *Phèdre* (1743). During her 22 years at this theatre, dividing the honours with her rival Mlle. Dumesnil, she filled many of the classical rôles of tragedy, and created a great number of parts in the plays of Voltaire, Marmontel, Saurin, de Belloy and others. She retired in 1766 and trained pupils for the stage, among them Mlle. Raucourt. Goldsmith called Mlle. Clairon, "the most perfect female figure I have ever seen on any stage" (*The Bee*, 2nd No.); and Garrick, while recognizing her unwillingness or inability to make use of the inspiration of the instant, admitted that "she has everything that art and a good understanding with great natural spirit can give her."

CLAIRTON, a city of Allegheny county, Pennsylvania, U.S.A., on the Monongahela river, 20 mi. S.E. of Pittsburgh; served by the Pennsylvania, the Pittsburgh and West Virginia, the Baltimore and Ohio, the Bessemer and Lake Erie and the Union railways. It was formed in 1922 by the consolidation of the boroughs of Clairton, North Clairton and Wilson, which in 1920 had a combined population of 10,777. The city's population in 1950 was 19,418 and in 1940 was 16,381 by the federal census. Clairton has important manufactures of structural iron, steel, boiler tubes, river boats and barges and an immense by-product coke plant.

CLAIRVAUX, a village of N.E. France, in the department of Aube, 40 mi. E.S.E. of Troyes. Clairvaux (*Clara Vallis*) is situated in the valley of the Aube on the eastern border of the forest of Clairvaux. Its abbey, founded in 1115 by St. Bernard, became the centre of the Cistercian order. The buildings (*see* ABBEY) belong for the most part to the 18th century, but there is a large storehouse which dates from the 12th century.

CLAIRVOYANCE, a word used with several different meanings in spiritualism and psychical research. Sometimes it is used to denote transcendental vision of beings on another plane of existence, while F. W. H. Myers, in the glossary to his *Human Personality*, defines it as "the faculty or act of perceiving as though visually, with some coincidental truth, some distant scene." It is now, however, often used as a term complementary to and exclusive of telepathy (*q.v.*), to denote all forms of supernormal cognition where the percipient's knowledge is not derived from another mind, whether or not the knowledge is communicated as a visual impression. It is in this last sense that the word is used in the article on PSYCHICAL RESEARCH (*q. v.*).

CLAM, the name applied to many bivalve molluscs (*see* LAMELLIBRANCHIA) from the vice-like firmness with which the shell closes. In Scotland the name is usually applied to the scallop (*q.v.*), in England to species of *Mya* and *Mactra* especially the gaper, *Mya truncata*. In the United States the name has a wider use, but most commonly denotes *Venus mercenaria*, the quahog or hard clam, and *Mya arenaria*, the soft clam, both of which are of great importance as food, besides being extensively used by fishermen as bait. The hard clam is allied to the cockle (*q.v.*) and has a heavy shell which was used as shell-money (*see* WAMPUM) by the Indians. It is found in one to six fathoms of water off the Atlantic coast of North America from Florida to Cape Cod and also off New Brunswick. It is obtained by raking the bottom. Young specimens, known as "little necks," are sold in large numbers in New York. The soft clam is found mainly between the tide-marks and has a thin shell and long siphons. "Clam bakes," where clams are placed on heated stones with potatoes and other food, the whole being covered with sea-weed and left to cook, make a popular picnic in America. Atlantic clams have been transplanted to the Pacific coast of North America with great success, though there are several indigenous species there which are also known by this name. It is an interesting point that while both *Mya* and *Mytilus* (the sea mussel, *q.v.*) occur on both sides of the Atlantic, the former is not eaten in Europe, the latter not in America; furthermore, in the prehistoric "kitchen-middens," remains of *Mytilus* are found in Europe and of *Mya* in America, but not vice versa. The American "fresh-water clams" are fresh-water mussels (*Unionidae*). The giant among the North American clams is the gweduc or geoduck (pronounced guey-duck), *Panomya generosa*, whose shell attains a length of almost seven in. and whose siphons may be extended to almost five times that measure; it is confined to the coast from northern California to British Columbia. Its flesh is greatly esteemed.

Of other species to which the name clam is applied, the most noteworthy are the bear's paw clam (*Hippopus maculatus*) of the Indian ocean, with a beautiful ridged white shell, marked with spots of purplish-red; and the giant clam (*Tridacna gigas*) of the East Indies, the largest of all lamellibranchs; the actual animal may weigh 20 lb. and the shell nearly ¼ of a ton.

CLAMECY, a town of central France, capital of an arrondissement in the department of Nièvre, at the confluence of the Yonne and Beuvron and on the Canal du Nivernais, 36 mi. N.N.E. of Nevers. Pop. (1946) 5,455. In the early middle ages Clamecy belonged to the abbey of St. Julian at Auxerre; in the 11th century it passed to the counts of Nevers. After the capture of Jerusalem by Saladin in 1188, Clamecy became the seat of the bishops of Bethlehem, who till the Revolution resided in the hospital of Panthenor, bequeathed by William IV., count of Nevers. The town figured in the *coup d'état* of 1851.

The church of St. Martin, dates chiefly from the 13th, 14th and 15th centuries. The town has fulling and flour mills, with a small leather and chemical trade. Wine and cattle, and timber are important.

CLAN, a social group of fundamental importance in the social structure of many primitive societies. The most important character of the clan is its exogamy—*i.e.*, marriage within the clan is forbidden, and regarded as incest (*see* EXOGAMY). This tabu applies even to persons between whom no genealogical relationship can be traced. Although for scientific purposes the clan is defined as an exogamous group, the term is frequently used in popular literature for groups that are not exogamous, such as the tribe; and that rather vague entity, the Scottish clan, though sharing some of the characters of the clan, is not an exogamous group, whatever it may once have been. Partly for these reasons, American writers use the term "sib" instead of "clan." The clan is a unilateral group; that is to say, membership of the clan is determined, either by descent through the mother ("matrilineal clan," "mother-sib," or "clan," as it has been variously named) or by descent through the father ("patrilineal clan," "father-sib," or "gens"). This does not mean, however, that descent from some original ancestor can be traced, though belief in such descent is usually present. The clan, therefore, has only a slight resemblance to the family (*q.v.*) which necessarily contains members of more than one clan, though it is possible that the clan has evolved from the family by emphasis of one line of descent.

Although the clan is not a kinship-group—for kinship implies not only relationship by direct descent, but the ability to trace it genealogically—nevertheless, it is common for members of a clan to address one another by means of relationship-terms used between close kin, and this carries with it the same sort of social relations as we find between close kin, though in less degree. This is a natural result of the classificatory system of relationships which is frequently associated with it, but even in the absence of this system it is common for distant members of a clan to claim brotherhood with one another, and to feel that kind of solidarity found in the case of the family. This solidarity is a most striking character of the clan. The individual identifies himself with his clan in a peculiarly intimate way, so that clan-responsibility for the action of individual members is common. This unity of the clan frequently extends into the political and economic sphere.

The unity of the clan is frequently emphasized by the possession of a totem (*see* TOTEMISM). Where clans are much interspersed and widely diffused, clan-identity may thus be established and maintained, which even the classificatory system of relationships need not reveal. It is doubtful whether habitation

of a common territory is ever the common tie uniting members of a clan, but localized clans do sometimes occur, though it is probable that in such cases the localization is secondary, and the common tie is belief in common descent.

Not uncommon is a grouping of clans into wider units, the simplest form of this being a dual organization (*q.v.*) in which the clans are grouped into two exogamous divisions. It is also not uncommon for there to be a division of function between the clans of a tribe, occasionally economic, *e.g.*, in India, but more usually political or religious, *e.g.*, in some African kingdoms.

BIBLIOGRAPHY.—The clan is defined and discussed in general books on Sociology, such as W. H. R. Rivers, *Social Organization* (1924), R. H. Lowie, *Primitive Society* (1921), and E. Westermarck, *History of Human Marriage*, vol. ii. (1921). (W. E. A.)

CLANRICARDE, EARL OF, Irish title, held since 1916 by the marquess of Sligo. In 1543, Ulick (d. 1544) (*q.v.*), chief of the "MacWilliam Eighter" branch of the De Burgh family (*q.v.*), surrendered his territory lying in the neighbourhood of Galway to Henry VIII, receiving it back to hold, by English custom, as earl of Clanricarde and Lord Dunkellin. Richard, the 4th earl (1601–35), who fought on the English side in O'Neill's rebellion, obtained the English earldom of St. Albans in 1628, his son, Ulick (*q.v.*), receiving the Irish marquessate of Clanricarde in 1646; but at the death of the latter, without heirs, the English honours and the marquessate expired, and the Irish earldom went to his cousin, Richard, 6th earl (1657–66). The 9th earl, John, forfeited his estates for his support of James II but they were restored to him in 1702, and his great-grandson, the 12th earl, was created marquess in 1789. He left no son, but the marquessate was again revived in 1825 for Ulick, 14th earl, who was lord privy seal and was created Baron Somerhill, in the United Kingdom, in 1826. On the death of Hubert George, 2nd marquess (1832–1916), Ulick's son, all his honours became extinct, except the earldom of Clanricarde (*c.* 1800), which passed to his kinsman, the marquess of Sligo.

CLANRICARDE, ULICK DE BURGH (BOURKE or BURKE), 1st EARL OF (d. 1544), styled MacWilliam and Ne-gan or Na-gCeann (*i.e.*, "of the Heads," "having made a mount of the heads of men slain in battle which he covered up with earth"), was the son of Richard or Rickard de Burgh, lord of Clanricarde, by a daughter of Madden of Portumna, and grandson of Ulick de Burgh, lord of Clanricarde (1467–87), the collateral heir male of the earls of Ulster. Ulick de Burgh succeeded to the headship of his clan, exercised a quasi-royal authority and held vast estates in county Galway, in Connaught, including Loughry, Dunkellin, Kiltartan (Hilltaraght) and Athenry, as well as Clare and Leitrim. In March 1541, he wrote to Henry VIII, placing himself and his estates in the king's hands. The same year he was present at Dublin, when the act was passed making Henry VIII king of Ireland. In 1543, in company with other Irish chiefs, he visited the king at Greenwich, made full submission, undertook to introduce English manners and abandon Irish names, received a regrant of the greater part of his estates with the addition of other lands, was confirmed in the captainship and rule of Clanricarde and was created on July 1, 1543, earl of Clanricarde and baron of Dunkellin in the peerage of Ireland, with unusual ceremony. "The making of MacWilliam earl of Clanricarde made all the country during his time quiet and obedient," states Lord Chancellor Cusake in his review of the state of Ireland in 1553. He did not live long, however, to enjoy his new English dignities but died shortly after returning to Ireland about March 1544.

See R. Bagwell, *Ireland under the Tudors*, vol. i.; Gairdner's *Letters and Papers of Henry VIII.*

CLANRICARDE, ULICK DE BURGH (BOURKE or BURKE), MARQUESS OF (1604–1657 or 1658), son of Richard, 4th earl of Clanricarde, created in 1628 earl of St. Albans, and of Frances, daughter and heir of Sir Francis Walsingham, and widow of Sir Philip Sidney and of Robert Devereux, earl of Essex, was born in 1604. He was summoned to the House of Lords as Lord Burgh in 1628 and succeeded his father as 5th earl in 1635. He sat in the Short Parliament of 1640 and attended Charles I in the Scottish expedition. On the outbreak of the Irish rebellion Clanricarde had powerful inducements for joining the Irish—the ancient greatness and independence of his family, his devotion to the Roman Catholic Church, and strongest of all, the ungrateful treatment meted out by Charles I and Wentworth to his father, one of Elizabeth's most staunch adherents in Ireland, whose lands were appropriated by the crown and whose death, it was popularly asserted, was hastened by the harshness of the lord-lieutenant. Nevertheless at the crisis his loyalty never wavered. Alone of the Irish Roman Catholic nobility to declare for the king, he returned to Ireland, took up his residence at Portumna, kept Galway, of which he was governor, neutral, and took measures for the defense of the county and for the relief of the Protestants, making "his house and towns a refuge, nay, even a hospital for the distressed English." In 1643 he was one of the commissioners appointed by the king to confer with the Irish confederates and urged the wisdom of a cessation of hostilities in a document which he publicly distributed. He was appointed commander of the English forces in Connaught in 1644 and in 1646 was created a marquess and a privy councillor. He supported the same year the treaty between Charles I and the confederates, and endeavoured after its failure to persuade Preston, the general of the Irish, to agree to a peace; but the latter, being advised by Rinuccini, the papal nuncio, refused in December. Together with Ormonde, Clanricarde opposed the nuncio's policy; and the royalist inhabitants of Galway, having through the latter's influence rejected the cessation of hostilities arranged with Lord Inchiquin in 1648, he besieged the town and compelled its acquiescence. In 1649 he reduced Sligo. On Ormonde's departure in Dec. 1650 Clanricarde was appointed deputy lord-lieutenant, but he was not trusted by the Roman Catholics and was unable to stem the tide of the parliamentary successes. In 1651 he opposed the offer of Charles, duke of Lorraine, to supply money and aid on condition of being acknowledged "Protector" of the kingdom. In May 1652 Galway surrendered to the parliament, and in June Clanricarde signed articles with the parliamentary commissioners which allowed his departure from Ireland. In August he was excepted from pardon for life and estate, but by permits, renewed from time to time by the council, he was enabled to remain in England for the rest of his life, and in 1653 £500 a year was settled upon him by the Council of State in consideration of the protection which he had given to the Protestants in Ireland at the time of the rebellion. He died at Somerhill in Kent in 1657 or 1658 and was buried at Tunbridge.

The "great earl," as he was called, supported Ormonde in his desire to unite the English royalists with the more moderate Roman Catholics on the basis of religious toleration under the authority of the sovereign, against the papal scheme advocated by Rinuccini, and in opposition to the parliamentary and Puritan policy. There is no reason to doubt Clarendon's opinion of him as "a person of unquestionable fidelity . . . and of the most eminent constancy to the Roman Catholic religion of any man in the three kingdoms," or the verdict of Hallam, who describes him "as perhaps the most unsullied character in the annals of Ireland." (*See* also CLANRICARDE, EARL OF.)

Gardiner's *Hist. of the Civil War and of the Commonwealth; Cal. of State Papers, Irish*, esp. *Introd.* 1633–47 and *Domestic; Hist. mss. Comm., mss. of Marq. of Ormonde* and *Earl of Egmont.* (P. C. Y.)

CLANVOWE, SIR THOMAS, English 14th century poet, author of *The Cuckoo and the Nightingale*, long attributed to Chaucer. Little is known of Clanvowe, whose name is last mentioned in 1404. He figured at the courts of Richard II and Henry IV, and was one of the 20 knights who accompanied John Beaufort to Barbary in 1390. His name was discovered on the best of the mss. by Professor Skeat in editing *The Book of Cupid, God of Love, or the Cuckoo and the Nightingale.*

The historic and literary importance of *The Cuckoo and the Nightingale* is great. It is the work of a poet who had studied the prosody of Chaucer with more intelligent care than either Occleve or Lydgate, and who therefore forms an important link between the 14th and 15th centuries in English poetry. Clanvowe writes

with a surprising delicacy and sweetness, in a five-line measure almost peculiar to himself. Professor Skeat points out a unique characteristic of Clanvowe's versification, namely, the unprecedented freedom with which he employs the suffix of the final *-e*, and rather avoids than seeks elision. *The Cuckoo and the Nightingale* was imitated by Milton in his sonnet to the nightingale, and was rewritten in modern English by Wordsworth.

See also a critical edition of the *Boke of Cupide* by Dr. Erich Vollmer (Berlin, 1898).

CLAPARÈDE, JEAN LOUIS RENÉ ANTOINE ÉDOUARD (1832–1870), Swiss naturalist, was born at Geneva on April 24, 1832. He belonged to a French family, some members of which had taken refuge in that city after the revocation of the Edict of Nantes. In 1852 he began to study medicine and natural science at Berlin, where he was greatly influenced by J. Müller, who was then working on the Echinoderms. The latter part of his stay at Berlin he devoted, along with J. Lachmann, to the study of the Infusoria and Rhizopods. In 1862 he was chosen professor of comparative anatomy at Geneva. He died at Siena on May 31, 1870. His *Recherches sur la structure des annélides sédentaires* was published posthumously in 1873.

CLAPPERTON, HUGH (1788–1827), Scottish traveller in central Africa, was born at Annan, Dumfriesshire, and after some years in the merchant service was impressed into the navy. In 1817 he returned home with the grade of lieutenant, and in 1820 accompanied Oudney and Denham in the Government expedition to Bornu. From Bornu they set out to explore the Niger country. After Oudney's death at Murmur (Jan. 1824) Clapperton proceeded along to Kano and Sokoto, returning by way of Zatia and Katsena to Kuka, where he met Denham. An account of the travels was published in 1826 under the title of *Narrative of Travels and Discoveries in Northern and Central Africa in the years* 1822–1824.

Immediately after his return Clapperton was raised to the rank of commander, and sent out with another expedition to Africa. He landed at Badagry in the Bight of Benin, and started overland for the Niger on Dec. 7, 1825, having with him his servant Richard Lander (*q.v.*), Captain Pearce, R.N., and Dr. Morrison, navy surgeon and naturalist. Before the month was out Pearce and Morrison were dead of fever. Clapperton continued his journey, and, passing through the Yoruba country, in Jan. 1826 he crossed the Niger at Bussa, where Mungo Park had died 20 years before. In July he arrived at Kano. Thence he went to Sokoto, intending afterwards to go to Bornu. The sultan, however, detained him, and he died of dysentery near Sokoto on April 13, 1827. Clapperton was the first European to make known from personal observation the semi-civilized Hausa countries, which he visited soon after the establishment of the Sokoto empire by the Fula.

In 1829 appeared the *Journal of a Second Expedition into the Interior of Africa*, etc., by the late Commander Clapperton, with a biographical sketch of the explorer by Lieut.-Col. S. Clapperton. Lander, who had brought back the journal of his master, also published *Records of Captain Clapperton's Last Expedition to Africa . . . with the subsequent Adventures of the Author* (2 vols. 1830).

CLAQUE, an organized body of professional applauders in the French theatres (Fr. *claquer*, to clap the hands). The hiring of persons to applaud dramatic performances was common in classical times, and the emperor Nero, when he acted, had his performance greeted by a chorus of 5,000 soldiers. Jean Daurat, the 16th century French poet, bought up a number of tickets for a performance of one of his plays and distributed them gratuitously to those who promised publicly to express their approbation. In 1820 an office was opened in Paris for the supply of *claquers*, and any number of them could be ordered in a way similar to the ordering of "extras" for a motion picture production of the present day. These people were usually under a *chef de claque*, whose duty it was to judge where their efforts were needed and to start the applause. The *commissaires* were scattered among the audience and called the attention of their neighbours to the good points of the play. The *rieurs* were those who laughed loudly at the jokes. The *pleureurs*, generally women, feigned tears, by holding their handkerchiefs to their eyes. The *chatouilleurs* kept the audience in a good humour, while the *bisseurs* simply clapped their hands and cried *bis! bis!* to secure encores.

CLARA, SAINT (1194–1253), foundress of the Franciscan nuns, was born of a knightly family in Assisi in 1194. At eighteen she was so impressed by a sermon of St. Francis that she was filled with the desire to devote herself to the kind of life he was leading. She obtained an interview with him, and to test her resolution he told her to dress in penitential sackcloth and beg alms for the poor in the streets of Assisi. Clara readily did this, and Francis, satisfied as to her vocation, told her to come to the Portiuncula arrayed as a bride. The friars met her with lighted candles, and at the foot of the altar Francis shore off her hair, received her vows of poverty, chastity and obedience, and invested her with the Franciscan habit, 1212. He placed her for a couple of years in a Benedictine convent in Assisi until the convent at St. Damian's, close to the town, was ready. Her two younger sisters, and, after her father's death, her mother and many others joined her, and the Franciscan nuns spread widely and rapidly (*see* CLARES, POOR). The relations of friendship and sympathy between St. Clara and St. Francis were very close, and there can be no doubt that she was one of the truest heirs of Francis's inmost spirit. After his death Clara threw herself wholly on the side of those who opposed mitigations in the rule and manner of life, and she was one of the chief upholders of St. Francis's primitive idea of poverty (*see* FRANCISCANS). She was the close friend of Brother Leo and the other "Companions of St. Francis," and they assisted at her death. For 40 years she was abbess at St. Damian's, and the great endeavour of her life was that the rule of the nuns should be purged of the foreign elements that had been introduced, and should become wholly conformable to St. Francis's spirit. She lived just long enough to witness the fulfilment of her great wish, a rule such as she desired being approved by the pope two days before her death on Aug. 11, 1253.

The sources for her life are to be found in the Bollandist *Acta Sanctorum* on Aug. 11, and sketches in such *Lives of the Saints* as Alban Butler's. *See* also Wetzer und Welte, *Kirchenlexicon* (2nd ed.), art. "Clara." (E. C. B.)

CLARE, the name of a famous English family. The ancestor of this historic house, "which played," in Freeman's words, "so great a part alike in England, Wales and Ireland," was Count Godfrey, eldest of the illegitimate sons of Richard the Fearless, duke of Normandy. His son, Count Gilbert of Brionne, had two sons, Richard, lord of Bienfaite and Orbec, and Baldwin, lord of Le Sap and Meulles, both of whom accompanied William the Conqueror to England. Baldwin, known as "De Meulles" or "of Exeter," received the hereditary shrievalty of Devon with great estates in the West Country, and left three sons, William, Robert and Richard, of whom the first and last were in turn sheriffs of Devon. Richard, known as "de Bienfaite," or "of Tunbridge," or "of Clare," was the founder of the house of Clare.

Richard derived his English appellation from his strongholds at Tunbridge and at Clare, at both of which his castle-mounds still remain. The latter, on the borders of Essex and Suffolk, was the head of his great "honour" which lay chiefly in the eastern counties. Appointed joint justiciar in the king's absence abroad, he took a leading part in suppressing the revolt of 1075. By his wife, Rohese, daughter of Walter Giffard, through whom great Giffard estates afterwards came to his house, he left five sons and two daughters. Roger was his heir in Normandy, Walter founded Tintern Abbey, Richard was a monk, and Robert, receiving the forfeited fief of the Baynards in the eastern counties, founded, through his son Walter, the house of FitzWalter (extinct 1432), of whom the most famous was Robert FitzWalter, the leader of the barons against King John. Of this house, spoken of by Jordan Fantosme as "Clarreaus," the Daventrys of Daventry (extinct 1380) and Fawsleys of Fawsley (extinct 1392) were cadets. One of Richard's two daughters married the famous Walter Tirel.

Gilbert, Richard's heir in England, held his castle of Tunbridge against William Rufus, but was wounded and captured. Under Henry I., who favoured the Clares, he obtained a grant of Cardi-

gan and carried his arms into Wales. Dying about 1115, he left four sons, of whom Gilbert, the second, inherited Chepstow, with Nether-Gwent, from his uncle, Walter, the founder of Tintern, and was created earl of Pembroke by Stephen about 1138; he was father of Richard Strongbow, earl of Pembroke (*q.v.*). The youngest son Baldwin fought for Stephen at the battle of Lincoln (1141) and founded the priories of Bourne and Deeping on lands acquired with his wife. The eldest son Richard, who was slain by the Welsh on his way to Cardigan in 1135 or 1136, left two sons, Gilbert and Roger, of whom Gilbert was created earl of Hertfordshire by Stephen.

It was probably because he and the Clares had no interests in Hertfordshire that they were loosely and usually styled the earls of (de) Clare. Dying in 1152, Gilbert was succeeded by his brother Roger, of whom Fitz-Stephen observes that "nearly all the nobles of England were related to the earl of Clare, whose sister, the most beautiful woman in England, had long been desired by the king" (Henry II.). He was constantly fighting the Welsh for his family possessions in Wales and quarrelled with Becket over Tunbridge castle. In 1173 or 1174 he was succeeded by his son Richard as third earl, whose marriage with Amicia, daughter and co-heir of William, earl of Gloucester, was destined to raise the fortunes of his house to their highest point. He and his son Gilbert were among the "barons of the Charter." Gilbert, who became fourth earl in 1217, obtained also, early in 1218, the earldom of Gloucester, with its great territorial "Honour," and the lordship of Glamorgan, in right of his mother; "from this time the house of Clare became the acknowledged head of the baronage." Gilbert had also inherited through his father his grandmother's "Honour of St. Hilary" and a moiety of the Giffard fief; but the vast possessions of his house were still further swollen by his marriage with a daughter of William (Marshal), earl of Pembroke, through whom his son Richard succeeded in 1245 to a fifth of the Marshall lands including the Kilkenny estates in Ireland. Richard's successor, Gilbert, the "Red" earl, died in 1295, the most powerful subject in the kingdom.

On his death his earldoms seem to have been somewhat mysteriously deemed to have passed to his widow Joan, daughter of Edward I.; for her second husband, Ralph de Monthermer, was summoned to parliament in right of them from 1299 to 1306. After her death, however, in 1307, Earl Gilbert's son and namesake was summoned in 1308 as earl of Gloucester and Hertford, though only sixteen. A nephew of Edward II. and brother-in-law of Gaveston, he played a somewhat wavering part in the struggle between the king and the barons. Guardian of the realm in 1311 and regent in 1313, he fell at Bannockburn.

The earl was the last of his mighty line, and his vast possessions in England (in over 20 counties), Wales and Ireland fell to his three sisters, of whom Elizabeth, the youngest, wife of John de Burgh, obtained the "Honour of Clare" and transmitted it to her son William de Burgh, 3rd earl of Ulster, whose daughter brought it to Lionel, son of King Edward III., who was thereupon created Duke of Clarence, a title associated ever since with the royal house. The "Honour of Clare," vested in the crown, still preserves a separate existence, with a court and steward of its own.

Clare College, Cambridge, derived its name from the above Elizabeth, "Lady of Clare," who founded it as Clare Hall in 1347.

Clare County in Ireland derived its name from the family, though whether from Richard Strongbow, or from Thomas de Clare, a younger son, who had a grant of Thomond in 1276, has been deemed doubtful.

Clarenceux King of Arms, an officer of the Heralds' college, derives his style, through Clarence, from Clare.

CLARE, JOHN (1793–1864), English poet, known as "the Northamptonshire Peasant Poet," was born at Helpstone, near Peterborough. He was the son of a farm-labourer, and when he was 12 or 13 began to work on a farm himself, attending a school in the evenings. At 16 he fell deeply in love with Mary Joyce, the daughter of a prosperous farmer, who forbade her to meet her lover. Clare never forgot this first love, and in his periods of insanity, long after Mary's death, he used to hold conversations with her, under the delusion that she still lived and was his wife. He tried his hand at many trades, was gardener at Burghley park, enlisted in the militia, and in 1817 worked as a lime-burner; from his last place he was discharged for spending his working hours in distributing copies of a prospectus of a book of his poems, and he was obliged to accept parish relief. The prospectus failed to attract subscribers, but luckily in 1817 a bookseller at Stamford, named Drury, noticed one of Clare's poems, "The Setting Sun," by chance, and befriended the author, introducing him to John Taylor, the publisher of Keats and Shelley. Taylor published Clare's *Poems Descriptive of Rural Life and Scenery* (1820), which attracted great attention, and his *Village Minstrel and other Poems* (1821). The poet was now comparatively prosperous with an annuity of £45. obtained by the patronage of Lord Exeter and other subscribers; but in 1820 he had married Patty Turner, and a growing family made his income inadequate. *The Shepherd's Calendar* (1827) met with little success, and Clare started farm labour again. Worry and overwork made him seriously ill. Earl Fitzwilliam gave him a new cottage and a piece of ground in 1832 but Clare could not settle down; gradually his mind gave way. He was still writing verse, but his last work, the *Rural Muse* (1835), was noticed by "Christopher North" alone. For some time he had shown signs of insanity; and in 1837, in spite of the efforts of his wife to prevent outside interference, he was removed to a private asylum. He seemed happy there, but after a time decided to go home, and set out to walk all the way. Then he was taken to the Northampton general lunatic asylum, where he remained, amusing himself by writing poetry, until his death.

BIBLIOGRAPHY.—The Oxford ed. of his *Poems* (1920), was ed. by Edmund Blunden and Alan Porter; his *Madrigals and Chronicles* by Edmund Blunden (1924). Both these eds. contain biographical introductions. *See* also F. Martin *The Life of John Clare* (1865); and J. L. Cherry *Life and Remains of John Clare* (1873).

CLARE, JOHN FITZGIBBON, 1ST EARL OF (1749–1802), lord chancellor of Ireland, the second son of John Fitzgibbon, was educated at Trinity college, Dublin, where he was highly distinguished as a classical scholar, and at Christ Church, Oxford, where he graduated in 1770. In 1772 he was called to the Irish bar. In 1778 he entered the Irish House of Commons as member for Dublin university, and at first gave a general support to the popular party led by Henry Grattan (*q.v.*). He was, however, from the first hostile to that part of Grattan's policy which aimed at removing the disabilities of the Roman Catholics; he endeavoured to impede the Relief bill of 1778 by raising difficulties about its effect on the Act of Settlement. As early as 1780 Fitzgibbon began to separate himself from the popular or national party by opposing Grattan's declaration of the Irish parliament's right to independence. His hostility to the Catholic claims, and his distrust of parliamentary reform as likely to endanger the connection of Ireland with Great Britain, made him a sincere opponent of the purposes which Grattan had in view. Grattan supported the appointment of Fitzgibbon as attorney-general in 1783, and in 1785 the latter highly eulogized Grattan's character and services to the country in a speech in which he condemned Flood's volunteer movement. He also opposed Flood's Reform bill of 1784; and from this time forward he was in fact the leading spirit in the Irish Government, and the stiffest opponent of all concession to popular demands. In 1784 the permanent committee of revolutionary reformers in Dublin, of whom Napper Tandy was the most conspicuous, invited the sheriffs of counties to call meetings for the election of delegates to attend a convention for the discussion of reform; and when the sheriff of the county of Dublin summoned a meeting for this purpose Fitzgibbon procured his imprisonment for contempt of court, and justified this procedure in parliament, though Lord Erskine declared it grossly illegal. In the course of the debates on Pitt's

commercial propositions in 1785, which Fitzgibbon supported in masterly speeches, he referred to Curran in terms which led to a duel between the two lawyers, when Fitzgibbon was accused of a deliberation in aiming at his opponent that was contrary to etiquette. His antagonism to Curran was life-long and bitter, and after he became chancellor his hostility to the famous advocate was said to have driven the latter out of practice. In Jan. 1787 Fitzgibbon introduced a stringent bill for repressing the Whiteboy outrages. His influence with the majority in the Irish parliament defeated Pitt's proposed reform of the tithe system in Ireland, Fitzgibbon refusing even to grant a committee to investigate the subject. On the regency question in 1789 Fitzgibbon, in opposition to Grattan, supported the doctrine of Pitt in a series of powerful speeches which proved him a great constitutional lawyer; he intimated that the choice for Ireland might in certain eventualities rest between complete separation from England and legislative union; and, while he exclaimed as to the latter alternative, "God forbid that I should ever see that day!" he admitted that separation would be the worse evil of the two.

In the same year Lord Lifford resigned the chancellorship, and Fitzgibbon was appointed in his place, being raised to the peerage as Baron Fitzgibbon. His removal to the House of Lords greatly increased his power. "He was," says Lecky, "by far the ablest Irishman who had adopted without restriction the doctrine that the Irish legislature must be maintained in a condition of permanent and unvarying subjection to the English executive." But the English ministry were now embarking on a policy of conciliation in Ireland. The Catholic Relief bill of 1793 was forced on the Irish executive by the cabinet in London, but it passed rapidly and easily through the Irish parliament. Fitzgibbon was opposed to the appointment of Lord Fitzwilliam (*q.v.*) as viceroy in 1795, and was probably the chief influence in procuring his recall; and it was Fitzgibbon who first put it into the head of George III. that the king would violate his coronation oath if he consented to the admission of Catholics to parliament. When Lord Camden, Fitzwilliam's successor in the viceroyalty, arrived in Dublin on March 31, 1795, Fitzgibbon's carriage was violently assaulted by the mob, and he himself was wounded; and in the riots that ensued his house was also attacked. In June 1795 he was created earl of Clare. On the eve of the rebellion he warned the Government to take stringent measures to prevent an outbreak; but he was neither cruel nor immoderate and was inclined to mercy in dealing with individuals. He attempted to save Lord Edward Fitzgerald (*q.v.*) from his fate by giving a friendly warning to his friend, and promising to facilitate his escape from the country. After the rebellion he threw his great influence on the side of clemency.

In Oct. 1798 Lord Clare, who since 1793 had been convinced of the necessity for a legislative union between Great Britain and Ireland, and was equally determined that the union must be unaccompanied by Catholic emancipation crossed to England and pressed his views on Pitt. In 1799 he induced the Irish House of Lords to throw out a bill for providing a permanent endowment Maynooth. On Feb. 10, 1800, Clare in the House of Lords moved the resolution approving the union in a long and powerful speech, in which he reviewed the history of Ireland since the Revolution, attributing the evils of recent years to the independent constitution of 1782, and speaking of Grattan in language of deep personal hatred. He was not aware of the assurance which Cornwallis had been authorized to convey to the Catholics that the union was to pave the way for emancipation, and when he heard of it after the passing of the act he bitterly complained that Pitt and Castlereagh had deceived him. After the union Clare became more violent than ever in his opposition to any policy of concession in Ireland. He died on Jan. 28, 1802.

Lord Clare was the first Irishman since the Revolution to hold the office of lord chancellor of Ireland. As a politician there is no doubt that his bitter and unceasing resistance to reasonable measures of reform did infinite mischief by inflaming the passions of his countrymen, driving them into rebellion, and perpetuating their political and religious divisions.

CLARE, a county in the province of Munster, Eire bounded north by Galway Bay and Co. Galway, east by Lough Derg, the river Shannon, and counties Tipperary and Limerick, south by the estuary of the Shannon, and west by the Atlantic Ocean. The area is 1,231 sq.mi. Pop. (1936) 89,879.

In the eastern mountains two masses of Old Red Sandstone with Silurian cores stand out, the more southerly of which, Slieve Bernagh, rises to a height of 1,746 ft. These masses are flanked by Carboniferous limestone which occupies the north and east of the county. The south-west is composed of Millstone Grit and Coal Measures which extend some distance into the interior. There are many lakes in the central lowlands and bogs are frequent on the higher land. In the southern part, along the banks of the Fergus and Shannon, are bands of rich low grounds called corcasses, of various breadth, indenting the land in a great variety of shapes. They are composed of deep rich loam, and are distinguished as the black corcasses, adapted for tillage, and the blue, used more advantageously as meadow land. The coast is rocky, and occasionally bold precipitous cliffs rise to a considerable height. There are numerous bays around the coast but Liscannor Bay provides the only safe anchorage on the Atlantic side. The River Fergus flows into the estuary of the Shannon, the creeks and bays of which render navigation safe in all winds.

The county, especially on the higher areas of the east and north, is very rich in dolmens. There still exist above a hundred fortified castles, mostly small, several of which are inhabited. Raths or encampments are to be found in every part. They are generally circular, composed either of large stones without mortar or of earth thrown up and surrounded by one or more ditches. The abbeys and other religious houses number more than twenty. Five round towers are to be found in various stages of preservation at Scattery Island, Drumcliffe, Dysert O'Dea, Kilnaboy and Inniscaltra (Lough Derg). The cathedral of the diocese of Killaloe is at the town of that name.

The county, together with part of the neighbouring district, was anciently called Thomond, that is, North Munster. Settlements were effected by the Danes, and in the 13th century by the Anglo-Normans, but without permanently affecting the possession of the district by its native proprietors. In 1543 Murrogh O'Brien submitted to Henry VIII., and received the title of earl of Thomond, on condition of adopting English dress, manners and customs. In 1565 this part of Thomond was added to Connaught, and made one of the six new counties into which that province was divided by Sir Henry Sidney. It was named Clare, the name being traceable either to Richard de Clare (Strongbow), earl of Pembroke, or to his younger brother, Thomas de Clare, who obtained a grant of Thomond from Edward I. in 1276. Towards the close of the reign of Elizabeth, Clare was detached from the government of Connaught and given a separate administration; but it was included with Connaught in Cromwell's schemes and suffered greatly as a result of his policy. At the Restoration it was united to Munster.

Metals and minerals have not been found in sufficient abundance to encourage commercial exploitation. The principal metals are lead, iron and manganese. The Milltown lead mine in the barony of Tulla is probably one of the oldest mines in Ireland and formerly there must have been a very rich deposit. Copper pyrites occurs in several parts of Burren in small quantity. Coal exists in Labasheeda on the right bank of the Shannon, but the few and thin seams are not productive. The nodules of clay-ironstone in the strata that overlie the limestone were mined and smelted as late as 1750. Within ½ mi. of the Milltown lead mine are natural vaulted passages of limestone. The lower limestone of the eastern portion of the county has been found to contain several very large deposits of argentiferous galena. Flags, easily quarried, are procured near Kilrush, and thinner flags near Ennistimon. Slates are

quarried in several places, the best being those of Broadford and Killaloe. Very fine black marble is obtained near Ennis; it takes a high polish, and is free from the white spots with which the black Kilkenny marble is marked.

The soil and surface of the county are in general better adapted for grazing than for tillage. Agriculture is in a backward state and little acreage is devoted even to the principal crops of oats and potatoes. Cattle, sheep, poultry and pigs, however, all receive considerable attention. Because of the mountainous nature of the county, nearly one-seventh of the total area is quite barren. There are no extensive manufactures, although flannels and friezes are made for home use, and hosiery of various kinds, chiefly coarse and strong, is made around Ennistimon and other places. There are several fishing stations but the rugged nature of the coast and the rough sea greatly hinder fishermen. Near Pooldoody is the great Burren oyster bed called the Red bank. Crabs and lobsters are caught in the Bay of Galway. In addition to the Shannon salmon fishery, eels abound in every rivulet and form an important article of consumption.

The Great Southern railway line from Limerick to Sligo intersects the centre of the county. From Ennis a branch runs to Ennistimon where it turns south and serves such watering places as Milltown Malbay, Kilkee and Kilrush. Killaloe is the terminus of a railway branch near the site of the Shannon power scheme (*see* SHANNON). Clare has five members in *dail eireann*.

CLAREMONT, a city of Sullivan county, New Hampshire, U.S., in the western part of the state, on the Connecticut river, at the mouth of Sugar river; served by the Boston and Maine railroad. The area is 6 sq.mi. Pop. (1950) 12,811. The falls of Sugar river (223 ft. within the town limits) furnish power for large factories, making shoes, paper, cotton and woollen goods and mining and quarrying machinery. Claremont is the shopping centre of an industrial region—mainly machine tool—including Springfield and Windsor, Vt., Newport, Lebanon and Lake Sunapee, N.H. First settled in 1762, the town was organized in 1764. It was named after Lord Clive's country place.

CLARENCE, DUKES OF. The early history of this English title is identical with that of the family of Clare, earls of Gloucester, who are sometimes called earls of Clare, of which word Clarence is a later form. The first duke of Clarence was Lionel of Antwerp (*see* below), third son of Edward III, who was created duke in 1362 and whose wife Elizabeth was a direct descendant of the Clares, the honour of Clare being among the lands which she brought to her husband. When Lionel died without sons in 1368 the title became extinct; but in 1412 it was revived in favour of Thomas (*see* below), the second son of Henry IV. The third creation took place in 1461, and was in favour of George (*see* below), brother of Edward IV. When this duke was attainted in 1478, his title was forfeited. There was no other creation of a duke of Clarence until 1789, when William, third son of George III, was made a peer under this title. Having merged in the crown when William became king in 1830, the title of duke of Clarence was again revived in 1890 in favour of Albert Victor (1864–92), the elder son of King Edward VII, then prince of Wales, only to become extinct for the fifth time on his death in 1892.

LIONEL OF ANTWERP, duke of Clarence (1338–1368), third son of Edward III, was born at Antwerp on Nov. 29, 1338. Before he was four years of age he was married to Elizabeth (d. 1363), daughter and heiress of William de Burgh, 3rd earl of Ulster (d. 1332), and he entered nominally into possession of her great Irish inheritance. Having been named as his father's representative in England in 1345 and again in 1346, Lionel was created earl of Ulster and joined (in 1355) an expedition into France, but his chief energies were reserved for the affairs of Ireland. Appointed governor of that country, he landed at Dublin in Sept. 1361. In Nov. 1362 he was created duke of Clarence and in the following year his father made an abortive attempt to secure for him the succession to the crown of Scotland. His efforts to secure an effective authority over his Irish lands were only moderately successful; and after holding a parliament at Kilkenny, which passed the celebrated statute of Kilkenny in 1366, he threw up his task in disgust and returned to England. At Milan, on May 28, 1368, he married Violante, only daughter of Galeazzo Visconti, lord of Pavia, who brought him a rich dowry. Some months were then spent in festivities, during which Lionel was taken ill at Alba, where he died on Oct. 17, 1368. His only child Philippa (1355–81), a daughter by his first wife, married in 1368 Edmund Mortimer, 3rd earl of March (1351–81), and through this union Clarence became the ancestor of Edward IV. The poet Chaucer was at one time a page in Lionel's household.

THOMAS, duke of Clarence, was born on Sept. 29, 1389. He paid two visits to Ireland, where he was nominally lord lieutenant from 1401 to 1413. For a short time, in 1412, he replaced his elder brother, afterward King Henry V, as the chief figure in the government. Clarence favoured an alliance with the Orléanist party and led an unsuccessful expedition to France in Aug. 1412. But, after Henry V's accession in 1413, the duke served his brother faithfully, and took part in the preparations for the French war. He was at the siege of Harfleur, but was invalided home before Agincourt, and acted as regent in 1416. During the invasion of Normandy, in 1417, Clarence led the assault to Caen, and, after Henry V's return to England in 1421, he remained in France as the king's lieutenant. He was killed at Baugé while rashly attacking the French and their Scottish allies on March 22, 1421. At the time of his death Clarence was heir to the throne. His marriage with Margaret Holland was childless and his titles became extinct.

GEORGE, duke of Clarence (1449–1478), younger son of Richard, duke of York, was born in Dublin on Oct. 21, 1449. Soon after his elder brother became king as Edward IV in March 1461, he was created duke of Clarence, and his youth was no bar to his appointment as lord lieutenant of Ireland in 1462. In 1466 Clarence was a suitor for the hand of Mary of Burgundy. Later he came under the influence of Richard Neville, earl of Warwick, and, in defiance of the king, was married to the earl's elder daughter, Isabel, at Calais in July 1469. With his father-in-law he supported the rebels in the north of England. When their treachery was discovered, Clarence fled to France in March 1470. Returning to England with Warwick in September, he supported the restoration of Henry VI, and the crown was settled upon himself in case the male line of the Lancastrian dynasty became extinct. But soon after Edward IV returned to England in March 1471, a public reconciliation between the brothers took place, and Clarence then fought for the Yorkists at Barnet and Tewkesbury. After Warwick's death in April 1471, Clarence claimed the whole of the vast estates of the earl, and in March 1472 was created by right of his wife earl of Warwick and Salisbury. However in 1474 Clarence had to accept a partition of the Warwick estates with his younger brother Richard, duke of Gloucester (later Richard III), who had married Warwick's younger daughter Anne. Isabel Neville died in Dec. 1476, and Clarence soon sought to marry, as his second wife, Mary of Burgundy, now duchess. To this marriage Edward IV objected. He became convinced that Clarence was aiming at his throne. The duke was thrown into prison, and in Jan. 1478 the king unfolded the charges against his brother to the parliament. He had slandered the king; had received oaths of allegiance to himself and his heirs; had prepared for a new rebellion; and was in short incorrigible. Both houses of parliament passed the bill of attainder, and the sentence of death which followed was carried out secretly in the Tower of London on Feb. 18, 1478. Soon after the event the rumour gained ground that he had been drowned in a butt of malmsey wine. Ambitious, weak and treacherous, Clarence lacked the ability of his brothers, Edward IV and Richard III. Two of the duke's children survived their father: Margaret, countess of Salisbury (1473–1541), and Edward, earl of Warwick (1475–99), who passed the greater part of his life in prison and was beheaded in Nov. 1499.

CLARENDON, EDWARD HYDE, 1ST EARL OF (1609–

1674), English statesman and the historian of the Great Rebellion, son of Henry Hyde of Dinton, Wiltshire, was born on Feb. 18, 1609. He entered Magdalen hall, Oxford, in 1622 (having been refused a demyship at Magdalen college), and graduated B.A. in 1626. In 1625 he entered the Middle Temple. At the university his abilities were more conspicuous than his industry, and at the bar his time was devoted more to general reading and to the society of eminent scholars and writers than to the study of law treatises. Among his friends were included Ben Jonson, John Selden, Edmund Waller, John Hales and especially Lord Falkland.

In 1629 he married Anne, daughter of Sir George Ayliffe, who died six months afterward; and secondly, in 1634, Frances, daughter of Sir Thomas Aylesbury, master of requests. In 1633 he was called to the bar and quickly obtained a good practice. His marriages had gained for him influential friends, and in Dec. 1634 he was made keeper of the writs and rolls of the common pleas. He was returned to the Short Parliament in 1640 as member for Wootton Bassett. The violations and perversions of the law which characterized the 12 preceding years of rule without parliament drove Hyde into the ranks of the popular party. He assailed the jurisdiction of the earl marshal's court, and in the Long Parliament, in which he sat for Saltash, renewed his attacks and practically effected its suppression. In 1641 he served on the committees for inquiring into the status of the Councils of Wales and of the North, and took an important part in the proceedings against the judges. He supported Strafford's impeachment and did not vote against the attainder, though he made subsequently an unsuccessful attempt through Essex to avert the capital penalty. Hyde's allegiance, however, to the Church of England was as staunch as his support of the law, and was soon to separate him from the popular party. He showed special energy in his opposition to the Root and Branch bill, and, though made chairman of the committee on the bill on June 11 in order to silence his opposition, he caused by his successful obstruction the failure of the measure. By the beginning of the second session he was regarded as one of the king's ablest supporters in the commons. He opposed the demand by the parliament to choose the king's ministers, and also the Grand Remonstrance, to which he wrote a reply published by the king.

He now definitely, though not openly, joined the royal cause but, in order to serve the king's interests more effectually, he refused to take office with John Colepeper and Falkland in Jan. 1642. Charles undertook to do nothing in the commons without the advice of these three. Nevertheless, a few days afterward, without their knowledge and by the advice of Lord Digby, he attempted the arrest of the five members, a resort to force which reduced Hyde to despair and which indeed seemed to show that things had gone too far for an appeal to the law. He persevered, nevertheless, in his legal policy, joined the king openly at York in June and continued to compose the king's answers and declarations in which he appealed to the "known laws of the land" against the arbitrary and illegal acts of a seditious majority in the parliament, his advice to the king being "to shelter himself wholly under the law . . . presuming that the king and the law together would have been strong enough for any encounter." Hyde's appeal had great influence, and gained for the king's cause half the nation. It by no means, however, met with universal support among the royalists, Hobbes jeering at Hyde's love for "mixed monarchy," and the courtiers expressing their disapproval of the "spirit of accommodation" which "wounded the regality." It was destined to failure because Charles was simultaneously carrying on another and an inconsistent policy, listening to very different advisers, such as the queen and Digby, and resolving on measures without Hyde's knowledge or approval.

In spite of Hyde's efforts war broke out. He was expelled from the house of commons on Aug. 11, 1642, and was one of those later excepted from pardon. He was present at Edge Hill, though not as a combatant, and followed the king to Oxford, residing at All Souls college from Oct. 1642 till March 1645. On Feb. 22, 1643, he was made a privy councillor and knighted, and on March 3 appointed chancellor of the exchequer. He was an influential member of the "Junto" which met weekly to discuss business before it was laid before the privy council. At the Uxbridge negotiations in Jan. 1645, where he acted as principal manager on the king's side, he tried to win individuals by promises of places and honours. He promoted the summons of the Oxford Parliament in Dec. 1643 as a counterpoise to the Long Parliament. Hyde's policy and measures, however, all failed. They had been weakly and irregularly supported by the king, and were fiercely opposed by the military party, which was urging Charles to trust to force and arms alone and eschew all compromise and concessions. Charles fell now under the influence of persons less affected by legal and constitutional scruples.

Hyde's influence was much diminished, and on March 4, 1645, he left the king for Bristol as one of the guardians of the prince of Wales and governors of the west. After Hopton's defeat on Feb. 16, 1646, at Torrington, Hyde accompanied the prince, on March 4, to Scilly, and on April 17, for greater security, to Jersey. He strongly disapproved of the prince's removal to France by the queen's order and of the schemes to restore the king with assistance from abroad, refused to accompany him and signed a bond to prevent Jermyn's scheme for the sale of Jersey to the French. He refused to compound for his own estate. While in Jersey he resided first at St. Helier and afterwards at Elizabeth castle with Sir George Carteret. He composed the first portion of his *History*, begun in Scilly, and kept in touch with events by means of an enormous correspondence. In 1648 he published *A Full Answer to an Infamous and Traitorous Pamphlet* . . . , a reply to the resolution of the parliament to present no more addresses to the king and a vindication of Charles.

On the outbreak of the second Civil War Hyde left Jersey (June 26, 1648) to join the queen and prince at Paris. He landed at Dieppe, sailed from that port to Dunkirk, and thence followed the prince to the Thames, where Charles had met the fleet, but was captured and robbed by a privateer and only joined the prince in September after the latter's return to The Hague. He strongly disapproved of the king's concessions at Newport. When the army broke off the treaty and brought Charles to trial he endeavoured to save his life, and after the execution drew up a letter to the several European sovereigns invoking their assistance to avenge it. Hyde strongly opposed Charles II's ignominious surrender to the Covenanters, the alliance with the Scots and the Scottish expedition, desiring to accomplish whatever was possible there through Montrose and the royalists and inclined rather to an attempt in Ireland. His advice was not followed and, as an excuse for retiring, he gladly accepted a mission with Cottington to Spain to obtain money from the Roman Catholic powers and to arrange an alliance between Owen O'Neill and Ormonde for the recovery of Ireland, arriving at Madrid on Nov. 26, 1649. The defeat, however, of the Scots at Dunbar and the confirmation of Cromwell's ascendancy influenced the Spanish government against Hyde and Cottington, and they were ordered to leave in Dec. 1650. Hyde arrived at Antwerp in June 1651, and in Dec. rejoined Charles at Paris after the latter's escape from Worcester. He now became one of his chief advisers, accompanying him in his change of residence to Cologne in Sept. 1654 and to Bruges in 1656, and was appointed lord chancellor on Jan. 13, 1658. His influence was henceforth maintained in spite of the intrigues of both Romanists and Presbyterians, as well as the violent and openly displayed hostility of the queen, and was employed unremittingly in the endeavour to keep Charles faithful to the church and constitution and in the prevention of unwise concessions and promises which might estrange the general body of the royalists. In 1656, during the war between England and Spain, Charles received offers of help from the latter power provided he could gain a port in England, but Hyde discouraged small isolated attempts. He expected much from Cromwell's death in 1658. In 1656 he made an alliance with the Levellers, and was informed of their plots to assassinate the protector, without apparently expressing any disapproval. He was well supplied with information from England and guided the action of the royalists with great ability and wisdom during the interval between Cromwell's death and the Restoration. He urged patience and advocated the obstruction of a settlement between the factions con-

tending for power and the fomentation of their jealousies rather than premature risings, though he did acquiesce in the abortive attempt of Aug. 1659.

The Restoration was a complete triumph for Hyde's policy. In his history he lays no stress on his own great part in it, but it was because of him that the Restoration was a national one, by the consent and invitation of parliament representing the whole people and not through the medium of one powerful faction enforcing its will upon a minority, and that it was not only a restoration of Charles but a restoration of constitutional monarchy. For by Hyde's advice concessions to the inconvenient demands of special factions had been avoided by referring the decision to a "free parliament," and the declaration of Breda reserved for parliament the settlement of the questions of amnesty, religious toleration and the proprietorship of forfeited lands.

Hyde entered London with the king and immediately obtained the chief place in the government. He retained the chancellorship of the exchequer till May 13, 1661, when he surrendered it to Lord Ashley. As lord chancellor he took his seat as speaker of the house of lords and in the court of chancery on June 1, 1660. On Nov. 3, 1660, he was made Baron Hyde of Hindon, and on April 20, 1661, at the coronation, Viscount Cornbury and earl of Clarendon, receiving a grant from the king of £20,000 and at different times of various small estates and Irish rents. He refused a large grant of land in the Fen country. By the marriage of his daughter Anne to James, duke of York, celebrated in secret in Sept. 1660, he became related to the royal family and the grandfather of two English sovereigns—Queen Mary and Queen Anne.

A rare occasion now offered itself of settling the religious question on a broad principle of comprehension or toleration; for the monarchy had been restored not by the supporters of the church alone but largely by the influence and aid of the Nonconformists and also of the Roman Catholics, who were all united at that moment by a common loyalty to the throne. Clarendon appears to have approved of comprehension but not of toleration. He had already in April 1660 sent to discuss terms with the leading Presbyterians in England, and after the Restoration offered bishoprics to several, including Richard Baxter. He drew up the royal declaration of October, promising limited episcopacy and a revised prayer book and ritual, which was subsequently thrown out by the convention, and he appears to have anticipated some kind of settlement from the Savoy conference which sat in April 1661. The failure of the latter proved perhaps that the differences were too great for compromise, and widened the breach. The parliament immediately proceeded to pass, between 1661 and 1665, the series of narrow and tyrannical measures against the dissenters known as the Clarendon code: the Corporation act, the Act of Uniformity, the Conventicle act and the Five-Mile act. Clarendon was not in fact the originator of these acts and in 1662 he sought to mitigate the effects of the Act of Uniformity. But his disapproval of the king's declaration in favour of indulgence (Dec. 26, 1662), and perhaps also of its probable author Arlington, drove him on to the side of the commons. He recorded his approval of the Conventicle and Five-Mile acts and ended by taking alarm at plots and rumours and regarding the great party of Nonconformists, through whose co-operation the monarchy had been restored, as a danger to the state whose "faction was their religion."

Meanwhile Clarendon's influence and direction had been predominant in nearly all departments of state. He supported the exception of the actual regicides from the indemnity, but only 10 out of the 26 condemned were executed, and Clarendon, with the king's support, prevented the passing of a bill in 1661 for the execution of 13 more. He upheld the Act of Indemnity against all the attempts of the royalists to upset it. The conflicting claims to estates were left to be decided by the law. The confiscations of the usurping government accordingly were cancelled, while the properly executed transactions between individuals were necessarily upheld. There can be little doubt that the principle followed was the only safe one in the prevailing confusion. The settlement of the church lands which was directed by Clarendon presented equal difficulties and involved equal hardships. In settling Scotland, Clarendon's aim was to uphold the English supremacy. He proposed to establish a council at Whitehall to govern Scottish affairs, and sought to restore episcopacy through the medium of Archbishop James Sharp. His influence, however, ended with the ascendancy of Lauderdale in 1663. In Ireland, while anxious for an establishment upon a solid Protestant basis, he urged "temper and moderation and justice" in securing it. He supported Ormonde's wise and enlightened Irish administration, and opposed the prohibition of the import of Irish cattle into England, incurring thereby great unpopularity. He was a member of the council for foreign plantations, and one of the eight lords proprietors of Carolina in 1663; and in 1664 sent a commission to settle disputes in New England. In the department of foreign affairs he had less influence. In 1664 he demanded, on behalf of Charles, French support and a loan of £50,000 against disturbance at home, thus initiating the ignominious system of pensions and dependence upon France. But he was the promoter neither of the sale of Dunkirk on Oct. 27, 1662, the author of which seems to have been the earl of Sandwich, nor of the Dutch war. He attached considerable value to Dunkirk, but when its sale was decided he conducted the negotiations and effected the bargain. He had concluded a treaty for the settlement of disputes with Holland on Sept. 4, 1662. But when hostilities were declared on Feb. 22, 1665, Clarendon gave his support to the war, asserted the extreme claims of the English crown over the British seas and contemplated fresh cessions from the Dutch and an alliance with Sweden and Spain. According to his own account he initiated the policy of the triple alliance, but it seems clear that his inclination toward France continued in spite of French intervention in favour of Holland; and he took part in the negotiations for ending the war by an undertaking with Louis XIV implying neutrality, while the latter seized Flanders. The crisis in this feeble foreign policy and in the general official mismanagement was reached in June 1667, when the Dutch burned several ships at Chatham.

The whole responsibility for the national calamity and disgrace was unjustly thrown on the shoulders of Clarendon. He was unpopular among all classes: among the royalists on account of the Act of Indemnity, among the Presbyterians because of the Act of Uniformity. Every kind of maladministration was currently ascribed to him, designs to govern by a standing army and corruption. He was credited with having married Charles purposely to a barren queen in order to raise his own grandchildren to the throne, with having sold Dunkirk to France, and his magnificent house in St. James's was nicknamed "Dunkirk house," while on the day of the Dutch attack on Chatham the mob set up a gibbet at his gate and broke his windows, holding him responsible for English lack of success in the war. He was disliked by the royal mistresses, whose favour he did not condescend to seek and whose presence often aroused his reproaches. Surrounded by such general and violent animosity, Clarendon's only hope could be in the support of the king. But Charles, long weary of the old chancellor's rebukes, was especially incensed at this time because of his failure to secure Frances Stuart (La Belle Stuart) for his seraglio—a disappointment which he attributed to Clarendon—and was now alarmed by the hostility which his administration had excited. He did not scruple to sacrifice at once the old adherent of his house and fortunes. By the direction of Charles, James advised Clarendon to resign before the meeting of parliament, but in an interview with the king on Aug. 26, 1667, Clarendon refused to deliver up the seal unless dismissed. On Aug. 30 he was deprived of the great seal, for which the king received the thanks of the parliament on Oct. 16. On Nov. 12 his impeachment was brought up to the lords, but the latter refused to order his committal on the ground that the commons had only accused him of treason in general without specifying any particular charge. Clarendon wrote humbly to the king asking for pardon and that the prosecution might be prevented, but Charles had openly taken part against him and, though desiring his escape, would not order or assist his departure for fear of the commons. Through the bishop of Hereford, however, on

Nov. 29 he pressed Clarendon to fly, promising that he should not during his absence suffer in his honour or fortune. Clarendon embarked the same night for Calais, where he arrived on Dec. 2. The lords, taking this as admission of guilt, immediately passed an act for his banishment and ordered the petition forwarded by him to parliament to be burned.

The rest of Clarendon's life was passed in exile in various parts of France. His sudden banishment entailed great personal hardships. On arriving at Calais he fell dangerously ill; and Louis XIV, anxious to propitiate England, sent him peremptory and repeated orders to quit France. At Evreux, on April 23, 1668, he was the victim of a murderous assault by English sailors, who attributed to him the nonpayment of their wages. For some time he was not allowed to see any of his children; even correspondence with him was rendered treasonable by the Act of Banishment.

Clarendon bore his troubles with great dignity and fortitude. He found consolation in religious duties, and devoted a portion of every day to the composition of his *Contemplations on the Psalms* and of his moral essays. He now finished his *History* and his *Autobiography*. Soon after reaching Calais he had written, on Dec. 7, 1667, to the University of Oxford, of which he was chancellor, desiring as his last request that the university should believe in his innocence and remember him, though there could be no further mention of him in their public devotions, in their private prayers.

He entertained to the last hopes of obtaining leave to return to England, but his petitions were not even answered or noticed. He died at Rouen on Dec. 9, 1674. He was buried in Westminster abbey a year later, at the foot of the steps leading to the Henry VII chapel. He left two sons, Henry, 2nd earl of Clarendon, and Lawrence, earl of Rochester, and a daughter Anne, duchess of York; a third son, Edward, having predeceased him.

As a statesman Clarendon had obvious limitations and failings. He brought to the consideration of political questions an essentially legal but also a narrow mind, conceiving the law, "that great and admirable mystery," and the constitution as fixed, unchangeable and sufficient for all time, in contrast with John Pym, who regarded them as living organisms capable of continual development and evolution. He was incapable of comprehending and governing the new conditions and forces created by the civil wars. His character, however, and therefore, to some extent, his career bear the indelible marks of greatness. He maintained his self-respect and dignity at a licentious court, and his integrity in an age of corruption. His industry and devotion to public business were rendered all the more conspicuous by the negligence, inferiority in business and frivolity of his successors. As lord chancellor Clarendon made no great impression in the court of chancery. His early legal training had long been interrupted, and his political preoccupations probably rendered necessary the delegation of many of his judicial duties to others. As chancellor of Oxford university, Clarendon promoted the restoration of order and various educational reforms. In 1753 his manuscripts were left to the university by his grandson Lord Cornbury, and in 1868 the money gained by publication was spent in erecting the Clarendon laboratory, the profits of the *History* having provided in 1713 a building for the university press adjoining the Sheldonian theatre, known since the removal of the press to its present quarters as the Clarendon building.

As a writer and historian Clarendon occupies a high place in English literature. His great work, the *History of the Rebellion*, is composed in the grand style. A characteristic feature is the wonderful series of well-known portraits, drawn with great skill and liveliness and especially praised by John Evelyn and by Macaulay. The book is, however, not well proportioned and is overloaded with state papers, misplaced and tedious in the narrative. The published *History* is mainly a compilation of two separate original manuscripts, the first being the history proper, written between 1646 and 1648, with the advantage of a fresh memory and the help of various documents and authorities, and ending in March 1644, and the second being the *Life*, extending from 1609 to 1660, but composed long afterward in exile and without the aid of papers between 1668 and 1670. The value of any statement, therefore, in the published *History* depends chiefly on whether it is taken from the *History* proper or the *Life*. In 1671 these two manuscripts were united by Clarendon with certain alterations and modifications, making books i–vii of the published *History*, while books viii–xv were written subsequently and, being composed for the most part without materials, are often inaccurate, with the notable exception of book ix, made up from two narratives written at Jersey in 1646, and containing very little from the *Life*. The inaccuracies are not the result of wilful misrepresentation but of failure of memory and of the disadvantages under which the author laboured in exile. In general, Clarendon, like many of his contemporaries, failed signally to comprehend the real issues and principles at stake in the great struggle, laying far too much stress on personalities and never understanding the real aims and motives of the Presbyterian party.

BIBLIOGRAPHY.—1. Editions of the *History:* The work was first published in 1702–04 from a copy of a transcript made by Clarendon's secretary, with a few unimportant alterations. This was the object of a violent attack by John Oldmixon for supposed changes and omissions in *Clarendon and Whitelocke Compared* (1727) and again in a preface to his *History of England* (1730). The charges were repelled and refuted by John Burton in the *Genuineness of Lord Clarendon's History Vindicated* (1744). The history was first published from the original by B. Bandinel, 8 vol. (Oxford, 1826), the best edition being that by W. D. Macray, 6 vol. (Oxford, 1888). *The Lord Clarendon's History . . . Compleated*, a supplement containing portraits and illustrative papers, was published in 1717, and *An Appendix to the History*, containing a life, speeches and various pieces, in 1724. The *Sutherland Clarendon* in the Bodleian library at Oxford contains several thousand portraits and illustrations of the *History*. *The Life of Edward, Earl of Clarendon . . . (and the) Continuation of the History . . .*, the first consisting of that portion of the *Life* not included in the *History*, and the second of the account of Clarendon's administration and exile in France, begun in 1672, was published in 1759, the *History of the Reign of King Charles II From the Restoration . . .*, published about 1755, being a surreptitious edition of this work, of which the latest and best edition is that of the Clarendon Press, 2 vol. (Oxford, 1857).

2. Other works: Among Clarendon's other works may be mentioned *A Brief View . . . of the Dangerous . . . Errors in . . . Mr. Hobbes's Book Entitled "Leviathan"* (1676); *The History of the Rebellion and Civil War in Ireland* (1719); *Essays Moral and Entertaining on the Various Faculties and Passions of the Human Mind* (pr. 2 vol., London, 1815, and in *British Prose Writers*, vol. i, 1819).

(London, 1838); Sir Charles Firth in *Dictionary of National Biography*, vol. xxviii (London, 1891), and his *Edward Hyde, Earl of Clarendon* (Oxford, 1909); Sir Henry Craik, *The Life of Edward, Earl of Clarendon*, 2 vol. (London, 1911).

CLARENDON, GEORGE WILLIAM FREDERICK VILLIERS, 4TH EARL OF (1800–1870), of the second creation, English statesman, was born in London on Jan. 12, 1800, and had—as Charles Greville once said—"the unspeakable advantage of being plain George Villiers, and having to fight his own way in the world," as a young man. He was at Christ's Hospital and at St. John's college, Cambridge. In 1820 Castlereagh appointed him attaché at St. Petersburg, where he served till 1823; but then lack of funds made him become a commissioner of customs, in which post he distinguished himself at Dublin and Paris. Strong intelligence, an agreeable presence and a gift for languages picked him out, and in 1833 Palmerston made him British ambassador at Madrid.

For six years he wrestled with the intricacies of Spanish politics, while the queen of Spain was a minor, the country torn by civil war, and his home government too preoccupied to afford him full support. In 1838 he succeeded an uncle as earl of Clarendon. Early in 1839 he returned to England and married. He refused to go to Canada as governor general, but was persuaded to enter Melbourne's cabinet as lord privy seal, becoming also chancellor of the duchy of Lancaster for the last few months of the government. This spell of office was chiefly notable for a painful opposition to a colleague, since Clarendon thought that Palmerston's policy on the Egyptian question was dangerously hostile to France; and he was delighted when the government resigned in 1841. He took the board of trade when the Whigs resumed office in 1846, and accepted a year later, reluctantly, the viceroyalty of Ireland, then in the throes of famine. He insisted on being armed with a coercion act, and so was able both to keep the

peace and to foster projects for relief. The land legislation he supported only crowded Ireland with selfish speculators; but this result was not apparent till after he had left office in 1852.

Early in 1853 Clarendon succeeded to the one post he coveted, and became the only professional diplomat ever to serve as foreign secretary. The foreign office staff took to him at once—he was known there, for many years after his death, as "the great Lord Clarendon"—but he found foreign affairs in confusion; he was never able to get his head clear of the mass of dispatches and could do nothing to stop the country "drifting" (the word was his) into the Crimean War. He was hampered by his own mistrust of Lord Stratford de Redcliffe, the ambassador at Constantinople, and by time-wasting interference from his prime minister, Lord Aberdeen, before the war began; and while it went on his talents for conciliation were mainly expended on keeping his colleagues in cabinet together. He had already secured the friendship of Napoleon III and was able by judicious argument face to face to persuade the emperor not to go to the Crimea himself. The French tired of the war before the British, and Clarendon had to use the full range of his diplomatic skill to secure a fair peace at Paris in March 1856. He was offered, but refused, a marquisate on its conclusion.

In 1858 he resigned with Palmerston's cabinet and did not rejoin him in 1859, partly since Lord John Russell insisted on having the foreign office himself and partly since Clarendon disagreed with the Italian policy on which the new government was founded. He had six years in retirement, advising his friends in office, rejoined them in 1864 as chancellor of the duchy of Lancaster, and became foreign secretary again on Palmerston's death in 1865. The fall of Russell's government released him after a few months, but he returned to the foreign office again, under Gladstone, at the end of 1868. He engaged in a wholly unsuccessful attempt, during the winter of 1869–70, to persuade Bismarck to reduce Prussian armaments; and died of overwork, just when Europe had most need of him, on June 27, 1870, three weeks before the outbreak of the Franco-German War. "If your father had lived," Bismarck said once to Clarendon's daughter Lady Emily Russell, "he would have prevented the war."

See Sir Herbert Maxwell, *Life and Letters of the Fourth Earl of Clarendon*, 2 vol. (London, 1913). (M. R. D. F.)

CLARENDON, HENRY HYDE, 2ND EARL OF (1638–1709), English statesman, eldest son of the historian, was born on June 2, 1638, and succeeded to the title on his father's death in 1674. James II made him lord lieutenant of Ireland (Sept. 1685) where he became an unwilling instrument of the king's desire to replace Protestants in high positions by Roman Catholics. He was recalled in Jan. 1687. At the time of the revolution he played a vacillating part, but opposed the settlement of the crown on William and Mary, and remained a nonjuror all his life. On June 24, 1690, he was arrested, by order of his niece, Queen Mary, on a charge of plotting against William, and though liberated for a time, was again imprisoned in Jan. 1691 on the evidence of Richard Graham, Lord Preston. He was released in July of that year, and from that time until his death, on Oct. 31, 1709, lived in retirement.

His public career had been neither distinguished nor useful, but it seems natural to ascribe its failure to small abilities and to the conflict between personal ties and political convictions which drew him in opposite directions, rather than, following Macaulay, to motives of self-interest. He was a man of some literary taste, a fellow of the Royal society (1684), the author of *The History and Antiquities of the Cathedral Church at Winchester, Continued by S. Gale* (1715), and the publisher, with his brother Rochester, of his father's *History* (1702–04).

He was succeeded by his only son, Edward (1661–1724), as 3rd earl of Clarendon; and, the latter having no surviving son, the title passed to Henry, 2nd earl of Rochester (1672–1753), at whose death without male heirs it became extinct in the Hyde line. (For the other Clarendon line, *see* above.)

CLARENDON, CONSTITUTIONS OF, 16 articles defining relations between church and king in England, which Thomas Becket, Roger, archbishop of York, and 12 bishops promised to observe at Clarendon (Jan. 1164) in the presence of Henry II, lay and other ecclesiastical magnates. The constitutions were presented as a simple record of some customs of the realm observed in the reign of Henry I. This was not exact, but there is little doubt that they were consonant with Henry I's claims, and that Henry II's purpose was to secure the liberties and dignities of his grandfather.

Controversy concentrated on three articles. Article 3 exposed clerics convicted on criminal charges in church courts to secular as well as ecclesiastical punishment, and left room for the trial of clerics on such charges in the king's court at its discretion. Trial of clerics in lay courts had become increasingly obnoxious to clergy during the previous hundred years as they inclined toward more exalted views of clerical status, but Becket's vehement opposition to double punishment of clerical felons was unusual. His objection was sanctioned by his death and miracles and formally enunciated by Pope Alexander III (about 1177). Henry II, after 1176, left clerics accused of common-law felonies to ecclesiastical trial and punishment. Article 4 prohibited clergy from leaving the realm without royal permission. Article 8 would have compelled an appellant from an archdeacon's court to appeal first to the bishop, then to the archbishop and only as a last resort and with royal permission to the pope. These restrictions had been made anachronistic by increasing resort to papal justice in a widening range of cases at all stages of litigation. Henry II abandoned them, with safeguards for royal rights, in 1172. Other controversial articles excluded from church courts litigation over debts and advowsons; prohibited excommunication of the king's immediate tenants and officials (both groups included clerics) without his consent; reserved to the king custody of the possessions of vacant sees and royal monasteries, and defined the procedure for filling the vacancies.

Important uncontroversial provisions rejected procedure on secret information against laymen in church courts, and excluded from church courts litigation over land held in lay fee.

With the exceptions noted, the constitutions were maintained in principle by Henry II and his successors, despite intermittent clerical complaint. In practice, the limitations on ecclesiastical jurisdiction—notably, the attempted exclusion of pleas of debt from church courts—were not definitive.

An English translation of the text is in D. C. Douglas and G. W. Greenaway (eds.), *English Historical Documents, 1042–1189* (London, New York, 1953). (ER. S.)

CLARES, POOR, otherwise CLARISSES, Franciscan nuns, so called from their foundress, St. Clara (*q.v.*). She was professed by St. Francis in the Portiuncula in 1212, and two years later she and her first companions were established in the convent of St. Damian at Assisi. The nuns formed the "Second Order of St. Francis," the friars being the "First Order" and the Tertiaries (*q.v.*) the "Third."

Before Clara's death in 1253, the Second Order had spread all over Italy and into Spain, France and Germany; in England they were introduced about 1293 and established in London, outside Aldgate, where their name of Minoresses survives in the Minories; there were only two other English houses before the dissolution.

St. Francis gave the nuns no rule, but only a "Form of Life" and a "Last Will," each only five lines long and coming to no more than an inculcation of his idea of evangelical poverty. Something more than this became necessary as soon as the institute began to spread; and during Francis's absence in the east, 1219, his supporter Cardinal Hugolino composed a rule which made the Franciscan nuns practically a species of unduly strict Benedictines, St. Francis's special characteristics being eliminated. St. Clara made it her life work to have this rule altered and to get the Franciscan character of the Second Order restored; in 1247 a "Second Rule" was approved which went a long way toward satisfying her desires, and finally in 1253 a "Third," which practically gave what she wanted. This rule has come to be known as the "Rule of the Clares"; it is one of great poverty, seclusion and austerity of life. Most of the convents adopted it, but several clung to that of 1247. To bring about conformity St. Bonaventura, while general (1264), obtained papal permission to modify the rule of 1253, somewhat mitigating its austerities and allowing the convents to have fixed incomes. This rule was adopted in many convents, but many more adhered to the strict rule of 1253. Indeed a countertendency toward a greater strictness set in, and a number of reforms were initiated, introducing an appalling austerity of life.

See Heimbucher, *Orden und Kongregationen* (1896), i. §§ 47, 48, who gives references to all the literature; and *Catholic Encyclopaedia*, art. "Clares."

CLARET is the type-name popularly applied to any dry, tart, light- or medium-bodied table wine of ruby red colour. Wines of this general type are the most widely-used mealtime wines in almost every wine-growing country. They range from high-quality wines, produced under ideal conditions from grapes of the noblest character, to very humble *vins ordinaires*, as common wines are called in France. They may rise to the challenge of many years of aging, improving all the while, or they may be at their best when fairly young.

The name originated with the English, to whom in the 12th century claret meant simply a red wine of lighter colour than the very dark wines of southern Europe. In the 12th and 13th centuries red and white wines were sometimes blended to produce claret. Gradually, however, the term came to be applied to the red wines of the Bordeaux vineyards, which were lighter in colour than those of the higher country toward the Pyrenees. When in 1152 the marriage of Henry of Anjou (later Henry II) and Eleanor of Aquitaine brought the whole of Aquitaine under English sovereignty, the merchants of Bordeaux acquired the rights of crown subjects; they used their privileges in London to promote the wine trade from Bordeaux at the expense of that from Rouen and elsewhere. Eventually an export tax was levied on wines at Bordeaux for the benefit of the king's house, and for this reason the English were encouraged to consume Bordeaux wines. Inasmuch as English rule over Aquitaine lasted three centuries, the use of Bordeaux red wines, or clarets, became firmly fixed. Claret is far now from the meaning of the French word "clairette," which refers to a white wine faintly tinged with red.

The greatest clarets of the Bordeaux region come, as a rule, from the two viticultural districts of Médoc and Graves, which lie along the left banks of the Gironde and the Garonne, respectively. There the best vineyards regularly yield wines capable of improving with age and in good years distinguished for their bouquet and balance. Even in these districts, however, there are many grades of clarets, ranging down through five official classes of better growths, or *crûs*, as determined by a jury in 1855, to such commoner ones as "bourgeois," "artisan" and "peasant."

Because in this region growing conditions vary widely from year to year, vintage years matter greatly to the producers of Bordeaux wines. Some of the most noted red wines grown in a favourable year in Médoc or Graves do not mature sufficiently to please the palate until they have aged ten years, and may improve steadily thereafter for a couple of decades or more. But even the most notable of them, grown in a poor year, may pass their zenith before they are seven. And many lesser wines, even in the good years, are sold to be drunk with meals much earlier.

The Cabernet Sauvignon, whose sweet, violet-odoured fruit grows in small, loose bunches, is the chief vine grown in the Bordeaux region to produce great clarets. However, nearly all vineyards have other grape varieties for claret, including the Carmenère, Gros-Cabernet, Malbec, Merlot and Petit Verdot.

Italy, Spain, Portugal and other countries of Europe have developed their own styles of claret, often from grapes nurtured through centuries on their own soils. In the newer lands, including the Americas, Australia and South Africa, adaptable grape varieties transplanted from those countries as well as from the Gironde are used. Thus in California the Cabernet Sauvignon is favoured in those parts where it can be grown under ideal conditions but some other varieties are more widely employed, including the more productive Zinfandel, probably of Hungarian origin, which produces a fresh, fruity wine not usually given to long aging. (*See* WINE.) (H. A. CW.)

CLARETIE, JULES ARSÈNE ARNAUD (1840–1913), French writer, director of the Théâtre Français, was born at Limoges Dec. 3, 1840. He was dramatic critic to the *Figaro* and to the *Opinion nationale*, a newspaper correspondent during the Franco-German War, and during the Commune a staff-officer in the National Guard. In 1885 he became director of the Théâtre Français, and from that time devoted himself chiefly to its administration. He was elected a member of the Academy in 1888. He died in Paris on Dec. 23, 1913.

The long list of his works includes *Histoire de la révolution de 1870–71* (new ed., 5 vols., 1875–76); *Cinq ans après; l'Alsace et la Lorraine depuis l'annexion* (1876); some annual volumes of reprints of his articles in the weekly press, entitled *La Vie à Paris; La Vie moderne au théâtre* (1868–69); *Molière, sa vie et son oeuvre* (1871); *Histoire de la littérature française, 900–1900* (2nd ed. 1905); *Candidat!* (1887), a novel of contemporary life; *Brichanteau, comédien français* (1896); several plays, some of which are based on novels of his own; and the opera, *La Navarraise* based on his novel *La Cigarette*, and written with Henri Cain to the music of Massenet. *La Navarraise* was first produced at Covent Garden (June 1894) with Mme. Calvé in the part of Anita. His *Oeuvres complètes* were published in 1897–1904. *See* G. Grappe, *Jules Claretie* (1906).

CLARI, GIOVANNI CARLO MARIA (*c.* 1669–1745), Italian composer, born at Pisa, was the most celebrated pupil of Colonna, chapelmaster of S. Petronio, at Bologna. He became *maestro di cappella* at Pistoia, at Bologna and at Pisa. The works by which Clari distinguished himself are his vocal duets and trios with a *basso continuo*, published between 1740 and 1747. These compositions, which combine graceful melody with contrapuntal learning, were much admired by Luigi Cherubini and also by George Frederick Handel, who borrowed material from portions of them.

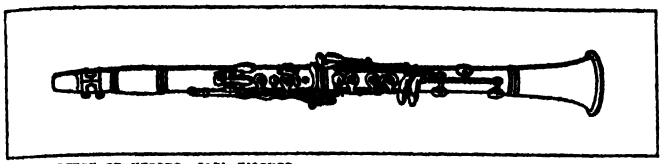
Clari composed one opera, *Il Savio delirante*, produced at Bologna in 1695, and a large quantity of church music, several specimens of which have been printed in Vincent Novello's *Fitzwilliam Music*.

CLARINA, a modern instrument of the wood-wind class (although actually made of metal), a hybrid possessing characteristics of both oboe and clarinet. The clarina was invented by W. Heckel of Biebrich-am-Rhein, and has been used at Bayreuth, in *Tristan und Isolde*, as a substitute for the *Holztrompete* made according to Richard Wagner's instructions.

CLARINDA, county seat of Page county, Ia., U.S., on the Nodaway river, federal highway 71, state highway 2 and the Burlington railway. The population in the 1950 federal census was 5,077 (4,962 in 1930; 4,905 in 1940). The chief industries are coal mining, agriculture and manufacturing.

A state hospital for the mentally unbalanced, with a capacity for 1,500 patients, is located there. Clarinda was settled about 1853 and incorporated in 1866.

CLARINET, a wood-wind instrument having a cylindrical bore and played by means of a single-reed mouthpiece. The name is sometimes used in a generic sense to denote the whole family, which consists of the ordinary clarinet, corresponding to the violin, oboe, etc.; the alto clarinet in E; the basset horn (*q.v.*) in F; the bass clarinet (*q.v.*), and the pedal clarinet (*q.v.*).



The mouthpiece of the clarinet, including the beating or single-reed common to the whole clarinet family, has the appearance of a beak with the point bevelled off and thinned at the edge to correspond with the end of the reed shaped like a spatula. The under part of the mouthpiece is flattened in order to form a table for the support of the reed, which is adjusted thereon with great nicety, allowing just the amount of play requisite to set in vibration the column of air within the tube.

A cylindrical tube played by means of a reed has the acoustic properties of a stopped pipe, *i.e.*, the fundamental tone produced by the tube is an octave lower than the corresponding tone of an open pipe of the same length, and overblows a twelfth; whereas tubes having a conical bore like the oboe, and played by means of a reed, speak as open pipes and overblow an octave. This forms the fundamental difference between the instruments of the oboe and clarinet families.

Wind instruments depending upon lateral holes for the production of their scale must either have as many holes pierced in

the bore as they require notes, or make use of the property possessed by the air-column of dividing into harmonics or partials of the fundamental tones. Twenty to twenty-two holes is the number generally accepted as the practical limit for the clarinet. The compass of the instrument is therefore extended through the medium of the harmonic overtones.

In order to facilitate, however, the production of the harmonic notes, a small hole, closed by means of a key and called the "speaker," is bored near the mouthpiece. By means of this small hole the air-column is placed in communication with the external

BY COURTESY OF MESSRS. CARL FISCHER

THE CLARINET, A MUSICAL INSTRUMENT WITH A SINGLE BEATING REED, DERIVED FROM THE CHALUMEAU OF THE MIDDLE AGES

atmosphere, a ventral segment is formed, and the air-column divides into three equal parts, producing a triple number of vibrations resulting in the third note of the harmonic series, at an interval of a twelfth above the fundamental.

The fundamental scale of the modern clarinet in C extends from E in the bass clef to B flat in the treble. The next octave and a half is obtained by opening the speaker key, whereby each of the fundamental notes is reproduced a twelfth higher, extending the range to F in alt, which ends the natural compass of the instrument, although a skilful performer may obtain another octave by cross-fingering.

History.—The single beating-reed associated with the instruments of the clarinet family was probably introduced into classic Greece from Egypt or Asia Minor. A few ancient Greek instruments are extant, five of which are in the British Museum. They are as nearly cylindrical as would be the natural growing reed itself. The probability is that both single and double reeds were at times used with the Greek aulos and the Roman tibia.

In the West, the instrument was, during the Carolingian period, identified with the tibia of the Romans until such time as the new western civilization ceased to be content to go back to classical Rome for its models, and began to express itself, at first naïvely and awkwardly, as the 11th century dawned. The name then changed to the derivatives of the Greek *kalamos*, assuming an almost bewildering variety of forms, of which the commonest are chalcame, chalumeau, schalmey, scalmeye, shawm, calemel.

At the beginning of the 18th century various important improvements in the mechanism of the instrument, in particular the invention of the very useful device of the speaker-key, were effected by J. Christian Denner (1655–1707), and after various subsequent developments the instrument was further improved during the 19th century by the Belgian makers Bachmann, the elder Sax, Albert and C. Mahillon and others. In England the clarinet has also passed through several progressive stages since its introduction about 1770, first at the hands of Cornelius Ward, and later, as a consequence of still more important improvements due to Richard Carte and others.

As regards music for the clarinet, Mattheson mentions clarinet music in 1713, although Handel, whose rival he was, does not appear to have known the instrument. Joh. Christ. Bach scored for the clarinet in 1763 in his opera *Orione*, performed in London, and Rameau had already employed the instrument in 1751 in a theatre for his pastoral entitled *Acante et Céphise*. Later, Mozart wrote for it in his Paris symphony, and since then it has of course long since taken its place as one of the most indispensable members of the orchestral family. Famous chamber works in which the instrument is employed are the clarinet quintets of Mozart and Brahms.

CLARK, ABRAHAM (1726–1794), American patriot and signer of the Declaration of Independence, was born in Elizabethtown, N.J., on Feb. 15, 1726. After receiving his education in mathematics and civil law, he engaged in conveyancing and surveying. Though he did not enter the professional practice of law, he gave legal advice gratuitously to his neighbours, earning the title, "the poor man's counsellor." He served as clerk of the New Jersey colonial assembly, and later was appointed high sheriff of Essex county. As an active Whig, he served on the committees of vigilance and public safety in his native State, and in June 1776 was appointed a representative to the general Congress, where he voted for separation from England and signed the Declaration of Independence. Eight times in the following 12 years he was elected a member of that body, and he was chosen a delegate to the Constitutional Convention in Philadelphia in 1787, but illness prevented his attendance. In Congress, on Wednesday, July 2, 1788, he made the motion by which the Federal Constitution became effective. The State legislature appointed him, in the winter of 1789–90, a commissioner to settle debts of New Jersey contracted during the Revolution, which duties he discharged until elected a member of the second Congress. This office he held until June 1794. He died at Elizabethtown, N.J., on Sept. 15, 1794.

See A. C. Hart, ed., *Abraham Clark* (San Francisco, 1923).

CLARK, CHAMP (1850–1921), American politician, was born in Anderson Co., Ky., on March 7, 1850. He first entered Kentucky university but finished his course at Bethany college in 1873. The following year he was elected president of Marshall college, West Virginia, and one year later was admitted to the bar. After 1880 his law office was in Bowling Green, Missouri. He was city attorney for Louisiana, Mo., and for Bowling Green from 1878 to 1881; and was prosecuting attorney for Pike Co., 1885–89, and then for three years was a member of the Missouri house of representatives. He was a member of congress from 1893 to 1895, and from 1897 to 1919, being speaker from 1911 to 1919. At the Democratic convention for the nomination of a presidential candidate held at Baltimore in 1912, he led on 27 ballots and on 8 had a clear majority, but not the necessary two-thirds. He was finally defeated by Woodrow Wilson of New Jersey. He died in Washington, D.C., on March 2, 1921.

CLARK, FRANCIS EDWARD (1851–1927), American clergyman, was born of New England ancestry at Aylmer, Province of Quebec, Canada, Sept. 12, 1851. He graduated at Dartmouth college in 1873 and at Andover theological seminary in 1876, and was pastor successively of the Williston Congregational church in Portland, Me., and of the Phillips Congregational church in South Boston, Mass. In Feb. 1881 he founded at Portland the Young People's Society of Christian Endeavour, which beginning as a small society in a single New England church, developed into a great interdenominational organization, which reported 80,000 societies and more than 4,000,000 members throughout the world. For many years he devoted himself to this work as president and finally president emeritus of the United Societies of Christian Endeavour and president of the World's Christian Endeavour Union, and as editor, and then honorary editor of the *Christian Endeavor World* until his death at Newton, Mass., on May 26, 1927.

Among his publications are *Looking Out on Life* (1883); *World Wide Endeavor* (1895); *Christian Endeavor Manual* (1903); and *Christian Endeavor in All Lands* (1906). *The Continent of Opportunity* (1909); *Old Home of New Americans* (1912); *The Holy Land of Asia Minor* (1914); *The Charm of Scandinavia* (with Sydney A. Clark) (1914); *Christ and the Young People* (1916); *In the Footsteps of St. Paul* (1917); *The Gospel of Out-of-Doors* (1920); *Memories of Many Men in Many Lands* (1923).

CLARK, GEORGE ROGERS (1752–1818), American frontier military leader, was born in Albemarle county, Virginia, on Nov. 19, 1752. When 19 years of age he left his home to become a surveyor of frontier lands along the Ohio river. This occupation was soon interrupted by an Indian outbreak known as Lord Dunmore's War (1774); and Clark, with the rank of captain, accompanied Dunmore in the punitive expedition. Peace brought renewed immigration, especially into Kentucky, and thither Clark followed as a surveyor for the Ohio company. His position enabled him from time to time to absorb choice portions of land for himself, and these interests soon led him to identify himself with the Kentuckians and devote much thought to their peculiar problems. When the American Revolution broke out Clark clearly perceived the vulnerability of the frontier, and the necessity of securing for Kentucky a government with military

authority and an organized militia if there was to be concerted defense against the British, or their allies, the Indians. Elected by a mass meeting of the pioneers to present their problems before the Virginia government, Clark attended the council and assembly at Williamsburg and diplomatically persuaded them to create a separate county of Kentucky and thereby become responsible for its defense. Clark returned with a supply of powder and assumed chief command of the frontier militia at a critical moment, for the Indians were already making raids against the settlers. Convinced that they were instigated and supported in their raids by British officers stationed in the forts north of the Ohio river, Clark worked out a plan of offensive operations that involved nothing less than a conquest of these forts. His plans were approved by Governor Patrick Henry and the council of Virginia and Clark was authorized to enlist troops. May 1778 found him at the falls of the Ohio with about 175 men. The expedition proceeded to Ft. Kaskaskia, on the Mississippi river, in what is now Illinois. This place and Cahokia, also on the Mississippi, near St. Louis, were defended by small British garrisons, which depended on the support of the French inhabitants. The French being willing to accept the authority of Virginia, both forts were easily taken. Clark gained the friendship of Father Gibault, the priest at Kaskaskia, and through his influence the French at Vincennes on the Wabash were induced to change their allegiance. Lieut. Governor Hamilton, the British commander at Detroit, recovered Vincennes, however, and went into winter quarters there. After an arduous march across flooded bottom land in freezing weather, Clark in Feb. 1779, surprised Hamilton and forced him to give up Vincennes, and surrender himself and his garrison as prisoners of war. The way was now open to Detroit, Clark's ultimate object, but it was deemed prudent to wait for reinforcements promised from Virginia in June. The delay was fatal; other occurrences delayed the reinforcements and scattered Clark's troops. Clark withdrew to Ft. Nelson which he had built at the falls of the Ohio, and made that his base for the rest of the war. In 1780 he aided in the defeat of a British expedition against the Spanish settlement of St. Louis; the same year he made a swift campaign against the Shawnee Indians and destroyed their towns, Chillicothe and Piqua. Clark, now appointed brigadier general of the western forces, again planned to move against Detroit and was promised supplies and reinforcements for the expedition from Virginia. Months went by and they did not come, for Virginia was bankrupt. Again in 1782 Clark took the offensive against the Shawnees, and while not entirely successful this last expedition saved the settlements from renewed Indian attacks and defeated British plans for an Indian alliance. When peace came in 1783 (treaty of Paris) Clark's conquests doubtless influenced the award of the country northwest of the Ohio to the United States. His offensive movements had also been of first importance in defending the vulnerable frontier from Indian raids and British expeditions. Clark and his men during all these years received no pay for their services and hardships. Furthermore Clark found himself responsible for all debts incurred for supplies, since Virginia, despite her promises, never reimbursed him. The rest of his life was shadowed by the constant demands of creditors. Clark was appointed an Indian commissioner after the war, and in 1786 he played a leading part in a treaty with the Shawnees. The same year he led an expedition against the "Wabash confederacy," his last military command. James Wilkenson, a traitor in the pay of Spain (unknown at that time), coveted Clark's office of Indian commissioner and his military command, and deliberately set out to misrepresent him. Forged papers and testimonials were forwarded to Governor Randolph of Virginia charging Clark with constant drunkenness, military incapacity, and a treasonable design of leading a military expedition down the Mississippi against Spain. Wilkenson was entirely successful; he was appointed Indian commissioner in Clark's place, and the latter was relieved of his command. Disappointed at his country's ingratitude, Clark spent the rest of his life near Louisville in retirement, dying on Feb. 13, 1818. Historical research in recent years has exposed Wilkenson's perfidy, and emphasized the importance of Clark's exploits. His most ardent supporters have even called him "the Washington of the West."

BIBLIOGRAPHY.—The *George Rogers Clark Papers, 1771–1783*, ed. J. A. James, are contained in vol. viii and ix of the *Illinois Historical Collections* (Springfield, 1912 and 1926). Clark's own narrative of his campaigns is published in *The Captive of Old Vincennes* (Indianapolis, 1927), ed. M. M. Quaife. The best biography is Temple Bodley's *George Rogers Clark: His Life and Public Services* (Boston, 1926). *See* also W. H. English, *Conquest of the Country North-west of the River Ohio, 1778–1783* (1896), and the *Mississippi Valley Historical Review* for Sept. 1924; Frederick Palmer, *Clark of the Ohio: A Life of George Rogers Clark* (1929).

CLARK, JOHN BATES (1847–1938), often called the dean of American economists, was born in Providence, R.I., Jan. 26, 1847. He was educated at Brown university, Amherst college, Heidelberg and Zurich, and became imbued with the ideas of the German historical school. Returning to America, he taught at Carlton, Smith and Amherst colleges, and finally at Columbia university (1895–1923). The first period of his economic thought, influenced by the historical school, culminated in *The Philosophy of Wealth* (1885). In "revolt," as he said, "against the spirit of the old political economy," he rejected competition as the rule of distributive justice. Nevertheless, he outlined independently an "effective utility" theory of competitive value resembling that of Jevons and the Austrian school somewhat earlier.

A second period culminated in 1899 in his chief work, *The Distribution of Wealth*, marked by the rejection of the old categories of production factors, but ultra "classical" in accepting competitive price (which he called the "specific productivity" of agents) as the just rule of distribution. Despite some contemporary protests, Clark's views dominated economic theorizing in the United States for a generation, and left lasting effects in clearer conceptions of a "universal law of economic variation," of a price "system," and of the categories of productive agents.

Clark's later work is noteworthy for his original and practicable proposals for the correction of monopolistic abuses, presented in final form in *The Control of Trusts* (1912), but not yet fully realized in public policy. (F. A. F.)

CLARK, JOSIAH LATIMER (1822–1898), English engineer and electrician, was born on March 10, 1822, at Great Marlow, Bucks. In 1848 he became assistant engineer at the Menai Straits bridge under his elder brother Edwin (1814–94), the inventor of the Clark hydraulic lift graving dock. Two years later, when his brother was appointed engineer to the Electric Telegraph company, he again acted as his assistant, and subsequently succeeded him as chief engineer. In 1854 he took out a patent "for conveying letters or parcels between places by the pressure of air and vacuum," and later was concerned in the construction of a large pneumatic despatch tube between the general post office and Euston station, London. He also experimented on the propagation of the electric current in submarine cables, and in 1859 he was a member of the committee which was appointed by the government to consider the numerous failures of submarine cable enterprises. Latimer Clark paid much attention to the subject of electrical measurement, and besides designing various improvements in method and apparatus and inventing the Clark standard cell, he took a leading part in the movement for the systematization of electrical standards, which was inaugurated by the paper which he and Sir C. T. Bright read on the question before the British association in 1861. With Bright also he devised improvements in the insulation of submarine cables. He was a member of several firms engaged in laying submarine cables, in manufacturing electrical appliances, and in hydraulic engineering. He died in London on Oct. 30, 1898.

Clark's chief works are: *Electrical Measurement* (1868); and, with R. Sabine, *Electrical Tables and Formulae for Operators in Submarine Cables* (1871).

CLARK, THOMAS (1801–1867), Scottish chemist, was born at Ayr on March 31, 1801, and died at Glasgow on Nov. 27, 1867. He was professor of chemistry at Marischal college, Aberdeen, and is best known for his process for softening hard waters and his water tests, patented in 1841.

CLARK, WILLIAM (1770–1838), American soldier and explorer, the youngest brother of George Rogers Clark, was born

in Caroline county, Va., but early removed to Kentucky. He entered the U.S. army as lieutenant of infantry in 1792, and served under Gen. Anthony Wayne against the Indians in 1794. In 1803–06, with Meriwether Lewis, he commanded the famous exploring expedition from St. Louis to the mouth of the Columbia river and return, the first expedition to cross the continent within the limits of the United States. He was territorial governor of Missouri from 1813 to 1820, and superintendent of Indian affairs at St. Louis from 1822 until his death in 1838.

See the *Original Journals of the Lewis and Clark Expedition* (1905), edited by R. G. Thwaites, the best of several editions of the leader's journals; George Bird Grinnell, *Trails of the Pathfinders* (1911); "William Clark's Journal of General Wayne's Campaign, 1793–1794," *Mississippi Valley Hist. Rev.*, vol. i. p. 413–443 (Cedar Rapids, Iowa, 1914); and Floyd Duckworth Welch, *The Work of the Indian Agents in the Louisiana Purchase, 1804–1820* (St. Louis, Mo., 1926).

CLARK, WILLIAM GEORGE (1821–1878), English classical and Shakespearian scholar, was born at Barford Hall, Darlington, in March 1821 and died at York on Nov. 6, 1878. In 1853 Clark had taken orders, but left the church in 1870 after the passing of the Clerical Disabilities Act, of which he was one of the promoters. He established the Cambridge *Journal of Philology*, and co-operated with B. H. Kennedy and James Riddell in the production of the well-known *Sabrinae Corolla*. The work by which he is best known is the Cambridge Shakespeare (1863–66), containing a collation of early editions and selected emendations, edited by him at first with John Glover and afterwards with W. Aldis Wright. *Gazpacho* (1853) gives an account of his tour in Spain; his visits to Italy at the time of Garibaldi's insurrection, and to Poland during the insurrection of 1863, are described in *Vacation Tourists*, ed. F. Galton, i. and iii.

See H. A. J. Munro in *Journal of Philology* (viii., 1879); also notices by W. Aldis Wright in *Academy* (Nov. 23, 1878); R. Burn in *Athenaeum* (Nov. 16, 1878); *The Times* (Nov. 8, 1878); *Notes and Queries*, 5th series, x. (1878), p. 400.

CLARKE, ADAM (1762?–1832), British Nonconformist divine, was born at Moybeg, Co. Londonderry, Ireland, in 1760 or 1762. He completed his education at Kingswood school and in 1782 was appointed by Wesley minister to the Bradford (Wiltshire) circuit. He was a great preacher, and was three times (1806, 1814, 1822) chosen to be president of the conference. He served twice on the London circuit, the second period being extended considerably longer than the rule allowed, at the special request of the British and Foreign Bible Society, who had employed him in the preparation of their Arabic Bible. He found time in his busy life to study Hebrew and other Oriental languages, in order to qualify himself for the great work of his life, his *Commentary on the Holy Scriptures* (1810–26). In 1802 he published a *Bibliographical Dictionary* in six volumes, to which he afterwards added a supplement. He was selected by the Records Commission to re-edit Rymer's *Foedera*, a task which after ten years' labour (1808–18) he had to resign. He also wrote *Memoirs of the Wesley Family* (1823), and edited a large number of religious works. He died in London on Aug. 16, 1832.

His *Miscellaneous Works* were published in 1836, and a *Life*, by his son J. B. B. Clarke, appeared in 1833.

CLARKE, ALEXANDER ROSS (1828–1914), British geodesist, was born in Sutherlandshire on Dec. 16, 1828. He studied at the Royal Military academy, Woolwich, and in 1847 became a second-lieutenant in the Royal Engineers. In 1850 Clarke was posted to the Ordnance Survey at Southampton, and except for a break between 1851–54 he remained there until he retired in 1881.

When Clarke joined the Ordnance Survey the observations on the Principal Triangulation had just been completed, and he had the task of reducing and publishing the results. This was done in record time, and in 1858 appeared *Account of the Observations and Calculations of the Figure, Dimensions and Mean Specific Gravity of the Earth as Derived Therefrom*. Clarke was mainly responsible for a good deal of similar work carried out in co-operation with other countries. His work was remarkably accurate and rapid, considering the laborious methods of calculation and reduction in use at the time. In a specially-designed room he tested and compared the standards of length used by other countries and by the Colonies, publishing his observations in *Comparison of the Standards of Length of England, France, Belgium, Prussia, India and Australia* (1866).

Clarke gave an account of the observations which connected the English and French triangulations under the title of *Extension of the Triangulation of Great Britain into France and Belgium* (1863). He was the author of *Abstracts of Spirit Levelling in England, Wales and Scotland* (1861), *Geodesy* (1880), a standard work on this subject, which has been translated into many languages, and a number of papers in scientific journals. He was a member of many learned societies and was awarded the Royal Medal of the Royal Society in 1887. He had been made a Companion of the Bath in 1870. In 1881 Clarke was ordered to hold himself ready for service in Mauritius and preferred to retire rather than sever his connection with the Ordnance Survey. He lived a secluded life until he died on Feb. 11, 1914.

CLARKE, SIR ANDREW (1824–1902), British soldier and administrator, son of Col. Andrew Clarke, of Co. Donegal, Ireland, governor of West Australia, was born at Southsea, England, on July 27, 1824, and educated at King's school, Canterbury. He entered the army in 1844 as second-lieutenant in the Royal Engineers. He was appointed to his father's staff in West Australia, but was transferred to be A.D.C. and military secretary to the governor of Tasmania; and in 1847 he went to New Zealand to take part in the Maori War, and for some years served on Sir George Grey's staff. He was then made surveyor-general in Victoria, took a prominent part in framing its new constitution, and held the office of minister of public lands during the first administration (1855–57). From 1864–73 he was director of works for the navy, being responsible for great improvements in the naval arsenals and fortifications at home and abroad. In 1873 he became governor of the Straits Settlements. From 1875–80 he was minister of public works in India; and on his return to England in 1881, he was first appointed commandant at Chatham and then inspector-general of fortifications (1882–86). He died on March 29, 1902. Both as a technical and strategical engineer and as an Imperial administrator Sir Andrew Clarke was one of the ablest and most useful public servants of his time.

CLARKE, SIR CASPAR PURDON (1846–1911), English art expert, was born in London on Dec. 21, 1846, and educated privately at Sydenham and Boulogne. In 1862 he was trained as an architect in the art schools at South Kensington. In 1865 he entered the Office of Works, and in 1867 was attached to the works department of the South Kensington museum. He travelled extensively for the museum, purchasing objects of art, and at the same time carried on his profession as an architect. In 1883 he became keeper of the India museum at South Kensington, in 1892 keeper of the art collections, in 1893 assistant-director, and in 1896 director. In 1905 he became director of the Metropolitan Museum, New York, resigning in 1910. He was knighted in 1902. He died in London on March 29, 1911.

CLARKE, CHARLES COWDEN (1787–1877), English author and Shakespearian scholar, was born at Enfield, Middlesex, on Dec. 15, 1787. His father, John Clarke, was a schoolmaster, among whose pupils was John Keats. Charles Clarke taught Keats his letters, and encouraged his love of poetry. He knew Charles and Mary Lamb, and afterwards became acquainted with Shelley, Leigh Hunt, Coleridge and Hazlitt. Clarke became a music publisher in partnership with Alfred Novello, and married in 1828 his partner's sister, Mary Victoria (1809–98), the eldest daughter of Vincent Novello. In the year after her marriage Mrs. Cowden Clarke began her valuable Shakespeare concordance, which was eventually issued in 18 monthly parts (1844–45), and in volume form in 1845 as *The Complete Concordance to Shakespeare, being a Verbal Index to all the Passages in the Dramatic Works of the Poet*. This work superseded the *Copious Index to . . . Shakespeare* (1790) of Samuel Ayscough, and the *Complete Verbal Index . . .* (1805–07) of Francis Twiss. Charles Cowden Clarke published many useful books, and edited the text for John Nichol's edition of the British poets; but his most important

work consisted of lectures delivered between 1834 and 1856 on Shakespeare and other literary subjects. Some of the more notable series were published, among them being *Shakespeare's Characters, chiefly those subordinate* (1863), and *Molière's Characters* (1865). In 1859 he published a volume of original poems, *Carmina Minima*. For some years after their marriage the Cowden Clarkes lived with the Novellos in London. In 1849 Vincent Novello with his wife removed to Nice, where he was joined by the Clarkes in 1856. After his death they lived at Genoa at the Villa Novello. They collaborated in *The Shakespeare Key, unlocking the Treasures of his Style . . .* (1879), and in an edition of Shakespeare for Messrs. Cassell, which was issued in weekly parts, and completed in 1868. It was reissued in 1886 as *Cassell's Illustrated Shakespeare*. Charles Clarke died on March 13, 1877, at Genoa, and his wife survived him until Jan. 12, 1898. Among Mrs. Cowden Clarke's other works may be mentioned *The Girlhood of Shakespeare's Heroines* (1850–52), and a translation of Berlioz's *Treatise upon Modern Instrumentation and Orchestration* (1856).

See *Recollections of Writers* (1898), a joint work by the Clarkes containing letters and reminiscences of their many literary friends; and Mary Cowden Clarke's autobiography, *My Long Life* (1896). A charming series of letters (1850–61), addressed by her to an American admirer of her work, Robert Balmanno, was edited by Anne Upton Nettleton as *Letters to an Enthusiast* (Chicago, 1902).

CLARKE, EDWARD DANIEL (1769–1822), English mineralogist and traveller, was born at Willingdon, Sussex, on June 5, 1769, and educated at Tonbridge and Jesus college, Cambridge. In 1799–1803 he made an extended tour through the continent of Europe and afterwards to Egypt and Palestine. After the capitulation of Alexandria, Clarke was of considerable use in securing for England the statues, sarcophagi, maps, manuscripts, etc., which had been collected by the French savants. He returned home by way of Athens, Constantinople, Rumelia, Austria, Germany and France. On arriving in England Clarke made important donations to Cambridge university, including a colossal statue of the Eleusinian Ceres. He received the livings of Harlton and Yeldham and near the end of 1808 was appointed to the professorship of mineralogy in Cambridge, then first instituted. The mss. which he had collected in the course of his travels were sold to the Bodleian library. He was also appointed university librarian in 1817 and was one of the founders of the Cambridge Philosophical Society in 1819. He died in London on March 9, 1822.

The following is a list of his principal works: *Testimony of Authors respecting the Colossal Statue of Ceres in the Public Library, Cambridge* (1801–3); *The Tomb of Alexander, a Dissertation on the Sarcophagus brought from Alexandria, and now in the British Museum* (1805); *A Methodical Distribution of the Mineral Kingdom* (Lewes, 1807); *A Description of the Greek Marbles brought from the Shores of the Euxine Archipelago and Mediterranean and deposited in the University Library, Cambridge* (1809); *Travels in Various Countries of Europe, Asia and Africa* (1810–19; 2nd ed., 1811–23).

See Rev. W. Otter, *Life and Remains of E. D. Clarke* (London, 1824).

CLARKE, SIR EDWARD GEORGE (1841–1931), English lawyer and politician, son of J. G. Clarke, of Moorgate street, London, was born on Feb. 15, 1841. In 1859 he became a writer in the India office, but resigned in the next year, and became a law reporter. He obtained a Tancred law scholarship in 1861, and was called to the bar at Lincoln's Inn in 1864. He joined the home circuit, became Q.C. 1880, and a bencher of Lincoln's Inn in 1882. He appeared, among other cases, as counsel for Patrick Staunton in the Penge murder case (1877) for Mrs. Bartlett (1886), for Sir W. Gordon-Cumming in his slander action (in which Edward VII., then Prince of Wales, gave evidence), and for Dr. Jameson in 1896. He was knighted in 1886. He was returned as Conservative member for Southwark at a by-election early in 1880, but failed to retain his seat at the general election which followed a month or two later; he found a seat at Plymouth, however, which he retained until 1900. He was solicitor-general in the Conservative administration of 1886–92, but declined office under the Unionist government of 1895 when the law officers of the crown were debarred from private practice. The most remarkable, perhaps, of his speeches in the House of Commons was his reply to Mr. Gladstone on the second reading of the Home Rule Bill in 1893. In 1899 he resigned his seat on the question of the government's South African policy. At the general election in 1906 he was returned at the head of the poll for the city of London, but he offended a large section of his constituents by a speech against tariff reform in the House of Commons on March 12, and shortly afterwards he resigned his seat on grounds of health. He retired from the bar in 1914 and died in 1931.

He published a *Treatise on the Law of Extradition* (4th ed. 1903), four volumes of his political and forensic speeches; *The New Testament: The Authorised Version Corrected* (1913); *The Book of Psalms: the Prayer Book Version Corrected* (1915); and his autobiography, *The Story of My Life* (1918).

CLARKE, JAMES FREEMAN (1810–1888), American preacher and author, was born in Hanover (N.H.) on April 4, 1810. He graduated at Harvard college in 1829, and at the Harvard divinity school in 1833. He was then ordained as minister of a Unitarian congregation at Louisville (Ky.), and soon threw himself heart and soul into the national movement for the abolition of slavery, though he was never a "radical abolitionist." In 1839 he returned to Boston, where he and his friends established (1841) the "Church of the Disciples," which brought together a body of men and women active and eager in applying the Christian religion to the social problems of the day. Of this church he was the minister from 1841–50 and from 1854 until his death. He was also secretary of the Unitarian Association and in 1867–71 professor of natural religion and Christian doctrine at Harvard. From 1836–39 he was editor of the *Western Messenger*, a magazine which is now of value to collectors because it contains the earliest printed poems of Ralph Waldo Emerson, who was Clarke's personal friend. Most of Clarke's earlier published writings were addressed to the immediate need of establishing a larger theory of religion than that espoused by people who were still trying to be Calvinists, people who maintained what a good American phrase calls "hard-shelled churches." But it would be wrong to call his work controversial. In the great moral questions of his time he was a fearless and practical advocate of the broadest statement of human rights. He published but few verses, but at the bottom he was a poet. He was a diligent and accurate scholar, and among the books by which he is best known is one called *Ten Great Religions* (2 vols., 1871–83). Few Americans have done more than Clarke to give breadth to the published discussion of the subjects of literature, ethics and religious philosophy. Among his books are *Orthodoxy* (1866); *Every-Day Religion* (1886) and *Sermons on the Lord's Prayer* (1888). He died at Jamaica Plain (Mass.) on June 8, 1888.

His *Autobiography, Diary and Correspondence*, edited by Edward Everett Hale, was published in 1891. (E. E. H.)

CLARKE, JOHN MASON (1857–1925), U.S. palaeontologist and geologist, was born at Canandaigua, N.Y., on April 15, 1857. He was educated at the Canandaigua academy, Amherst college and the University of Göttingen, Germany. On Jan. 1, 1886, after several years of teaching, he became assistant to James Hall, whom he succeeded as state palaeontologist of New York in 1898. In 1904 he became both state geologist and palaeontologist and director of the state museum. Under his direction it became the foremost museum of its type in the United States, with extensive and novel exhibits, publications and research programs in geology, palaeontology, archaeology and several branches of biology.

Clarke began to collect Devonian fossils at the age of six, and became the foremost U.S. authority on that geologic system. His studies embraced brachiopods, crustaceans and glass sponges, as well as Devonian faunas of North and South America and Germany, and Devonian formations and history of eastern United States and Canada. He also described some Silurian faunas, and with Rudolf Ruedemann was author of a two-volume work on the eurypterids, or sea scorpions. Clarke died in Albany, N.Y., May 29, 1925. A bibliography of his 380 publications appears in the *Bulletin of the Geological Society of America*, vol. 37, no. 1, pp. 49–93 (1926). (M. A. F.; C. L. Fe.)

CLARKE, MARCUS ANDREW HISLOP (1846–1881), Australian author, was born in London on April 24, 1846, and died at Melbourne on Aug. 2, 1881. He emigrated about 1863 to Australia, where his uncle, James Langton Clarke, was a county

court judge. He was at first a clerk in the Bank of Australasia, and then learned farming at a station on the Wimmera river, Victoria. He was already writing stories for the *Australian Magazine*, when in 1867 he joined the staff of the Melbourne *Argus*. He also became secretary (1872) to the trustees of the Melbourne public library, and later (1876) assistant librarian. He founded in 1868 the Yorick club, which soon numbered among its members the chief Australian men of letters. The most famous of his books is *For the Term of his Natural Life* (Melbourne, 1874), a powerful tale of an Australian penal settlement, which originally appeared in serial form in a Melbourne paper.

See *The Marcus Clarke Memorial Volume* (Melbourne, 1884), containing selections from his writings with a biography and list of works, edited by Hamilton Mackinnon.

CLARKE, MARY ANNE (*c.* 1776–1852), mistress of Frederick, duke of York, second son of George III, married before she was 18 a Mr. Clarke, a stonemason, whom she soon left. She became in 1803 the mistress of the duke of York, then commander in chief. The duke's promised allowance was not regularly paid, and to escape her financial difficulties Mrs. Clarke trafficked in her protector's position, receiving money from various promotion seekers, military, civil and even clerical, in return for her promise to secure them the good services of the duke. These proceedings caused a public scandal, and in 1809 Col. Wardle, M.P., brought eight charges of abuse of military patronage against the duke in the house of commons, and a committee of inquiry was appointed, before which Mrs. Clarke herself gave evidence. The duke of York was shown to have been aware of what was being done, but to have derived no pecuniary benefit himself. He resigned his appointment as commander in chief and terminated his connection with Mrs. Clarke, who subsequently obtained from him a considerable sum in cash and a pension as the price for withholding the publication of his numerous letters to her.

Mrs. Clarke died at Boulogne on June 21, 1852.

See Elizabeth Taylor, *Authentic Memoirs of Mrs. Clarke* (1809); W. Clarke, "Life of Mrs. M. A. Clarke," in the *Annual Register*, vol. li. p. 61.

CLARKE, SAMUEL (1675–1729), English philosopher and divine, son of Edward Clarke, an alderman, who for several years was parliamentary representative of the city of Norwich, was born on Oct. 11, 1675, and educated at the free school of Norwich and at Caius college, Cambridge. The philosophy of Descartes was the reigning system at the university; Clarke, however, mastered the new system of Newton, and contributed to its extension by publishing in 1697 a Latin version of the *Traité de physique* of Jacques Rohault, which was used as a textbook till supplanted by the treatises of Newton himself.

Having taken holy orders, he became chaplain to John Moore (1646–1714), bishop of Norwich, who later presented him to the rectory of Drayton near Norwich. He subsequently became chaplain in ordinary to Queen Anne, who in 1709 presented him to the rectory of St. James, Westminster, in which year he became a doctor of divinity. As Boyle lecturer, he dealt in 1704 with the *Being and Attributes of God*, and in 1705 with the *Evidences of Natural and Revealed Religion*. These lectures, first printed separately, were afterward published together under the title of *A Discourse Concerning the Being and Attributes of God, the Obligations of Natural Religion, and the Truth and Certainty of the Christian Revelation, in Opposition to Hobbes, Spinoza, the Author of the Oracles of Reason, and Other Deniers of Natural and Revealed Religion*. During 1712 he published his celebrated treatise on *The Scripture Doctrine of the Trinity*. It is divided into three parts. The first contains a collection and exegesis of all the texts in the New Testament relating to the doctrine of the Trinity; in the second the doctrine is set forth at large, and explained in particular and distinct propositions; and in the third the principal passages in the liturgy of the Church of England relating to the doctrine of the Trinity are considered. This book involved Clarke in some trouble in the Convocation, which subsequently blew over.

In 1715 and 1716 he had a discussion with Leibniz relative to the principles of natural philosophy and religion, which was at length cut short by the death of his antagonist. A collection of the papers which passed between them was published in 1717 (*cf.* G. v. Leory, *Die philos. Probleme in dem Briefwechsel Leibnis und Clarke*, Giessen, 1893).

Clarke died on May 17, 1729.

See W. Whiston, *Historical Memoirs*, and the preface by Benjamin Hoadly to *Clarke's Works* (1738–42).

CLARKE, THOMAS SHIELDS (1860–1920), U.S. artist, was born in Pittsburgh, Pa., on April 25, 1860, and graduated at Princeton in 1882. He was a pupil of the Art Students' league, New York, and of the École des Beaux Arts, Paris, under J. L. Gérôme; later he entered the atelier of Dagnan-Bouveret, and, becoming interested in sculpture, worked for a while under Henri M. Chapu. As a sculptor, he received a medal of honour in Madrid for his "The Cider Press," now in Golden Gate park, San Francisco, Calif., and he made four caryatids of "The Seasons" for the appellate courthouse, New York. He designed an "Alma Mater" for Princeton university, and a model is in the library. Among his paintings are his "Night Market in Morocco" (Philadelphia Art club), for which he received a medal at the International exposition in Berlin in 1891, and his "A Fool's Fool," exhibited at the Salon in 1887 and now in the collection of the Pennsylvania Academy of Fine Arts, Philadelphia. He died in New York city on Nov. 15, 1920.

CLARKSBURG, a city in the heart of the coal, oil and gas fields of West Virginia, U.S., on the West Fork river at the mouth of Elk creek; the county seat of Harrison county. It is on Federal highways 19 and 50, and is served by the Baltimore and Ohio Railroad.

The population was 32,014 in 1950 and 30,579 in 1940 by the federal census. The city lies on a plain 1,100 ft. above sea level, surrounded by beautiful hills, in a rich agricultural and grazing, as well as mining, region. It has a large wholesale and retail trade.

Coal, natural gas and electric power are available for industrial uses, and the city has numerous manufactures including glass, chinaware, carbon electrodes, zinc boxes, crates, caskets, brick, tile, machinery, evaporated milk and other manufactures.

Clarksburg was settled in 1765, and was incorporated in 1785 by the general assembly of Virginia. It was named after George Rogers Clark. In 1917 the towns of Broad Oaks, Stealey Heights, Adamston and North View and several adjoining districts were consolidated with the old city of Clarksburg, which in 1910 had a population of 9,201.

A new charter was adopted in 1921, establishing a council-manager form of government.

In the next five years contagious diseases were practically eliminated, infant mortality was reduced far below the average for the country, a municipal playground system was developed, loss by fire was cut to a very low figure, public improvements costing $1,200,000 were made and the city debt was reduced by more than $500,000. The bonded indebtedness of the city of Clarksburg in 1950 was $396,000.

Clarksburg was the birthplace of "Stonewall" Jackson, of Nathan Goff and of John W. Davis.

CLARKSDALE, a city of northwestern Mississippi, U.S., on federal highways 61 and 49, 75 mi. S.W. of Memphis; the county seat of Coahoma county. It is served by the Illinois Central railway. The population was 16,539 in 1950 and 12,168 in 1940 by the federal census. It is an important cotton market and has cottonseed-oil and lumber mills and other factories.

The city was founded about 1830, and was first incorporated in 1882.

CLARKSON, THOMAS (1760–1846), English antislavery agitator, was born on March 28, 1760, in Wisbech, Cambs., the son of a schoolmaster. He was educated at St. Paul's school and St. John's college, Cambridge. Clarkson was first drawn to the subject of slavery by reading Benezet's *Historical Survey of New Guinea* (for a prize essay in 1785) on the question set by the vice-chancellor of the university: "Is it right to make men slaves against their will?" The English translation of the Latin of this prize essay, published in 1786, brought him into touch with William Dillwyn, Joseph Wood and Granville Sharp, and soon a com-

mittee of 12 was formed to do all that was possible to effect the abolition of the slave trade. Meanwhile Clarkson gained the sympathy of Wilberforce, Whitbread, Pitt, Grenville, Fox and Burke, and spent his days in travelling from port to port, gaining a mass of evidence which was partly embodied in his *Summary View of the Slave Trade, and the Probable Consequences of Its Abolition.* In May 1788 Pitt introduced a parliamentary discussion on the subject, and Sir W. Dolben brought forward a bill, which was passed in the house of commons on June 18, providing that the number of slaves carried in a vessel should be proportional to its tonnage. In the same year, Clarkson published an *Essay on the Impolicy of the Slave Trade,* but could get only nine men, personally acquainted with the facts of the trade, to promise to appear before the privy council. Wilberforce and the committee, however, had obtained other witnesses, and in May 1789 the former led a debate on the subject in the house of commons, in which he was seconded by Burke and supported by Pitt and Fox.

At the outbreak of the French Revolution, Clarkson hoped that the French would sweep away slavery with other abuses; but the hope was vain, and after six months in Paris during which he enlisted the sympathies of Necker, Mirabeau and the marquis de la Fayette, he returned to England and to his laborious search for further witnesses of the slave traffic. After his health gave way in 1794, Clarkson laid aside active work for writing, publishing in 1806 *Portraiture of Quakerism,* and, two years later, the *History of the Rise, Progress and Accomplishment of the Abolition of the Slave Trade by the Brit. Parliament.* The bill for the abolition had become law in 1807, and finally, in 1815, British diplomacy secured the condemnation of the trade by the other Great Powers. When the question of practical measures for its abolition was unsuccessfully discussed at the Congress of Aix-la-Chapelle in 1818, Clarkson personally presented an address to the emperor Alexander I, who communicated it to the sovereigns of Austria and Prussia. In 1823 the Anti-Slavery society was formed with Clarkson as its vice-president.

From this date until his death at Ipswich on Sept. 26, 1846, his chief works were *Thoughts on the Necessity for Improving the Condition of the Slaves in the British Colonies* (1823) and *American Slavery* (1845). His *Memoirs of William Penn* had appeared in 1813.

See T. Elmes, *Thomas Clarkson* (1854).

CLARKSVILLE, a city of northern Tennessee, U.S., on the Cumberland river at the mouth of the Red river, 42 mi. N.W. of Nashville; the county seat of Montgomery county. It is on federal highways 41A and 79, and is served by the Louisville and Nashville and the Tennessee Central railways and by river steamers. Pop. (1950) 16,246; (1940) 11,831 by the federal census. It is in a region of scenic beauty, at the centre of the dark tobacco belt. It has a large trade in both leaf and manufactured tobacco, purebred livestock and dairy products. There are flour mills, a snuff factory, mechanical rubber goods plant and other industries. Clarksville was settled in 1780, was named after Gen. George Rogers Clark and was chartered as a city in 1820. Dunbar's cave, an interesting cavern, is 3 mi. from the city.

CLASS. Class designates an aggregate of persons, within a society, possessing approximately the same status. The class system, or the system of stratification of a society, is the system of classes in their internal and external relationships. The class system is not identical with the sytem of power, *i.e.,* with the network of relationships in which behaviour is influenced by commands and coercion. It is not identical with the property system, in which the use of physical objects and their resultant benefits is reserved to those having specific qualifications (property rights). The class system is not identical with the occupational system. The class system is the set of relationships constituted by the granting of deference to individuals, roles and institutions in the light of their place in the systems of power, property, occupation, etc.

Deference is an action of respect or honour, associated with the feeling of equality or inferiority. By logical extension, sentiments of disrespect or disesteem, feelings of contempt and superiority, are also comprehended in the conception of deference. Deference is an act of implied judgment of the worth and dignity of a person, office or institution, made in the light of a scale of values. Deference is simultaneously an act of judgment regarding the person judged and the person judging.

Deference is expressed in ceremonial actions symbolizing sentiments of respect or inferiority; it is also expressed in etiquette, in actions granting precedence and in modes of verbal address and of verbal reference. It is expressed in titles and in the award of medals and insignia of rank. These are the "pure" expressions of deference. Deference, which is the acknowledgment of status, also works conjointly with the systems of power and of property. The readiness to obey or utter commands, the completeness of obedience and the extreme of imperiousness are very much affected by the sentiments of deference of the persons involved. The person who is very deferential toward his officer, his employer, his supervisor, etc., will more readily carry out his official superior's command than the person who feels little deference toward his official superiors and who has at the same time great self-esteem.

Bases of Class.—The deference which defines class position is granted to persons, offices and institutions in accordance with the deferring person's perception, which may be erroneous and which is almost always fragmentary and vague, of the characteristics of the person, office or institution being judged. A man is judged in accordance with the judging person's perception of his income and wealth, his occupation, his level of achievement within his occupation, his standard of living (including the location of his residence), his ethnic characteristics, his kinship connections, his educational level, his relationships to the main centres of the exercise of power in the society as a whole and in his particular institutions, such as business firms, churches, universities, armies, governmental departments, etc., and his associates, formal and informal. (His wife and children are usually granted deference corresponding to his status.) These various characteristics are not always evaluated in the same way in all societies. For example, in the United States the significance of kinship connection is less important than it is in China or Great Britain in affecting a person's social status (*i.e.,* the rank which is accorded to him by the deference judgment of the members of the society). Similarly, ethnic characteristics are more important in the United States than they are in France or Brazil, although they were diminishing in their significance in the United States at mid-20th century. Education has less significance as a basis of discrimination in the United States than it has in Germany, the Netherlands or Sweden. Occupation is probably less important as a basis of deference in the United States than it is in Germany, and it has continued to decline in the 20th century.

Within each category (*e.g.,* occupation), variations occur in the rankings which result from the feelings and judgments of deference. Scientists, for example, have moved up considerably on the scale in western countries, while the clergy has been undergoing a gradual decline over several hundred years. The military profession rose in the deference hierarchy in the United States after 1940, as it does everywhere when the society is militarily endangered.

The judgment which underlies the act of deference is a synthetic judgment which assesses simultaneously a large number of relevant characteristics. A process similar to that of averaging occurs. Hence, a very wealthy man who keeps low company and whose occupation is disreputable might rank lower in most people's opinion than a less wealthy person whose occupation is most estimable and who is an intimate of the great and worthy. In a society which regards the kinship bond as one of the primary ties, close blood relationship to a great person might compensate for a moderate income and a mediocre professional accomplishment in setting one person above another who is wealthier and more successful but who has no eminent ancestors.

Class System.—The class system is an imperfect equilibrium of innumerable individual acts of deference, both "pure" and "mixed" with elements of the occupational, property and political systems. The class system might be extremely inequalitarian, as

in the ante-bellum South, or it might be highly equalitarian, as in modern Norway. The members of the society might classify themselves and each other into a set of status classes which shade off into one another, or the classes might be sharply defined and distinguished from one another.

In an inequalitarian society, the acts of deference will express sentiments of great inferiority or superiority. The deference of the lower classes will be full of self-abasement before the superiors, and the latter will treat the former as barely human. European feudal society was like this. In contrast, there can be societies with a much higher degree of equalitarianism, in which the highest and the lowest both feel themselves to be part of a common community or humanity and in which accordingly there are not such sentiments of profound and far-reaching superiority and inferiority. Few persons in these societies feel themselves to be very much better or worse than anyone else. The modern western countries, and above all those societies which grew up on the frontiers without an inheritance of an elaborate inequalitarian class structure—namely, Canada, the United States, Australia and New Zealand—tend in this direction.

Although logically it is possible for any number of classes to be formed in a given society, once individuals of approximately similar status are grouped into classes, this does not, in fact, happen. There is a tendency for the society or its parts to act as if there were relatively few classes. Such classes as are recognized are not, of course, internally homogeneous, and persons within them make many distinctions which are not seen or acknowledged by those who are not in intimate contact with them. They are moreover practically never defined in the minds of most of those who refer to them. Persons who are especially "conscious" or sensitive about their own social status will try to define quite precisely the boundaries separating, among the persons with whom they come into face-to-face contact, those with whom they will associate and those with whom they will not associate on the grounds of their class status. Such "status-sensitive" persons are in most societies in varying but almost always small minorities, and even they do not have precise conceptions of the boundaries between classes other than those adjacent to their own class. Most of the class system is rather dimly differentiated in the minds of their members. Thus, the status judgment is not a precise judgment; it is only vague and approximate, in terms of higher and lower.

Boundaries are more precise in societies with an official system of stratification (*i.e.*, a titled nobility, a system of "estates" and a body of sumptuary legislation designed to demarcate class boundaries) and with relatively undeveloped mercantile, administrative and professional middle classes (like France in the 17th century or Russia before 1917). Even in such societies, however, the official stratification system covers in a differentiated manner only a small proportion of the social hierarchy. For the rest of the society, although retaining significance, it is too undifferentiated to suffice. In consequence, a further system of stratification of the type discussed in the preceding paragraph emerges spontaneously.

The sharpness of the boundaries of status groups is at its height in a caste system, because endogamy is a requirement there to an extent unattained in other types of stratification systems. There is of course a tendency for all status groups to be endogamous, but where personal affection is accorded some sway and where other considerations, such as personal beauty and personal merit, enjoy relative autonomy in competition with status considerations in the selection of marriage partners, this endogamy is always far from complete. In the caste system, however, endogamy reaches its highest level; in consequence, the inheritance of occupations in a static economic system and the strength of kinship ties add their force to already powerful status sentiments.

In all large societies, and particularly in those undergoing a moderate rate of change creating new roles, a considerable amount of upward mobility and some downward mobility are inevitable. It is especially pronounced in societies in which there are special institutional arrangements for training and selection and for the inculcation of standards of judgment which accord a high value to improved class status. This tends to raise problems relating to claims to higher status on the part of the recently ascended and denial of these claims by those with whom the recently risen persons seek to associate as a confirmation of their higher status. The denial of claims to deference of the "parvenu," because he is too new, or too crude, or too rich, or too contaminated with foreign connections or for whatever reasons, is a fertile source of alienation in society and a powerful factor in the promotion of change.

This phenomenon brings to the fore another property of the status system which merits mention. The discussion hitherto has proceeded as if there were, vagueness notwithstanding, a consensus in every society regarding the criteria for the granting of status as well as consensus in the assignment of the status of particular persons and institutions. This is not so. There is some disagreement and a great deal of sheer unconnectedness in the status judgments of all large societies. The groups which enjoy higher status positions in their own eyes and in the eyes of those adjacent to them will usually have a stronger view of their claims and merits than will those groups that feel themselves to be inferior. The lower classes, while acknowledging the superiority of their "betters," do so with reluctance and ambivalence. And in some instances some of the members of these classes deny outrightly that superiority. Ethically radical and politically revolutionary attitudes constitute the extreme form of denial of the claims of the "superior" to their superior status.

The human mind finds inferiority hard to accept in unadulterated doses, and some persons find it harder to take than others. In the lower and middle classes there is often a tendency to deny the validity of the criteria by which the upper classes have enjoyed their superior status. For example, in 18th-century France there was a widespread denial by the mercantile and professional classes of the legitimacy of kinship connections and of heredity as a basis for deference, while they praised the criteria of occupational proficiency and personal merit such as honesty, diligence and intelligence. (This outlook was expressed in the *Declaration of the Rights of Man and Citizen*, which declared "careers open to talent"). Ambivalence and resentment are widespread without, however, going so far as revolution—and even revolutionaries cannot completely expunge from their minds all the status criteria of the society they are revolting against, as is shown by the re-establishment of many of the prerevolutionary status patterns in the Soviet Union. Those whom the prevailing system of evaluation relegates to a lower status, even while sharing and acknowledging that status, simultaneously resent and deny it. The proportions of acknowledgment and denial vary among individuals and among societies, but it is safe to assert that it practically never approximates either extreme in any large society.

The imperfection in the integration of the class system is furthered by the limited range of attention and interest of a large proportion of the population. As a result, they do not participate as much in the larger class system as they do in their local class subsystem, comprising largely the persons with whom they have face-to-face contact. Only occasionally do they respond explicitly to the larger class system, and then they might do so dissensually.

Status System and Social Organization.—The conflict of classes is a reality of all large societies and cannot be eliminated. It is inevitable for the reasons given in the foregoing section. The lowly status is injurious to the sense of dignity of many persons, especially when it is reinforced by resentment against authority, however legitimate, and the desire for goods and services which cannot be acquired on the basis of income earned through the sale of services or goods in the market. The modern labour unions and employer's associations are responses to these facts. But even in societies in which labour unions are either not allowed or are shorn of the functions which they have developed in free societies, the conflict of classes persists, though it must operate through other institutions or even surreptitiously.

The conflict of classes is not always of constant intensity. It varies among societies and periods, and even at any one time in a given society only an extremely small proportion of the population will be much absorbed by the class conflict in its more active and organized form. (In the Bolshevik Revolution in St. Petersburg, only a few thousand persons were actively engaged.) Much

of the population participates by assent, a much smaller number participates by the payment of dues to organizations which promise to bring advantages to the class or some sector of it, and a far smaller number plays an active part in the organization. (It has been said that in Great Britain only 10% of those who vote for the Labour party belong to the party; of those who belong, only 10% ever come to meetings; and of those who come to meetings only 10% take an active part in party affairs, even of the most humble and occasional sort.) Thus what the Marxists call "class consciousness," which would be more precisely called "aggressively alienated class identification," is a rather uncommon phenomenon, even in modern industrial societies. Normal class conflict is fully compatible with a high degree of responsible citizenship and a considerable measure of social order.

Sentiments concerning class status and the individual's identification of himself in terms of a particular class status do, however, short of aggressively alienated class identifications, play a very permeative role in social life. Within the family, they affect parents' hopes for their children's future careers, spouses, friends and associates. They influence the extent to which a parent will exert himself to improve his economic lot so that the family will not only have more conveniences and amenities but so that it can also enjoy a higher status. It influences in large part the mother's decisions in the domestic economy and in the expenditure of income on various types of household articles. It affects the choice of place of residence and the choice of friends and associates. It is seldom the exclusive factor in such choices, but it is also seldom entirely absent.

Face-to-face relationships are of particular significance in the stratification system. It is in such relationships that individuals perceive their own status in the judgments of others. It is in such relationships that they can exhibit their own claims to the deference of others by acting, speaking and dressing in a certain manner. This is the reason why more discriminating and sensitive judgments are rendered about the nearby social environment than about those sectors of the society which are more remote. Yet considerations of class status do not overwhelm all other considerations in face-to-face relationships. The more human beings see of each other, the more they respond to each other as persons. They judge each other as persons worthy of being liked or disliked, of being loved or hated. Relationships which commence with status considerations foremost often develop into relationships in which personal affection or dislike becomes preponderant. Because personal relationships tend to begin in a situation of homogeneity in class status, friendships and marriages tend to fall within narrow ranges in class status. To the extent that they do not, they bring the classes rather closer together.

Face-to-face relationships, whether status or personal elements preponderate, play an important role in the status system as a whole. For those who are in the lower part of the status system, face-to-face relationships, usually with persons of approximately similar status, reduce the danger of denial of their status dignity out of resentment or contempt by those who are respectively lower or higher; while for those at the top of the status hierarchy, the tendency for like to associate with like confirms self-esteem and diminishes the danger of direct denial.

Thus, through the individual's sense of civic membership and his belief in its justice and through his face-to-face relationships and his limited focus of attention, inequalities in class status, which are an inevitability of large, differentiated societies, are rendered more tolerable to the sense of individual dignity. Therewith, his society is maintained in a state of equilibrium.

CLASS DAY, in American high schools, colleges and universities a day on which the members of the senior or graduating class celebrate the completion of their courses. The ceremony may take the form of a literary program involving the reading of the class history or the class poem, the delivery of the class oration or the presentation of the class play; it may include, too, the planting of the class ivy or the class tree or the burning of books in a huge bonfire to signify liberation from classroom routine. Formal presentation of a memorial gift to alma mater, athletic contests, campus singing, receptions, banquets and other forms of entertainment reflecting the traditions of the institution may also characterize the event.

CLASSICAL EDUCATION. In the universities of Great Britain archaeology, anthropology, numismatics, epigraphy, psychology, philology and geography are recognized as essential to the classical scholar who would understand and describe clearly conditions of life in the ancient civilizations. Western Europe has learned to realize the measure of its debt to Greece and to estimate the nature of the legacy it has received from imperial Rome. The precision of classical literature leads to a sense of proportion, a standard of values, a respect for the truth of words and accuracy of thought. In the principal secondary schools classical studies are not losing ground (*see* PUBLIC SCHOOLS). As historical links exist with university foundations, the great public schools conserve the best traditions of classical scholarship. In the ordinary secondary schools Latin is taught as one of several competing subjects. Of methods in use the following is one of the most interesting and most original.

The Direct Method.—The direct method of teaching foreign languages aims at connecting the foreign word, phrase or sentence directly with a thing, act or thought, without the intervention of English. When a certain number of words have been learned, new ones are explained by a paraphrase in the same language; and in the final stage, the literature is read and discussed in the original.

A working system has been devised by which this method can be applied to Latin and Greek. Time is saved, because the whole lesson is taken up with the language; attention is kept, because the language used is real to us instead of artificial; understanding is easy, because what we do or see explains what is said. In proportion as we exclude English words from our minds, we come to think in the language, and a feeling for its idioms and turns of speech is soon developed. Since the vocabulary used is simple and deals with everyday and familiar life, the attention can be exercised on the peculiar inflections which distinguish the ancient languages. Grammar is learned after use, not before, and is therefore less irksome. Short exercises are used, to illustrate grammar; they do no harm if they come in their proper place (after use) and in due proportion. With the reading book, from the very first all is read aloud and explained in the same language, the explanations being written and learned. English is never used unless it cannot be helped. When the pupils are fit to read an author, they know enough to dispense with English. Formal translation from English into Latin or Greek, the most difficult of all exercises, is reserved for the last two years of school life. Whoever does not understand must ask. No one is blamed for not understanding; all are blamed for not asking.

In the reading lesson every line of the matter is read aloud; and very often the mere manner of reading shows whether the text has been understood, and if it has not, it can be explained simply by correct reading. By reading the memory is filled, the ear is taught, the taste is trained; the language, in short, is learned in the most effective way. So much so that verses of all sorts, lyrics included, are written with ease by imitation. But the real merit of this method lies in its effect on the learner. From the first stage to the last, the learners are willing to learn and happy in learning. (C. Br.; W. H. D. R.)

The United States.—Classical education in the United States began with the founding of Harvard college and the Boston Latin school in about 1638. Following the English model (probably Cambridge) the only requirement for entrance to Harvard was the ability to read and speak Latin, and some knowledge of Greek forms, and this was also the aim of the Latin school. All lectures were in Latin, the curriculum consisted almost wholly of the

classics and students were required to speak Latin on the campus. The subsequent progress of classical education has been divided roughly into three periods: the pre-revolutionary period, the period to the close of the Civil War, and the modern period.

During the first period admission requirements remained much the same, as at Harvard, even arithmetic was not required until 1693, and then not universally. In the colleges the classics remained supreme, although arithmetic, geography and anatomy were included in the curriculum of William and Mary in 1693, and physics in that of Yale in 1701. Also the forerunner of the University of Pennsylvania, under the influence of Benjamin Franklin, made considerable provision for science, and an impressive programme in science and history was announced by Columbia in 1754, which, however, was not adhered to.

The middle period was one of great educational expansion. Many new colleges and secondary schools were founded, and the States began to make provision for higher public education in the State universities. Public high schools also began to multiply. The curricula of the colleges were greatly extended, and the appearance of new subjects in the requirements for entrance involved provision for them in the fitting schools. At first Greek and Latin, later Latin alone, were obligatory on all candidates for degrees, and while in some academies, notably those for girls, and in the State universities, the tendency was to greater freedom, still the general tone of education was cultural, interpreted as classical.

The modern period has been one of revolution, both in ideals and practices. The carrying out of the theory of universal education, and the rapid growth of industrialism demanded greater provision for vocational and scientific training. The public high schools still clung closely to the classical tradition but they showed the new influence in the great broadening of their curriculum. Where this was not done, vocational and trade schools discarded the classics for a more immediately practical training. In higher education, either separate scientific and technical schools were established, or increased provision was made for science in the colleges and universities, and modern languages and the social sciences vied with the natural sciences in pressing their claims.

Room for the new subjects could only be obtained at the expense of the classics. The first to be seriously affected was Greek, which, though vigorously defended, had by 1928 been eliminated almost entirely from the curriculum of the secondary schools, and was studied by very few undergraduates in college. Latin also was severely curtailed and at one time seemed likely to go the way of Greek. Since the World War, however, there has been some reaction in favour of Latin in the colleges and it has continued to hold a large place in the schools, partly because it is still an important requirement for entrance to college. It was estimated that over 1,000,000 pupils were studying Latin in the schools in 1928. It is not, however, the Latin of former days. Under the attacks of the new psychology and the advocates of practical studies the teaching of Latin, which formerly had been largely a mechanical preparation for entrance examinations, has now been adapted rather to the immediate needs of the pupils studying it. In 1920 the general education board arranged with the American Classical League to conduct an investigation of the classics (chiefly Latin) in the secondary schools. In the report, published in 1924, the aims of the teaching of Latin were set forth as follows: to read and understand Latin; to increase the pupil's ability to understand the Latin element in English, and to read, speak and write English; to develop historical and cultural background, correct mental habits and right attitudes towards social situations; to increase the ability to learn foreign languages; and to give an elementary knowledge of the principles of language structure. In the furtherance of these aims extensive recommendations were made as to curriculum and method of teaching. These have been very widely adopted and the text-books are rapidly being reconstructed to carry them out. As a result the outlook is bright for continued support of Latin, particularly in the secondary schools, as an important element in American education. (G. L.)

France.—In France during the greater part of the 19th century, the position of classics in secondary schools was supreme. They alone led to the baccalaureate:—sole entrance to the universities and the liberal professions. Towards the end of the century, a strong movement in favour of modern languages and science arose. In 1898 a parliamentary committee was appointed to inquire into the subject. They reported in 1899, but it was not till 1902 that their conclusions were embodied in the establishment of four alternative courses, a full classical, a Latin-modern languages, a Latin-science and a purely modern course, all of which led to the university. These courses remained unchanged for nearly 20 years, and during that period the classical candidates for the baccalaureate, who in 1904 numbered 3,337, fell to 2,775 in 1924. The Latin-modern rose from 1,217 to 5,964, the Latin-science from 2,229 to 5,241 and the science-modern languages from 2,742 to 5,241. Thus, while Greek declined, the students taking Latin increased more than twofold and amounted to over 70% of the candidates.

The World War brought its aftermath of discussion. In 1922 M. Bérard, the minister of public instruction, proposed to make Latin and Greek obligatory in the earlier stages, and to cut down the courses of two (classical or modern). A bitter struggle followed, in which the majority of expert opinion was against him. None the less, in May 1923 the President of the republic issued a decree embodying the proposals of M. Bérard, and requiring a certificate of proficiency in Latin and Greek from all future candidates for the baccalaureate. A year later the Ministry fell and was replaced by a Radical one. The two courses have been maintained, but classics are no longer obligatory for all, though as the curricula of the girls' schools have now been assimilated to those of the boys, a classical education is equally open to the former.

Germany.—In Germany up to the end of the 19th century, classics were likewise supreme. The full classical school, the Gymnasium, was with one or two exceptions the sole avenue to the university and liberal professions. In 1890, at the instance of the Kaiser, a conference was called in Prussia. Its conclusions, largely embodied in the curricula of 1892, reduced the number of hours given to classics and dethroned the latter in favour of the mother tongue, while the universities were thrown open to pupils from the Realgymnasium (Latin-modern school) and to a large extent to those from the Oberrealschule (modern studies school). Similar reforms had already been adopted by other German states. The next outstanding feature was the founding of Reformgymnasia, where the first language was French, Latin not being introduced till the fourth and Greek till the sixth year, both being taught intensively. This type was largely adopted in Prussia before the war. Classical studies have been open to girls since 1904, but the number taking them has not been very great. For education since the war, no statistics are available, but according to one authority, "the desertion of schools with Latin as a central subject is general." Others are less pessimistic and the prevailing opinion seems to be that the Reformschulen will ultimately be the future type of German classical education.

Italy.—Of the other European countries, the most interesting one from the classical standpoint of view is Italy. Here, thanks to the reforms of Gentile, there has been a strong reaction in favour of classics, and by the royal decrees of May and Nov. 1922, classical studies have been strengthened in the higher schools not only of the purely classical but also of the scientific type. Latin in fact is now obligatory in all secondary schools. Room for this increase has been found by cutting down the number of subjects and reducing the time given to mathematics; the main object of the reform being to replace the former encyclopaedic aim of the school by a cultural one based on direct knowledge of the classics. Latin is also a principal subject in the girls' high schools.

Belgium.—In Belgium again the position of classics appears to have improved. A committee was appointed after the War to consider the reform of the school syllabuses and the position of Greek. As a result, classics have been maintained in the Athénées Royales (high schools) and further Greek and Latin can be studied in those *écoles moyennes*, which are not within convenient distance of an athénée.

Norway.—In Norway, likewise, the classics have recovered ground. In 1896 Greek was entirely banished from secondary education; to-day it is included in one section of the higher schools (gymnasia), and can be studied by girls as well as boys.

Czechoslovakia.—The republic of Czechoslovakia has largely maintained the previous types of education, which were on German lines and as the system is co-educational, classical or Latin studies are equally open to girls.

Sweden.—In Sweden classics seem to have somewhat lost ground. The pupils following a full classical or Latin course, who ten years ago were in a majority, are now outnumbered by those taking modern studies. (C. Br.; W. H. D. R.)

Latin American Countries.—In Latin American countries less attention is given to study of classical languages than in other countries whose culture is derived from the classical heritage. In the first place secondary schools in most Latin American countries were established at a time of reaction against schools maintained by the teaching orders which had emphasized the classical basis in secondary education. Secondly, universities have consisted in the main of loosely associated faculties for professional preparation and are only just beginning to permit the study of liberal art subjects either in existing faculties of philosophy as in Buenos Aires, or in newly created faculties as in Santiago. In these the study of the classics may find encouragement in time. Thirdly, the secondary school curriculum has developed by an accretion of subjects and unlike the development in European countries and the United States, little provision has been made for options or for differentiated courses. Consequently, when the list of subjects to be carried became too burdensome, a solution was found by dropping those subjects, especially Latin, which the pupils found too difficult and whose utility was not recognized by the parents.

The situation in general may be illustrated from the practices of some of the leading Spanish American countries. In the Argentine a movement to make Latin an optional subject began as early as 1870 and was realized in 1886; in 1891 proposals began to be made to drop it and by 1901 it disappeared entirely except in three schools that enjoy special privileges of autonomy. Greek had disappeared as early as 1863. In Chile Latin ceased to be required for graduation from a secondary school in 1877 and gradually disappeared. In 1925 an inquiry elicited the opinion that room should be found in certain schools for the study of Latin with or without Greek. It is significant to note, however, that all students in the Instituto Pedagogico, the institution for training secondary school teachers, must take Latin, if they wish to become specialists in Spanish or any modern foreign language. In Uruguay Latin grammar was taught in the first two years of the secondary school course in 1889 but was dropped in 1909. Latin is required in Mexico of students who plan to enter the faculty of law of the university.

In Brazil the exception to the general practice may be found, for here Latin is required for four years of the six year secondary course and Greek survives in some schools on an optional basis.

The secondary school situation is reflected in the universities. The general absence of liberal arts faculties has been noted. The small number of professors of Latin or of Greek is to be found at the Universities of Buenos Aires and La Plata in the Argentine, in the Instituto Pedagogico of the University of Chile and in the University of Concepción in Chile, and in the private Colegio Mayor de Nuestra Señora del Rosario in Colombia. Latin, if not Greek, is still cultivated by the ecclesiastical orders and it is under the direction of their members that those who are interested in the classics may pursue their studies beyond the level of the secondary schools. (I. L. K.)

CLASSICS. "What need to speak of Democritus? . . . Who does not place this philosopher above Cleanthes, Chrysippus, and the others of later times? These appear to me to be fifth class as compared with him" (*qui mihi cum illo collati quintae classis videntur*). Thus Cicero, *Academics* ii. 23, 73. The expression "fifth class," natural and familiar as it sounds to a modern ear, has an interesting history. Among the constitutional reforms ascribed to Servius Tullius, the sixth king of Rome, was the division of the citizens into five *classes* according to the amount of their property as determined from time to time by a census. Hence the fifth *classis* denoted the lowest class of citizen from the point of view of wealth. It appears from Aulus Gellius, vi. 13, that the term *classicus* was applied only to the first or highest *classis:* "Not all those who were enrolled in the five classes were called *classici,* but only the men of the first class, who were rated at 125,000 *asses* or more. 'Below class' was the appellation given to those of the second or other classes rated at a lower sum. . . . This I have briefly noted because apropos of M. Cato's speech in support of the Voconian law the question is often asked what is meant by *classicus* and what by 'below class.'" When or by whom the term was first used in a metaphorical sense to denote an order of merit, we do not know. This extension is already implied in the *quintae classis* of Cicero. But the first extant example of *classicus* to denote the highest order of literary merit seems to be Aulus Gellius (2nd century A.D.) xix., 8, 15. Julius Caesar in his treatise *De Analogia* had laid down the doctrine that *quadrigae* (in the plural), even of a single chariot, is the only correct use, and conversely that *harena* (sand) is only used correctly in the singular. Gellius narrates a conversation on the matter with M. Cornelius Fronto, who supports the opinion of Caesar, and concludes with the words: "Now go, and when you have time see if you can find *quadrigae* in the singular, or *harena* in the plural, written by any of the elder orators and poets—I mean, by one who is a *classicus* and *assiduus* writer, not one who is *proletarius.*" *Assiduus* seems to have been applied more generally to members of the wealthier classes, being equivalent to *locuples* and indicating a person of property (Cic. *Rep.* ii. 22–40; *cf.* Aul. Gell. xvi. 10). *Proletarii,* on the other hand, were the poorest citizens who contributed nothing to the state but their offspring (*proles*); (*cf.* Aul. Gell. *l.c.,* Cic., *Rep.* ii. 22–40). In modern times the word "classic" is in common use of any author who has tholed the assize of the centuries, or even of one who in his own time is classed with those who have: Macaulay, *Boswell's Life of Johnson:* "What a singular destiny has been that of this remarkable man! To be regarded in his own age as a classic and in ours as a companion!" But the term "classics" has been long and widely used to denote more especially the literatures of ancient Greece and Rome, and in that sense it is employed here.

THE LITERATURE OF GREECE

Commencing with Homer, ancient Greek literature may be considered as extending down to Justinian (A.D. 527), thus covering a period of something like 14 centuries. Within this period it is usual to distinguish (1) the Classical period extending from Homer to the death of Alexander (323 B.C.), (2) the Alexandrine period from 323 B.C.–A.D. 100, (3) the Post-Alexandrine period A.D. 100–529. The Byzantine period from 529 to the capture of Constantinople by the Turks produced no Greek literature of first-rate importance.

The unique feature of Greek literature and one which lends it a unique interest, in addition to its intrinsic merit, is its originality. The Greeks invented all the great types of literature alike in poetry and in prose. Thus epic, lyric, elegy, tragedy, comedy in poetry; history, rhetoric, philosophy in prose—were all alike, as the very names declare, the invention of this extraordinarily gifted people. A people whose literature is based upon foreign models may devote themselves to the cultivation of the different types in any order of succession, or may cultivate the several types in the same age with equal enthusiasm. But the Greeks, having no models, discovered and developed the different forms in logical succession, one being evolved from the other according to the spiritual and social impulses of the time. Moreover, when any one form was developed to its full perfection, they seem to have passed on to another. Hence it is that in Greek literature more than in any other we can speak of a given age as the age, not of this individual writer or of that, but as the age of a particular form of literature.

Greek Poetry to 323 B.C.—Greek literature begins with the Homeric epic, represented for us by the *Iliad* and the *Odyssey.*

There is evidence enough in these poems that they are themselves not primitive in the sense of being a first pioneer effort in the writing of epic. The recurrent epithets and conventional formulae, nay, the very metre in which they are written, imply a long ancestry of poetic practice and experiment. What makes these two epics unique among the epics of all literature is that on the one hand they are sufficiently near the dawn of literature to have yet upon them the dew of the morning, to have all the directness and simplicity and naïveté which we associate with primitive poetry; and on the other hand they belong to a stage of development so far advanced as to have outlived the imperfection of form, and the triviality or vulgarity of thought which, in early poetry, are apt to offend the cultured reader. Moreover, they have developed at once a language and a metre—from what elements and by what stages developed we do not here enquire—which together constitute a vehicle for narrative epic such as no other people have ever possessed. And because of this union of a language uniquely suited to the metre, and a metre uniquely suited to the language, the union has resisted divorce. Down to the latest times, the same language and the same metre continued to be the one medium of Greek epic. The Romans borrowed the metre, but in Roman hands its character is entirely changed, and whatever other merits Roman epic may possess, they are assuredly quite other than the merits of Homeric epic. Attempts to transplant the hexameter (*q.v.*) into English were—for reasons which cannot be here elaborated—foredoomed to failure. And what has become the favourite medium for epic in English, viz., blank verse, suffers in comparison with the Homeric hexameter much in the same way as the Roman hexameter does in comparison with the Greek, a lack of lightness and mobility: defects which both in Roman epic and in English, find their compensation in certain other qualities which are, however, of value only from the point of view of poetry in general, assuredly not from the point of view of epic poetry in particular.

Alongside the Homeric type of *Epos*, *i.e.*, the epic of chivalry, which had for its subject the story of war and adventure in the heroic age, the *κλέα ἀνδρῶν* of *Iliad*, ix. 189, etc., the Greeks early developed quite another type of *Epos*, which had for its business to inculcate the traditional wisdom of the race. As Hesiod, the earliest of the didactic poets, belongs roughly to the Homeric age—in Greek tradition Homer and Hesiod are regularly coupled together and regarded as contemporaries: Herod ii. 53: Plato, *Rep.* 363 A; 377 D; 599 D; Aristoph., *Ran.* 1,033 *seq.*—he naturally chose for his didactic poems the Homeric hexameter. Two didactic poems are ascribed to Hesiod—the *Theogony* and the *Works and Days*. True to Greek custom the hexameter remained down to the latest times the recognized medium for didactic poetry. The *Theogony* of Hesiod may be regarded as the forerunner of the philosophical poems bearing the title *Περὶ Φύσεως* (On Nature), of which three were especially notable: (1) that of Xenophanes of Colophon, the founder of the Eleatic school of philosophy, in the second half of the 6th century, whose protest against the unworthy ideas of Homer and Hesiod regarding the gods is well known:

> *πάντα θεοῖς ἀνέθηκεν Ὅμηρός θ' Ἡσίοδός τε*
> *ὅσσα παρ' ἀνθρώποισιν ὀνείδεα καὶ ψόγος ἐστίν . . .*
> *ὡς πλεῖστ' ἐφθέγξαντο θεῶν ἀθεμίστια ἔργα*
> *κλέπτειν μοιχεύειν τε καὶ ἀλλήλους ἀπατεύειν*

("Homer and Hesiod ascribed to the gods everything that men think scandalous and shameful. . . . They recounted very many wrongful acts of the gods—theft, fornication and deception of each other."); (2) Parmenides of Elea, the most distinguished of the Eleatics (*c.* 504 B.C.); (3) Empedocles of Acragas (born *c.* 495 B.C.), whose poem was the direct model of the *De Rerum Natura* of Lucretius (Lucret. I. 726 *sqq.*). On the other hand Hesiod's *Works and Days* was the prototype of a long series of poems of the practical type, including the *Theriaca* and *Alexipharmaca* of Nicander of Colophon, the *Phaenomena* of Aratus, the *Halieutica* of Oppian the Cilician, the *Cynegetica*, attributed to Oppian, but the work of a later poet from Apameia in Syria—all of which are extant, and of the no longer extant *Halieutica* of Caecalus, Numenius, Pancrates, Poseidonius, as well as of the *Georgics* of Virgil, the *Cynegetica* of Grattius and Nemesianus in Latin.

To the epic age succeeds that of iambus and elegy. Iambus, as a literary form, although it had a long life, from Semonides of Amorgos (*c.* 625 B.C.) to Callimachus and Herondas in Alexandrine times, never achieved an important independent existence. The reason is sufficiently obvious. The iambus—a short syllable followed by a long (*see* IAMBIC)—as the chief component of ordinary prose speech is not of itself adequate to support an independent type of poetry. It is true that it does so in modern literature, as for example in English. But the mere name "blank verse" by which the iambic metre is usually described practically admits that "blank verse" differs from ordinary prose in either one of two ways. Either it betrays its poetic intention by an exactness of rhythm which is repugnant to prose, *i.e.*, by a rhythm the recurrences of which produce metre, or by the quite adventitious use of rhymed endings, "the invention," as Milton says, "of a barbarous age, to set off wretched matter and lame metre." But in any case the iambus as an independent form never attained first-rate importance in early times, nor does its recrudescence in Alexandrine times in any way suggest that it could ever be of great importance by itself. As we shall immediately see, in conjunction with lyric metres in tragedy and comedy it was able to find a place which could not have been taken either by the epic hexameter or by any other metre.

Elegy, on the other hand, consisting of alternate hexameters and pentameters (*qq.v.*) is the nearest approximation to epic. But there does not seem ever to have been the least danger in Greek of confusing the function of elegy with that of epic. The name *ἔλεγος*, *ἐλεγεῖον*, *ἐλεγεῖα*, *ἐλεγεία* is of quite uncertain origin, but everything tends to show that from the first it was essentially of a plaintive character, being regularly accompanied not by the lyre, the instrument of mirth, but by the flute, the instrument of mourning (*ἔλεγοι οἱ πρὸς αὐλὸν ᾀδόμενοι θρῆνοι*, Didymus *ap.* schol. Aristoph., *Av.* 217; Pausan. x. 7.5; *cf.* Aesch., *Ag.* 990, *Eumen.* 332; Soph., *Tr.* 640 *sqq.*; Eurip., *Hel.* 85, *Iph. Taur.* 146, 1091; Ovid, *Ep.* xv. 7, *Amor.* iii. 9.3; Hor. *c.* i. 33.2). Who invented the form is not known (Hor. *A.P.* 77).

Quintilian, curiously enough, regards Callimachus as the chief elegiac poet, and Philetas of Cos as the second (x.1.58), and Propertius regards these two poets as his masters (v.1.1). In any case the Greeks, at a very early period, extended the range of elegy far beyond the dirge or lament to poems of war and of traditional wisdom. But they did not, like Ovid, use the elegiac metre as practically a substitute for the epic hexameter. The text of Theognis (of Nisaean Megara, *c.* 500 B.C.) in two books, is the longest elegy that has come down to us. It hangs together very loosely and is rather a series of elegies of varying length than a single poem. In the Alexandrine age we have various fragments of the *Aitia* of Callimachus and the whole (with one slight lacuna) of his Hymn entitled the *Bath of Pallas* (*Λουτρὰ Παλλάδος*) in 142 lines. But the type of elegy which was carried to the highest perfection by the Greeks was what is generally known as the epigram, a highly polished poem in elegiacs, varying in length from a single distich to half-a-dozen or more, and of very various content. This type makes up the great bulk of the collection known as the Greek Anthology (*q.v.*).

Next in order of development and, of course, to some extent coincident in point of time, we have lyric poetry or song, and this of two types—on the one hand the individual or personal song, and on the other the choral lyric. Of the first the remains are exceedingly meagre and, indeed, are chiefly confined to the fragments of Alcaeus and Sappho. Of the high merits of the latter the Greeks seem to have entertained no doubt, and modern critics—whether professed classical scholars or amateurs like Swinburne—have vied with one another in finding words of enthusiastic and extravagant eulogy.

Of choral lyric, on the other hand, we have very extensive remains, both as an independent literary form, and as an element of tragedy and comedy. Of the first our most important representative is Pindar, of whom, apart from considerable fragments,

we possess some 45 odes classed—not always correctly—as epinician odes, or odes in celebration of victors in the games (Olympian, Pythian, Nemean, Isthmian). We have also recovered in recent years (1896) a papyrus containing a certain amount of his junior contemporary Bacchylides, about six poems being practically complete. The manner in which these poets succeed in contriving that a poem which is in the first instance written to celebrate such an ephemeral event as a victory in the games should be of permanent appeal, is a very interesting literary study, which will be more fittingly discussed in connection with Pindar (*q.v.*).

The next important development is the drama, including, of course, both tragedy (with the Satyric drama) and comedy. While in all likelihood these two species of drama were of contemporaneous origin, tragedy was the earlier to attain a high degree of perfection: Aristotle's statement (*Poet.*, c. v., 1449ª36) of the comparatively late date at which comedy was not formally recognized by the State, is confirmed by epigraphic evidence from which it appears the comedy was not officially recognized by the State until 488–487 B.C., while Thespis, the father of Attic tragedy, is said to have produced his first tragedy in 534 B.C.

Tragedy is said by Aristotle to have originated *ἀπὸ τῶν ἐξαρχόντων τὸν διθύραμβον* ("with the leaders of the dithyramb," *Poet.* 4.1449ª10), and this seems to agree with the facts. The literary development of the dithyramb in honour of Dionysus is associated with the Dorian Corinth, and Greek tragedy on the face of it seems to be a combination of Doric choral song with Ionic dialogue. The great period of Attic tragedy is the 5th century B.C. and is mainly represented for us by the remains of the three great tragedians, Aeschylus (525–456 B.C.), Sophocles (496–406 B.C.) and Euripides (*c.* 480–406 B.C.) (*qq.v.*). We also possess Euripides' *Cyclops*, the only extant Satyric drama, the recently discovered *Ichneutai* of Sophocles being in a fragmentary form. The usual method of the production of tragedy in the 5th century was in the form of a trilogy of tragedies followed by a *δρᾶμα σατυρικόν* (Satyric drama). The relation of this last form of drama, in which the spirit is in the vein of comedy, while the chorus is a choir of satyrs, to tragedy is a subject of debate. Aristotle regards the satyric element as original (*Poet.* 4.1449ª19) which seems the more probable view. On the other hand it has been held, both in ancient and modern times, that the satyric element was not original. According to an old view it was superadded to tragedy by way of comic relief (Hor., *A.P.* 220 *sqq.*). Prof. Ridgeway, holding that tragedy originally was non-Dionysiac, but connected with the solemn commemoration of the dead, derives *saturoi* from *Satrae*, a Macedonian tribe, and holds that the introduction of the satyric element was coincident with the introduction of the worship of Dionysus at Athens towards the end of the 7th century B.C.

Comedy originated, according to Aristotle, *ἀπὸ τῶν τὰ φαλλικὰ (ἐξαρχόντων) ἃ ἔτι καὶ νῦν ἐν πολλαῖς τῶν πόλεων διαμένει νομιζόμενα*, "with the leaders of the phallic songs which still survive in many cities as an institution" (*Poet.* 4.1449ª 11). This again seems a very probable account, the name *κωμῳδία* being derived, not from *κώμη*, village, but from *κῶμος*, a company of revellers (Arist., *Poet.* 3.1448ª36 ff). These phallic songs were sung (Aristoph., *Ach.* 261, "And I will follow and sing the phallic song,") by lewdly dressed processionalists, *phallophoroi*, and the intention was by mimetic symbolism to promote fertility (Athen. 621 E. For their dress and procedure *cf.* Athen. 622 B). Similar customs exist even at the present day, *e.g.*, in Macedonia.

The Alexandrine scholars distinguished Attic comedy into Old (*παλαία*) and New (*νέα*), the further distinction of Middle (*μέση*) comedy dating only from the time of Hadrian. For us the only poet of the Old Comedy of whom a complete play is extant is Aristophanes (*q.v.*, *c.* 446–385 B.C.).

We note some features which belong to the earliest stages of comedy. We notice first the frequency with which the chorus, from which the comedy takes its name, represents some species of animal. Similarly we hear of plays by Magnes entitled *Birds, Frogs, Gall-wasps* (*cf.* Aristoph. *Eq.* 522 *seq.*). It is impossible to doubt that tragedy in the same way got its name from the fact that the chorus was represented as He-goats (*τράγοι*), or that the Satyric drama was also named from its chorus of He-goats (*σάτυροι*, *cf.* שעירים) Is. 13.21. Puck = Bock (Ger.) = Buck (Eng.). Then we have the *Parabasis* or address to the spectators, also primitive, as is the *Agon* or debate between two opponents. The later plays of Aristophanes show a considerable divergence from the earlier. The three earliest plays—*Acharnians, Knights, Wasps*—have a fully developed *Parabasis*, while in three of the later plays—*Lysist., Eccl., Plutus*—the *Parabasis* has completely disappeared. Similarly with the place of the chorus in general. Thus in the *Plutus* the office of the chorus is confined to dialogue, and there are no choral songs. The later plays thus exhibit tendencies which are carried still farther in the New Comedy. Menander (*q.v.*, *c.* 323–293 B.C.), though his date falls in the Alexandrine period, has nothing to do with the Alexandrines: he declined the invitation of Ptolemy I. to go to Alexandria and remained in Athens. The characteristic feature of his comedy seems to have been faithful representation of life (*cf.* Syrian. in Hermog. 2 p.23 8 Rabe). Although his scanty remains have been greatly augmented in recent years by discovery of papyri, we still have no complete play. The word *Χοροῦ* appears after *Epitrepontes* 201: otherwise, Chorus, *Agon, Parabasis* have completely disappeared.

Greek Prose to 323 B.C.—While prose doubtless preceded poetry, prose as a developed literary form is later than poetry. Hence the history of Greek prose down to 323 B.C. is a much shorter story than that of Greek poetry in the same period. If we take the three great literary types of prose to be history—the novel or romance, when it is developed is merely fictitious history, *cf.* Bacon, *Advanc. of Learning* ii.: "Poetry . . . in respect of matter is nothing else but feigned history, which may be styled as well in prose as in verse"—oratory, philosophic essay or dialogue—the natural order of development is history (including the fable or apologue, and the speech as subsidiary elements), oratory, philosophic prose.

Three *historians* in this period are represented by complete works. First we have the *History* of Herodotus (*q.v.*, *c.* 484–425 B.C.). His conception of the function of history is clearly stated in his opening paragraph: *Ἡροδότου Ἁλικαρνησέος ἱστορίης ἀπόδεξις ἥδε, ὡς μήτε τὰ γενόμενα ἐξ ἀνθρώπων τῷ χρόνῳ ἐξίτηλα γένηται, μήτε ἔργα μεγάλα τε καὶ θωυμαστά, τὰ μὲν Ἕλλησι, τὰ δὲ βαρβάροισι ἀποδεχθέντα, ἀκλεᾶ γένηται, τά τε ἄλλα καὶ δι' ἣν αἰτίην ἐπολέμησαν ἀλλήλοισι.* "This is the history of Herodotus of Halicarnassus, published in order that what has happened may not be forgotten of men by the passing of time, and that the great and admirable actions of the Greeks and the barbarians may not become unappreciated, and in particular the reasons for the war between them." His object is thus simply to prevent the achievements of the past from being obliterated by time; he has no notion that a knowledge of the past should have any bearing either on the conduct of the present or the anticipation of the future. As to his conception of the duty of the historian, we need only note that he travelled widely and used all the sources of information open to him, whether monumental or oral. In matters of dispute, he endeavours to state both sides of the question, but with refreshing candour he warns the reader that he does not affirm the truth of either side (ii. 123, vii. 152). On any view Herodotus must always be regarded as one of the most charming of historians. His air of candour and naïveté (Quintil. x. 1.73) heightened by the archaic suggestion of the dialect (Ionic) in which he writes and the simple structure of his composition (*λέξις εἰρομένη*), his digressions, his picturesqueness give him an irresistible appeal.

Thucydides of Athens (*q.v.*, *c.* 460–*c.* 396 B.C.) wrote a *History of the Peloponnesian War*, now divided into eight books. He tells us (i. 1) that he commenced to write his *History* as soon as the war began, as he foresaw that it was likely to be a greater and more important war than any that had yet taken place, an opinion founded on the fact that both the Athenians and the Lacedaemonians were at the height of their power, while the other Greek States were likely to range themselves on the side of one or other of the protagonists in the conflict. His failure in 424 to save Amphipolis led to his going into exile, a circumstance which

gave him the opportunity to study the war from both sides (v.26). His conception of the function of history differs markedly from that of Herodotus. His idea is that a knowledge of the past is the best guide to the future (i. 22). Two peculiarities of his *History* must be noted. First the annalistic order of treatment. That is to say, instead of treating an episode of the war as a whole, he narrates events *κατὰ θέρος καὶ χειμῶνα, i.e.*, after the form of a diary—all the events of a particular summer are grouped together, however unconnected they may be, and these are then followed by the events of the ensuing winter. Another remarkable feature is the use of set speeches composed in a highly elaborate form—showing the exaggerated use of the antithesis which characterized early Greek rhetoric. His own account of the conception of these speeches is given in i. 22: "as to the speeches delivered by the several combatants either when they were about to go to war, or when they were already involved in it, it was difficult both for me in the case of speeches which I heard myself, and for those who reported to me speeches from other quarters, to remember the exact words. I have written what it seemed the various speakers would have said if they spoke to the purpose, while keeping as close as possible to the general sense of what was actually said."

The third of the historians is Xenophon of Athens (*q.v.*, *c.* 431–*c.* 355 B.C.). His *Hellenica* in seven books continues the history of Greece from the point reached by Thucydides (411 B.C.) down to the battle of Mantineia in 362 B.C. His *Anabasis* in seven books describes the expedition of Cyrus, the Persian prince, against his elder brother Artaxerxes II. In this expedition 10,000 Greek mercenaries took part. When Cyrus fell in the battle of Cunaxa (401 B.C.) and the Greek leaders were put to death by Tissaphernes, Xenophon caused new leaders to be chosen, including himself. The main part of the *Anabasis* describes the retreat of the Greek mercenaries. Other strictly historical works by Xenophon are his essay upon Agesilaus, king of Sparta; an essay on *Athenian Revenues;* another on *Lacedaemonian Polity.*

The art of *rhetoric* was a development of the 5th century, the pioneer professional teachers of Oratory of whom we chiefly hear being Corax of Syracuse, his pupil Tisias and Gorgias of Leontini (whose style we can infer from the extant fragments). The Alexandrine canon recognized ten Attic orators: (1) Antiphon (*q.v.*, *c.* 480–411 B.C.) of whom we possess three Tetralogies, each consisting of four speeches, and three speeches in real cases. The interest of these speeches is twofold, first as examples of early forensic oratory, and secondly, all being concerned with cases of murder, as throwing light upon some intimate matters of Athenian social life which would otherwise be obscure; (2) Andocides (*q.v.*, born *c.* 440), under whose name four speeches are extant; (3) Lysias (*q.v.*), son of a Syracusan *μέτοικος*, of whom 34 speeches are extant. Simple and unaffected in style, they throw a flood of light on Athenian domestic and social life; (4) Isocrates (*q.v.*, 436–338 B.C., when "that dishonest victory at Chaeronea, fatal to liberty, Kill'd with report that old man eloquent"), of whom we have 21 orations. His interest is chiefly stylistic; he greatly influenced Cicero and through him modern prose style; (5) Isaeus (*q.v.*, *fl. c.* 360 B.C.), of whom we have 12 speeches (11 and 12 being incomplete). All the speeches, except No. 12, deal with the testamentary disposition of property and are of inestimable value for the knowledge of Attic private law; (6) Demosthenes (*q.v.*, b. 384 B.C.), under whose name we have 69 orations (not all, however, being orations, and not all genuine), the greatest oratory of antiquity (Quintil. x. 1.76). While his fame rests especially on the *Philippics, Olynthiacs, De Falsa Legatione,* and, above all, the *De Corona,* many of the other speeches are of high merit, while his private forensic speeches are extremely valuable for the information they afford, particularly in regard to the operations of commerce in ancient Greece; (7) Aeschines (*q.v.*, b. 390 B.C.), the great rival of Demosthenes, of whom we have three orations; (8) Lycurgus (*q.v.*, born *c.* 390 B.C.): one speech extant; (9) Hypereides (*q.v.*, born *c.* 390 B.C.), of whom we have fragments of six speeches, recovered since 1847 from papyri; (10) Deinarchus (*q.v.*, born *c.* 360 B.C.): three speeches extant.

Philosophic prose is represented by Plato (*q.v.*, b. 427 B.C. on the seventh of the month Thargelion, a day afterwards celebrated annually by the Platonic school—d. 348–7 [his will is quoted Diog. L. iii. 41]), under whose name we have 42 dialogues, besides some dozen letters. Some of the dialogues (in all of which, except the *Laws*, Socrates is an interlocutor) are certainly spurious, others of doubtful authenticity. All we need note here is that in Plato Greek prose attains its supreme perfection, a grace and ease and flexibility, capable of every emotion of which the soul is capable, such as perhaps no other prose in any language has attained. And this, coupled with sublimity and beauty of thought, with power to strengthen those hopes of men which aspire to immortality and seem to promise it, will ensure that such works as the *Apology*, the *Phaedrus*, the *Phaedo*, the *Republic*, will always remain among the most precious heritages of humanity.

Aristotle (*q.v.*, 384–332 B.C.) has left such an immensity of writing that here we can do no more than indicate his chief works under their appropriate headings: 1. Logic: *Topica, Analytica;* 2. Natural Science (for which his position as tutor to Alexander no doubt gave him special advantages): *Historia Animalium, De Partibus Animalium;* 3. Psychology and Metaphysics: *De Anima, Metaphysica;* 4. Ethics: *Nicomachean Ethics;* 5. Politics: *Politics, Respublica Atheniensium;* 6. Literature: *Poetics, Rhetoric.*

For convenience we may here include Aristotle's successor as head of the Peripatetic school, Theophrastus of Eresos (*c.* 372–287 B.C.), of whose writings we possess only: 1. *Historia Plantarum* (Περὶ φυτῶν ἱστορίας). 2. *De causis plantarum* (Περὶ φυτῶν αἰτιῶν). 3. *Characters* (χαρακτῆρες), and a few short pieces such as *De Signis* (Περὶ σημείων), which was apparently one of the sources used by Aratus for that part of the *Phaenomena* (733–1154) which is called Διοσημίαι, and some smaller fragments.

The Alexandrine Age, 323 B.C.–A.D. 100.—1. Before reviewing the Alexandrine *poets* individually, it is worth while to note certain characteristics of the Alexandrine poetry in general. In the first place it is no longer an original poetry like that of the Classical period, but imitative. One symptom of this is that quite different kinds of poetry are cultivated by the same poet. Next it is a learned poetry for the most part, and makes its appeal in the first place to a learned audience—being full of learned allusions, strange or archaic or dialectic words (γλῶσσαι) which had little meaning for the ordinary man. Again, as in all learned poetry, the mere knowledge of the work of an earlier poet impels the imitator in the search for novelty to sacrifice simplicity. What is meant can be well seen by comparing Homer's description of the abode of the gods in *Odyssey* vi. 42 *sqq.* with the successive imitations by Lucretius, Tennyson, Swinburne and again Tennyson. And the need for extreme elaboration tends to the cult of the short and highly polished poem rather than of the longer poem in which such uniformly high polish would make an excessive demand alike on the poet and on his reader. Again we note that the passion of love becomes now not a subsidiary, but a leading motive. Finally we notice a tendency—not perhaps unconnected with the growth of large cities—to take for theme the happiness of the simple peasant's life.

Callimachus (born *c.* 310 B.C.) is represented by six Hymns (five in hexameters, one in elegiacs), and by a large number of fragments in a variety of metres. Recent discoveries of papyri have added considerably to our knowledge of his work (especially the Αἴτια and Ἴαμβοι). He is the champion of the short poem (Athen. 72 A). On the other hand his contemporary and rival, Apollonius Rhodius, attempted in his *Argonautica* in four books (5,835 lines) to revive the long epic (*cf.* Callim. *Hymn* ii. 106, with Apollon. Rh. iii. 932 *seq.*). The didactic epic is revived by Aratus of Soli in Cilicia (born *c.* 315 B.C.) in his *Phaenomena* (1,154 lines), an astronomical poem, sometimes called Φαινόμενα καὶ Διοσημίαι because it falls into two well marked divisions—sometimes considered to be distinct poems—1–732 describing the relative position of the stars in the heavens and their risings and settings, 733–1154 dealing with weather signs in general. The poem, which was greatly praised in later times (Ovid, *Amor.* i.15.6) and was translated by Cicero, contains two passages of unusual beauty, the *Prooemium*, from which St. Paul quotes

(Acts xvii. 28: "As certain also of your own poets have said, 'For we are also his offspring' ") and the lines (96–136) which tell how Justice forsook the earth. Nicander (born *c.* 200 B.C.) continued the didactic epic in a series of poems of which two are extant: *Theriaca* (958 lines), on the bite of venomous beasts, and *Alexipharmaca* (630 lines), on antidotes. Neither of them has any poetic value.

We hear of a *Pleiad* of eminent tragedians of the time of Ptolemy Philadelphos, but we have no extant comedy or tragedy. Lycophron, one of the *Pleiad,* has left us, besides a few short fragments of tragedy, a poem of notorious difficulty called *Alexandra, i.e.,* Cassandra. Elegy is largely cultivated, the most famous elegist being Philitas (Philetas) of Cos (*c.* 300 B.C.), whose name is also associated with that of Callimachus by Propertius (iv.1.1).

The one important new poetic development of the period is the bucolic idyll associated with the names of Theocritus (born *c.* 305 B.C. in Syracuse, *cf. A.P.* ix. 434, Athen. 284 A) and the later Bion and Moschus (probably 2nd century B.C.). This type of poetry, a short poem in hexameters dealing with country life, and especially with herdsmen, goatherds and shepherds, became the model for the *Bucolics* of Virgil, and through him of all later pastoral poetry. The beautiful lament for Bion (= Mosch. *Id.*), the authenticity of which some now deny, was the model for Virg. *Bucol.* X., Milton's "Lycidas," and Shelley's "Adonais." The curious type of poetry called a mime, which has apparently some affinity with the idyll, is now represented by the eight mimes of Herondas (discovered in Egypt, 1890). The papyrus ms. obtained from the Fayum is in the possession of the British Museum.

2. The *prose literature* of the Alexandrine age is, for the most part, a learned literature. All branches of learning were cultivated with assiduity. The work of the Alexandrines in the department of literary criticism is discussed in a later part of this article. Their work in science—particularly mathematics and astronomy—hardly concerns us here. But a word must be said of three writers of this time who are of more general interest. Polybius (*q.v., c.* 201–120 B.C.) of Megalopolis in Arcadia, composed his *Histories* (Ἱστορίαι) in 40 books, of which only the first five are extant in their entirety, but we know the plan of the whole work. Polybius has none of the graces of style, his virtues being those of accuracy in detail and sound judgment. Strabo (*q.v., c.* 63 B.C.–A.D. 19) of Amaseia in Pontus, wrote a historical work (Ὑπομνήματα ἱστορικά) in 43 books, which dealt cursorily with the period before Polybius, and in detail with the period after Polybius (Suid. *s.* Πολύβιος): of this only fragments are preserved (*Frag. Histor. Gr.* iii. 490 *sqq.*). But his *Geography* (Γεωγραφικά), is preserved almost entire. Quite apart from its value as a contribution to the study of geography, his work is of extraordinary interest to the general student from the multitude of incidental information which it gives with regard to the various peoples mentioned in the course of the treatise. Plutarch (*q.v., c.* A.D. 46–120) of Chaeroneia in Boeotia, was a many sided polymath, most of whose works are fortunately extant. They fall into two groups, the *Parallel Lives* (probably mostly the work of his later life) and the series of popular essays called collectively *Moralia* (Ἠθικά). The *Parallel Lives* (Βίοι Παράλληλοι) consist of a series of biographies (46 extant) of eminent historical characters, a distinguished Greek being coupled with a distinguished Roman, to whom he seemed, in point of career, to bear some resemblance, each couple of biographies being followed by a *Comparison* (Σύγκρισις), in which the two are compared. The order of the biographies as given in the mss. is not that of our ordinary editions, which is based upon the Aldine edition and is without ms. authority, but partly follows chronological order. This arrangement, however, is not Plutarch's: thus, *e.g.,* we know from Plutarch himself (*Theos.* 1) that the *Lives* of Lycurgus and Numa were written before those of Theseus and Romulus. The *Moralia* is an immense collection (7 vols. in Teubner ed.) of essays on the widest variety of topics, ethical (these in the majority—hence the general title), historical, scientific. Though not profound, Plutarch is generally interesting, and the incidental allusions are often of the greatest value.

ROMAN LITERATURE

The story of Roman literature is a comparatively short one. Its whole lifetime is not equal to that single epoch of Greek literature which we call the Alexandrine age. Again, while the literature of Greece exhibits a completely independent development, Roman literature is at every point based upon Greek models. A consequence of this is that, while Greek literature shows a logical development, that of Rome develops more or less fortuitously. While, then, Greek literature is best presented in the order of evolution of the several literary types, there is no such reason for adopting the same method in summarizing the content of Roman literature, and the most convenient method of presentation is the chronological.

Roman literature may be said to begin about the middle of the 3rd century B.C., and it is conveniently divided into three periods: (1) the Republican age, 250–27 B.C.; (2) the Augustan age, 27 B.C.–A.D. 14; (3) the Imperial age, A.D. 14–524.

The Republican Age.—An account of the origins of Roman literature and of its representatives will be found under LATIN LITERATURE: here, where our object is merely to present a conspectus of the extant literature, the earliest period from which nothing but detached fragments survive, may be dismissed with a reference to the articles on Livius Andronicus (*c.* 284–204 B.C.), C. Naevius from Campania (d. Utica 201 B.C.), Q. Ennius (239–169 B.C.), M. Pacuvius (b. 220 B.C.) and L. Accius (b. 170 B.C.).

Far more important from our point of view are two poets who wrote comedies only. T. Maccius Plautus (*q.v.*) of Sarsina, in Umbria (*c.* 251–184 B.C.), is represented by 21 extant comedies—the so-called *fabulae Varronianae* (Aul. Gell. iii. 3. 3). They are all translated more or less closely from the Greek (*cf. Trin.* prol. 18 *Huic Graece nomen est Thensauro fabulae: Philemo scripsit: Plautus vortit barbare, Nomen Trinummo fecit,* and *Asin.* prol. 10).

P. Terentius Afer (*c.* 190–159 B.C.) of Carthage became the slave of Terentius Lucanus, whose name he took on manumission. Six of his comedies are extant. His chief model was Menander: *cf.* Caesar's lines *ap.* Sueton. *Vit. Ter.* "*Tu quoque tu in summis, O dimidiate Menander / Poneris et merito, puri sermonis amator: / Lenibus atque utinam scriptis adiuncta foret vis / Comica, ut aequato virtus polleret honore / Cum Graecis neque in hac despectus parte iaceres: / Unum hoc maceror et doleo tibi desse, Terenti.*" ("You too, even you, half-Menander, are ranked among the highest and rightly, lover of pure Latin; but I wish your smooth verse had comic power, that its virtue might be equally honoured with the Greek and you were not despised in this respect. Terence, I am hurt and pained to find you lack this one thing.") The merit and demerit of Terence, as here stated by Caesar, are precisely what strikes the modern student—the purity of his Latin and his lack of force. In the economy of his comedies, we note an innovation in that the prologue no longer has the function of introducing the play, but serves—much like the Parabasis in Aristophanes—as a vehicle of criticism (*cf., e.g., Adelph.* prol. 15 *seq.; Heaut.* prol. 22).

The earliest work in Latin prose which is extant entire is the *De Agri Cultura* of M. Porcius Cato (*q.v.,* 234–149 B.C.), a mere compendium of precepts on agriculture. His *Res Rusticae* (three books) is also the only complete work extant of M. Terentius Varro (*q.v.,* 116–27 B.C.), the most learned Roman of his time, who in his long life produced an extraordinary variety of works. His agricultural treatise is an immense advance on that of Cato in point of style. Of Varro's work *De Lingua Latina* in 25 books, only 5–10 are extant.

In the hands of Varro's younger contemporary, M. Tullius Cicero (*q.v.,* 106–43 B.C.), Latin prose style attains its highest perfection. Cicero's literary activity is amazing. Apart from his speeches (of which 58 are extant), we have several treatises on rhetoric, a great number of works on philosophy—largely written in the last two or three years of his life and particularly after the death of his daughter Tullia, and finally his correspondence: letters (1) *Ad Familiares* (16 books, 62–43 B.C.), (2) *Ad Quintum Fratrem* (3 books, 60–54 B.C.), (3) *Ad Atticum* (16 books, 68–44 B.C.), (4) *Ad M. Brutum* (2 books. 43 B.C.). The letters, written

as they are in a completely intimate and informal manner, constitute an extraordinarily important commentary on the events of his time and, revised in relation to those events, form a very interesting psychological study. G. Julius Caesar (*q.v.*, 102?–44 B.C.) wrote a treatise, *De Analogia* (two books), which one would have liked to see, and a tragedy *Oedipus*, which one would have liked to see still more. We possess, however, his *Commentarii de bello Gallico*, seven books, covering the years 58–52 B.C., and *Commentarii de bello civili*, three books, covering the years 49–48 B.C. The *Bellum Alexandrinum* is probably by A. Hirtius, who also added an eighth book to the *Bellum Gallicum*. The authors of the *B Hispaniense* and *B. Africanum* are unknown. G. Sallustius Crispus (86–34 B.C.) of Amiternum, wrote the *De Catilinae coniuratione* and the *Bellum Iugurthinum*, both extant, and *Historiae*, covering the years 78–67 B.C., of which we have some fragments.

Poetry in this period is represented by two names of the first rank. T. Lucretius Carus (*q.v.*, *c.* 99–*c.* 55 B.C.) expounds the philosophy of Epicurus in his *De Rerum Natura* (six books), the title being a translation of Περὶ Φύσεως, the title of poems by Xenophanes, Parmenides, Empedocles. He had a high reputation in antiquity. Virgil, who was greatly influenced by him and refers to him (without naming him) in a famous passage of the *Georgics* ii. 490, *Felix qui potuit rerum cognoscere causas Atque metus omnes et inexorabile fatum Subiecit pedibus strepitumque Acherontis avari*, is preferred to him by Quintilian (X. 1.86 *seq.*), on grounds which merely concern the student of oratory, and this preference has been supported by the general judgment, but not a few good judges would reverse the verdict. The strictly philosophical passages no longer appeal, but in the more popular passages, such as the Prooemium (i. 1–43), the eulogy of Epicurus (iii. 1–30), on the folly of fearing death (iii. 892–910), his passionate earnestness (*docti furor arduus Lucreti*, Stat. *Silv.* ii. 7.76), coupled with genuine poetic imagination and a real gift for poetic expression, affects the modern reader perhaps more than anything in Virgil. G. Valerius Catullus (*q.v.*, b. at Verona [Catull. lxvii. 34. Mart. xiv. 195, Ov., *Am.* iii. 15.7] 84–d. *c.* 54 B.C.), the greatest of Roman lyric poets, is represented by 116 poems in a variety of metres, hendecasyllables, iambic, trimeters (including scazons), sapphics, priapean, phalaecean, asclepiadean, hexameters, elegiacs, iambic tetrameter catalectic, galliambic (lxiii). Most of his poetry shows strong marks of Greek influence, and several poems are translations from the Greek: *e.g.*, li. (from Sappho), lxvi. (from the lost *Hair of Berenice* of Callimachus). His hexameters and elegiacs—though sometimes extremely effective, as in his lines at his brother's grave (ci.)—show much less grace and ease than his hendecasyllabic and priapean poems. Apart from technique he has the two chief gifts of the lyric poet—depth of feeling ("Tenderest of Roman poets nineteen hundred years ago"—Tennyson) and simplicity.

The Augustan Age, 27 B.C.–A.D. 14.—P. Vergilius Maro (70–19 B.C., *see* VIRGIL), generally regarded as the greatest of Roman poets, is represented by (1) *Bucolica* (*Eclogae*) ten poems in which Theocritus is imitated or even translated. Of these, only ii., iii., v., vii. and viii. are strictly pastoral, the pastoral setting in others being merely a framework, while in iv. (the so-called Messianic Eclogue) there is nothing of the pastoral at all; (2) *Georgica*, in four books (i. Agriculture, ii. Tree culture, iii. Cattle-rearing, iv. Bee-keeping). The *Georgics* contain some of Virgil's best poetry, *e.g.*, the praise of Italy, ii. 136–176; the eulogy of country life, ii. 458–540; the story of Orpheus and Eurydice, iv. 453–527; (3) *Aeneis*, in 12 books, the great national epic of Rome which, after ten years' work, was still unfinished (witness the "pathetic half-lines," the occasionally uncompleted hexameters) at his death, and was published by L. Varius against the expressed wishes of the poet. Virgil was a slow and careful writer (Quintil. x. 3.8, *cf.* Donat., *Vita Verg.* ix., Aul. Gell. xvii. 10.2). This very care and elaboration probably rather militates against the essentially epic virtues, and it is not so much as a whole that the poem appeals, at any rate to the modern world, as in certain supreme passages in which the poet rises above his immediate theme and which are really in the nature of digressions. Q. Horatius Flaccus (65–8 B.C., *see* HORACE), born at Venusia, was the son of a freedman (*cf.* Hor. *Sat.* i. 6.6; 45, 86). After the battle of Philippi (44 B.C.) he returned to Rome where presently he became a member of the circle of Maecenas. His extant work is of two quite different classes—lyrical (*Odes, Epodes, Carmen Saeculare*) and poems in hexameters (*Satires, Epistles, De Arte Poetica*). The *Satires* (*saturae* or *Sermones*) in two books, written between 41 and 30 B.C., deal lightly with the foibles and follies of social life, and the *Epistles*, 20–13 B.C., in two books, are very much in the same style as the *Satires*, with a greater preponderance of literary themes, which is emphasized in the epistle which bears a separate title: *On the Art of Poetry*. It is upon his lyrical poems that the fame of Horace as a poet really rests (Quintil. x. 1.96), and his success is due, not to any rare and high gift of poetic inspiration, but to his capacity for expressing with unsurpassed felicity, the common thoughts which touch most nearly the common heart of humanity. Albius Tibullus (*q.v.* d. 19 B.C. while still young) belonged to the circle of M. Valerius Messalla Corvinus, and was on friendly terms with Horace, who addressed to him *Carm.* i. 33 and *Ep.* i. 4, and Ovid (*cf.* Ov. *Tr.* iv. 10.51, and the beautiful elegy on Tibullus, Ov. *Amor* iii. 9). We possess four books of elegies under his name, but Bk. iii. is by "Lygdamus," a pseudonym for some undetermined poet; iv. 1 (panegyric on Messalla) is by some unknown author, while iv. 7–12 are by Sulpicia, a poetess of the time of Tibullus. To call him "polished and elegant" as Quintilian does (x. 1.93) hardly does justice to his tender grace.

Sextus Aurelius Propertius (*q.v.*, born *c.* 49 B.C. in Umbria, probably at Asisium [Assisi], where the name Propertius occurs in inscriptions) is represented by four books of elegies. Propertius has an irregular strength which is in marked contrast to the equable polish of Tibullus, and in the matter of form his pentameters have an elasticity and freedom which make the elegiac distich in his hands almost a new metre. Bk. iv. 11—the concluding elegy in our collection—is an excellent example of his mature style. P. Ovidius Naso (b. Sulmo 43 B.C.—died *c.* A.D. 18, *see* OVID) has left us a great variety of work. His undoubted poetic qualities are rather obscured by the amazing polish and facility of his versification. There remain but two poets of the Augustan age who need be mentioned here, both writers of didactic epic. Grattius, a contemporary of Ovid (Ov. *Ep. ex. Pont.* iv. 16.34), wrote the *Cynegetica*, a treatise on hunting after the Greek model, of which 541 lines are extant. Manilius, of whom nothing is known except what can be inferred from his poem—he must have written after A.D. 9, because in i. 898 he refers to the defeat in that year of Varus in the Teutoburg forest—wrote *Astronomica* (in five books), which is extant.

The prose writers of the Augustan age include only one name of first importance. T. Livius (59 B.C.–A.D. 17, *see* LIVY), was born at Patavium (Padua, *cf.* Mart. i. 61.3). In Rome he enjoyed the friendship of Augustus in spite of his admiration of Pompey (Tac. *Ann.* iv. 34). We hear of philosophical works and semi-philosophical dialogues written by him (Senec. *Ep.* 100.9), but his fame rests on his history of Rome (*Historiae ab urbe condita*) down to his own day (it was actually carried as far as 9 B.C.). The work was in 142 books, of which there are extant 35, viz., i.–x. (down to 293 B.C.), xxi.–xlv. (218–167 B.C.). The lost books are represented by *Periochae* (summaries of contents) composed *c.* 4th century A.D., which we possess for all except 136 and 137. An Oxyrhynchus papyrus preserves some excerpts from Bks. 37–40; 48–55. Livy, deficient as he was in technical equipment, is not exactly a scientific historian, but he is at least an honest one. In style he is nearer Cicero (*cf.* Quintil. x. 1.39) than Sallust. His language (despite Asinius Pollio's reproach of *Patavinitas*, Quintil. i. 5.56; viii. 1.3, the reference of which is obscure), with its somewhat poetical colouring, is splendidly adapted to his task (Quintil. i. 1.101). Other minor prose writers are Pompeius Trogus, L. Annaeus Seneca of Corduba (Cordova), and Vitruvius Pollio (*qq.v.*).

The Imperial Age.—Under Tiberius in A.D. 30, C. Velleius Paterculus wrote for M. Vicinius (consul in that year) his *Historia Romana*, a sketch of Roman history in two (extant) books. A contemporary writer of first importance, L. Annaeus Seneca (A.D. 3–65), son of the elder Seneca, has left us nine tragedies imitated from the Greek, and numerous prose philosophical

writings. M. Annaeus Lucanus (A.D. 39–65), nephew of the foregoing, is represented by an epic in ten books *De Bello Civili*, on the civil war between Pompey and Caesar. More rhetorical than poetical, Lucan has some memorable lines. Aulus Persius Flaccus (A.D. 34–62), is the author of six satires, mainly on the literary life of his time and on quasi-philosophical subjects. T. Calpurnius Siculus, in the reign of Nero, has left us seven eclogues full of adulation of Nero; the anonymous poem *De Laude Pisonis* is also now attributed to him. L. Iunius Moderatus Columella, contemporary with Seneca, is the author of 12 books *De Re Rustica* in prose except the tenth book which is in hexameters. Next we have a group of four poets: P. Papinius Statius (b. between A.D. 40 and 45, died *c.* 98) author of two epics—*Thebais* and *Achilleis*—and a collection of poems in various metres with the general title *Silvae*. Valerius Flaccus in the time of Vespasian, to whom his poem is dedicated, wrote the *Argonautica* in eight books. The matter is mainly taken from the *Argonautica* of Apollonius Rhodius and the style is a rhetorical imitation of Virgil. *T. Catius Silius Italicus* (d. 101) in the reigns of Nero, Vitellius and Vespasian, wrote an epic *Punica* (17 books). His poem, the matter of which is mainly taken from Livy, is highly rhetorical and has little poetical merit. A much more brilliant poet is M. Valerius Martialis (born *c.* A.D. 40, d. shortly after 100), represented by 14 books of epigrams, some being of remarkable beauty.

C. Plinius Secundus (*c.* A.D. 23–79) in 77 presented Titus with his *Naturalis Historia* (in 36 books). Quite devoid of style and of no independent authority, the work is of considerable importance as preserving information from authorities now lost. M. Fabius Quintilianus (*c.* A.D. 35–95) is the author of the *Institutio Oratoria* in 12 books, book X. containing a sort of comparative sketch of Greek and Roman literary history, which includes very happy critiques of the leading Greek and Roman writers. The greatest prose writer of the Imperial age is C. Cornelius Tacitus (*c.* A.D. 54–*c.* 118); we have his *Dialogus de Oratoribus, Agricola* (A.D. 98) *Germania* (about the same date), *Histories* (A.D. 69–96), *Annals* (probably written after A.D. 116). C. Plinius Caecilius Secundus (61–*c.* 114), nephew of the elder Pliny, is represented by nine books of letters, and in addition by the historically very important *Panegyricus* on Trajan and the correspondence with Trajan (including the extraordinarily important letters 96 and 97, dealing with the trial of the early Christians). C. Suetonius Tranquillus, who, under Hadrian, held the office of imperial secretary (*ab epistulis*), wrote the lives of the emperors (*De Vita Caesarum*) from Caesar to Domitian. We have also his treatise *De Grammaticis et de Rhetoribus*, originally part of a larger work, *De Viris Illustribus*, of which the extant *Vitae* of Terence, Horace, Lucan, Passienus Crispus, and the elder Pliny are fragments. D. Iunius Iuvenalis (b. Aquinum, probably A.D. 67) has left 15 satires written under Trajan and Hadrian. Juvenal is a master of vivid phrase: *e.g.*, his account of street dangers in *Sat.* iii. 264 *sqq.* So his single lines are memorable: *"facit indignatio versum"* (i. 79), *"mens sana in corpore sano"* (X. 356), *"maxima debetur puero reverentia"* (xiv. 47). We must dismiss the remaining authors summarily—with again a reference to their separate biographical articles and the article LATIN LITERATURE: M. Cornelius Fronto (2nd century A.D.); Aulus Gellius (born *c.* 130); L. Apuleius (b. at Madaura, in Africa, A.D. 114); the *Pervigilium Veneris*, by an author unknown; Ammianus Marcellinus (born *c.* 332); Decimus Magnus Ausonius (born at Bordeaux *c.* 300); Claudius Claudianus (born at Alexandria, died 404); Aurelius Prudentius Clemens, the first great Christian poet; C. Lollius Apollinaris Sidonius (*c.* 430–480), and lastly, Boethius (born *c.* 480, executed 524).

HISTORY OF SCHOLARSHIP

Pre-Alexandrine.—The history of classical scholarship goes back to a date so early that it is hardly possible to fix a superior limit. As soon as a philosopher began to criticize a literary work (*e.g.*, Xenophanes on Homer and Hesiod), so soon scholarship in the widest sense may be said to have begun. Philosophic speculation soon raised the question of the relation of the name to the thing named, or, in other words, directed attention to the true or inner meaning of words, the ἐτυμολογία, as opposed to the conventional meaning, and thus founded the science of etymology. Directly connected with this was the question of the right use of language, ὀρθοέπεια, with which the name of Protagoras (born *c.* 485 B.C.) was especially connected (Plato, *Phaedr.* 267 C.). This again naturally led to a consideration of the function of words in a sentence and thus to the evolution of a grammatical terminology. Plato already distinguished ὄνομα and ῥῆμα, not so much as noun and verb, but as subject and predicate (*cf.* Plato *Sophist.* 261; "There are two sorts of intimation of being given by the voice. . . . That which indicates action we call a verb . . . and the other, which is an articulate mark set on those who do the actions, we call a noun" *cf. Cratyl.* 425 A., Aristoph. *Nub.* 681 *sqq.*) Aristotle distinguished ὄνομα, ῥῆμα, ἄρθρον (*Poet.* xxi.7), σύνδεσμος (*Rhet.* iii., 5.2, etc.)—noun, verb, article, conjunction.

Alexandrine Period, 300–1 B.C.—Alexandria (for description *cf.* Strabo 793 *sqq.*) was founded by Alexander the Great in 331 B.C. After his death it became the capital of Egypt and the seat of the Ptolemaic dynasty. Under Ptolemy Soter (323–285 B.C.) and Ptolemy Philadelphus (285–247 B.C.) the two libraries and the museum of Alexandria became the greatest centre of literature and learning in the world.

The first librarian was Zenodotus of Ephesus (*c.* 325–260 B.C.). As librarian he classified the epic and lyric poets, the tragedians being classified by Alexander Aetolus, the comedians by Lycophron. As a scholar he made a critical recension of the *Iliad* and the *Odyssey*, founded on numerous mss., and compiled a Homeric glossary (Ὁμηρικαὶ Γλῶσσαι). He seems also to have dealt with the text of Hesiod, Anacreon and Pindar. As a critical scholar he seems to have erred on the side of too great subjectivity.

The poet Callimachus, who did much in the way of making catalogues (πίνακες), is often said to have succeeded Zenodotus as librarian, but there is no evidence for the statement (*cf. Callimachus*, Loeb ed. p. 6 *sqq.*). The next librarian of whom we hear is Eratosthenes of Cyrene (born *c.* 275 B.C.), who became librarian *c.* 235. A man of many-sided learning (hence called by his admirers *pentathlos*, while his detractors called him *Beta*, implying that he was second-best in all departments, but first in none), he wrote on geography, mathematics, astronomy, chronology. We are here concerned only with his work in classical scholarship, in which his chief production was a treatise on Old Attic Comedy (περὶ τῆς ἀρχαίας κωμῳδίας). His successor in the librarianship was Aristophanes of Byzantium, who became librarian in 195 B.C. He edited Homer, Pindar, Euripides, Aristophanes. He also elaborated a system of critical signs (obelus, sigma, antisigma) and accentuation, divided the strophes of the lyric poets into κῶλα ("limbs") and made an epitome of Aristotle's *Natural History* (ed. Lambros 1885). His successor, Aristarchus of Samothrace (*c.* 217–145 B.C.), enjoyed still greater fame and became for later antiquity the type of the philologist (Cic. *Ad. Att.* i 14.3). He published two editions of Homer, in which he followed the admirable principle, Ὅμηρον ἐξ Ὁμήρου σαφηνίζειν (explaining Homer by Homer), edited Hesiod, and concerned himself also with the text of the lyric poets, the tragedians, Herodotus, and Aristophanes, writing both continuous commentaries (ὑπομνήματα) and treatises on special questions (συγγράμματα). Aristarchus was the first to recognize the eight parts of speech (Quintil. i. 4.20) ὄνομα (noun), ῥῆμα (verb), ἀντωνυμία (pronoun), ἐπίρρημα (adverb), μετοχή (participle), ἄρθρον (article), σύνδεσμος (conjunction), πρόθεσις (preposition).

His pupil, Dionysius Thrax (*c.* 170–90 B.C.), wrote a Greek grammar, Τέχνη Γραμματική, which retained its vogue down to the Renaissance and has been the ultimate model of all modern grammars (ed. Uhlig, Leipzig, 1884). Didymus, on account of his industry surnamed χαλέντερος (copper-guts), wrote on Homer, Hesiod, Pindar, Bacchylides, the comedians, the Attic orators, and Thucydides.

Post-Alexandrine Period, 1 B.C.–1350.—Dionysius of Halicarnassus (who lived at Rome from 30 B.C. onwards) wrote a number of valuable works on literary criticism: *Letters to Ammaeus I. and II., De Compositione Verborum, De Oratoribus Antiquis, Letter to Pompeius*, etc. A very valuable treatise *On the*

Sublime (Περὶ ὕψους) is extant, probably of the 1st century A.D. Apollonius Dyscolus (*c.* 130) wrote a valuable treatise on syntax in four (extant) books. The most valuable feature of the scholarship of this period is a series of works on lexicography and kindred subjects by Moeris, Phrynichus, Harpocration, Pollux, Hesychius, Stephanus, Suidas, Photius, and the 12th century *Etymologicum Magnum*. Mention should be made of the *Deipnosophistae* of Athenaeus (2nd century) which preserves much curious information and is the source of most of the extant fragments of the Greek comic poets. Libanius (*c.* 314–393) is the author of a Life of Demosthenes and of Arguments to his speeches. With him we must close the tale of classical scholarship for nearly 1,000 years.

The Revival of Learning or the Italian Period 1350–1527.—A general account of the Renaissance is beyond the scope of this article and we can merely mention some of the leading names. Francesco Petrarca (1304–74) and Giovanni Boccaccio (1313–75) have an interest only as pioneers, being interested in Greek, but not themselves expert Greek scholars. Manuel Chrysoloras (1350–1415), a Greek immigrant, taught Greek in Florence (1396–1400). It was at the instigation of another Greek, Gemistus Plethon (1355–1452), that Cosmo de'Medici founded an academy for the study of Plato. His pupil, Joannes Bessarion (1403–72), a native of Trebizond, came to Italy in 1439 with the Greek emperor in an endeavour to unite the Greek and Roman churches. Thereafter he joined the Roman Church, becoming presently bishop of Frascati. He died at Ravenna in 1472, bequeathing his collection of mss. to Venice (St. Mark's Library). Theodorus Gaza (*c.* 1400–*c.* 1478), of Thessalonica, taught Greek for a time at Ferrara, afterwards in Rome and Naples. His Greek grammar was printed by Aldus Manutius at Venice in 1495, and he was also the author of translations of Aristotle, Aelian, Theophrastus *De Plantis*, and of Dionysius, *De Comp. Verborum*. Demetrius Chalcondylas (1428–1511) edited Homer (*ed. princeps*, 1488), Isocrates, Suidas. Laurentius Valla (1407–57) translated Homer, Herodotus, Thucydides. But the greatest philologist of the Renaissance was Petrus Victorius (1499–1584), who edited Sophocles, Isaeus, Aristotle's *Rhetoric, Poetics, Ethics, Politics*, Cicero, Terence, Sallust, Varro's *De Re Rustica*. Lastly, among famous collectors of mss. may be mentioned Poggio Bracciolini (1380–1459), who discovered a great number of Latin mss., and Giovanni Aurispa (*c.* 1370–1459), who, in 1423, brought to Venice 238 mss. including *Venetus A.* of the *Iliad* and the *Codex Laurentianus* (10th century, now in Florence) of Aeschylus, Sophocles and Apollonius Rhodius.

The Greek grammar (Ἐρωτήματα) of Constantius Lascaris printed at Milan by Paravisinus in 1476, was the first book to be printed wholly in Greek.

Later Periods.—*The French Period*, 1530–1700, is characterized by an interest more in the content than the form of the classical authors. Leading names are Budaeus (1457–1540), Robert (1503–59) and Henri Etienne (1528–98); and Adrianus Turnebus (1512–65), Isaac Casaubon (1559–1614), Joseph Justus Scaliger (1540–1609) and Charles du Fresne, Sieur du Cange (1610–88) (*qq.v.*).

The English and Dutch Period (18th century) is a period of comprehensive scholarship—of historical and literary as well as verbal criticism. The leading English scholars are Richard Bentley (1662–1742) and Richard Porson (1759–1808) (*qq.v.*), while in the Netherlands the chief names are Ezechiel Spanheim (1629–1710), the two Burmanns (the elder 1668–1741, the younger 1714–78) (*qq.v.*), Hemsterhuis (1685–1766) (*q.v.*), Valckenaer (1715–85), Wyttenbach (1746–1820) (*q.v.*).

The German Period is inaugurated by F. A. Wolf (1759–1824) (*q.v.*), whose *Prolegomena* to Homer was published in 1795. In this period we have two distinctive types of scholarship—(1) the historical and antiquarian and (2) the critical and grammatical. Leading representatives of the former are B. G. Niebuhr (1776–1831), August Boeckh (1785–1867), K. O. Müller (1797–1840), Otto Jahn (1813–69), Theodor Mommsen (1817–1903) (*qq.v.*) and of the latter G. Hermann (1772–1848), Immanuel Bekker (1785–1871) (*qq.v.*), and Lobeck (1781–1860).

Present Day.—It would perhaps be invidious to mention the names of distinguished scholars either recently gone from us or still living, but a few words may be said of certain features which characterize classical scholarship of the present day.

The most notable development of modern times has been undoubtedly the increased interest in archaeology, in the widest sense, which has been witnessed in the last 100 years, and more particularly in the last half century. As this is written, it is almost exactly a century since the foundation of the Archaeological Institute in Rome (1829). The French schools in Athens and Rome were founded respectively in 1846 and 1873, those of the United States in 1882 and 1895, the British schools in 1883 and 1901. Everywhere, ancient sites have been and are being excavated—Troy, Delphi, Mycenae, Tiryns, Sparta, Olympia, Epidaurus, Dodona, Delos, Crete have yielded results beyond all expectation—while the recovery of papyri from Egypt has not merely restored to us a considerable body of ancient Greek literature, such as Aristotle's *Constitution of Athens* (1891), Herondas (1891), Bacchylides (1897)—to mention only some examples—but has thrown a valuable light on the true nature of New Testament Greek.

The study of one department of archaeology, namely that of anthropology, and in particular of primitive ritual and religion, has strongly influenced the study of classics. There was a time when the attention of scholars was perhaps too exclusively devoted to the literary aspects of the classical writers—to textual criticism and the study of form. As a natural consequence the labours of successive generations were confined to the great literary masterpieces of antiquity, while comparatively little study was given to writers of inferior genius who, nevertheless, preserve for us antiquarian and anthropological information of the first importance. Moreover, much that even in the best authors was either overlooked or misunderstood, has taken a new meaning in the light of the comparative study of the beliefs and institutions of primitive man. It is hardly too much to say that archaeological and anthropological discovery and speculation have been a fruitful and vivifying development of classical studies in recent years.

But the interest in "pure scholarship" which has long been a distinctive feature of the study of classics in this country is still fully maintained. The practice of composition in Greek and Latin, which for long occupied a leading place in our school and university education, appears to have somewhat retrograded, and the art of verse composition in particular seems to be falling into some neglect. On the other hand, there has been in the last 50 years an increasing interest in the art of translation from the classics, and an increasing demand for translations which should be at once accurate in point of scholarship and acceptable from the point of view of literary form. This has been the aim successfully pursued by many scholars writing independently, while it is the professed purpose of such a series as the Loeb in the United States and the Budé series in France.

Although the classics no longer enjoy their old monopoly in education, the study of the Greek and Latin writers seems to flourish as vigorously as it has done at any time, and at the present moment, so far as the evidence goes, the prospects of classical scholarship as an indispensable force in education appear to be singularly bright. *See* also Greek Literature; Latin Literature.

(A. W. Ma.)

CLASSIFICATION is the arrangement of things in classes according to the characteristics that they have in common. Sometimes similar objects are brought together in space, but classification may occur also when the only act of arrangement done by the classifier is the giving of a common name to things of the same kind. In a complex classificatory scheme the *infimae species*, or lowest classes, are subordinated to higher classes, and these again to others still higher until the *summum genus*, or most inclusive category of the system, is reached. It should be noticed, however, that in biology the terms "species" and "genus" are not used, as here, in a relative sense, but indicate classes of two fixed levels; *i.e.*, below orders but above varieties.

When, as often, the *summum genus* is given from the beginning, the problem of classification is the same as that of logical division.

Exhaustiveness and exclusiveness can be secured at each level by dichotomy; *i.e.*, by dividing each class into two subclasses, one of things that have a certain character and the other of things that do not. This method has advantages for certain purposes such as the construction of a flora, but it does not satisfy the demand that kinds which are co-ordinate should be placed on the same level in the classificatory scheme. It has often been said that a logical division should proceed throughout according to one principle, and this is true if it is taken to apply to the division of any one genus into species, for otherwise there can be no guarantee that the species will be mutually exclusive. There is no reason, however, why a librarian should not first divide his books into large groups according to size and then subdivide each group according to subject matter. In contexts such as this there may indeed be many different ways of classifying the same things, all in a sense artificial, but all equally correct for their special purposes. The situation is rather different in science, where we assume the existence of natural kinds.

Classification is important for science because it is a prerequisite of all attempts to discover order in the world. (*See* SCIENTIFIC METHOD.) It started already with the beginnings of speech; but the groupings expressed in ordinary language do not go much beyond the practical needs of the men who use it, and scientists must therefore make their own vocabulary, either by adaptation of what they find in ordinary speech or by constructing new words from old roots. The classifications which they produce in this way sometimes surprise the layman, as for example when they distinguish spiders from insects and place them with crabs in the phylum of arthropods. The reason is that they are especially interested in those groupings which help most in the presentation of knowledge as a system. In biology, for example, the modern phylogenetic classification of organisms according to common ancestry is clearly bound up with attempts to systematize and explain the information collected by natural historians. But the notion of natural kinds is to be found already at the very beginning of the study of nature. Men have a use for words such as "lead" only because they find certain recognizable features such as grayness, weight and fusibility occurring frequently together. If there were no such combinations of observable features to attract attention, there could be no natural science. For the laws that are formulated in science are generalizations about the properties of things belonging to such kinds. In short, there is no clear line of demarcation between the work of scientific classification and the practice of induction (*q.v.*). (W. C. K.)

CLAUBERG, JOHANN (1622–1665), German philosopher, was born at Solingen, Westphalia, and studied the Cartesian philosophy under John Raey at Leyden. He became (1649) professor of philosophy and theology at Herborn and subsequently at Duisburg, where he died. He was one of the earliest teachers of the new doctrines in Germany and an exact and methodical commentator on his master's writings. Clauberg's theory of the connection between the soul and the body is in some respects analogous to that of Malebranche; but he is not therefore to be regarded as a true forerunner of Occasionalism, as he uses "Occasion" for the stimulus which directly produces a mental phenomenon, without postulating the intervention of God (H. Müller, *J. Clauberg und seine Stellung im Cartesianismus*). His view of the relation of God to his creatures is held to foreshadow the pantheism of Spinoza. All creatures exist only through the continuous creative energy of the Divine Being, and are no more independent of his will than are our thoughts independent of us. Clauberg's chief works are: *De conjunctione animae et corporis humani; Exercitationes centum de cognitione Dei et nostri; Logica vetus et nova; Initiatio Philosophi, seu Dubitatio Cartesiana;* a commentary of Descartes's *Meditations;* and *Ars etymologica Teutonum.*

A collected ed. of his philosophical works was pub. at Amsterdam (1691), with life by H. C. Hennin; *see* also E. Zeller, *Geschichte der deutschen Philosophie seit Leibnitz* (1873).

CLAUDE LORRAINE, the name often given in English to CLAUDE GELLÉE or GELÉE (1600–1682), French landscape painter, call in French *Lorrain* or *Le Lorrain.* He was born at Chamagne, near Toul, Lorraine. At about the age of 12 he went to Freiburg im Breisgau and later to Rome to train as a pastry cook, and in this capacity became attached to Agostino Tassi, who had a reputation as a painter of seaports. At an unknown date he had instruction from a Flemish artist, Goffredo Wals, in Naples. In 1625 he made a roundabout journey to Nancy where he was employed for a year as assistant to Claude Deruet, the duke of Lorraine's painter, on work for the ceiling of the Carmelite church (now destroyed). In 1627 he returned to Rome and stayed there till his death (Nov. 23, 1682).

His fame as a landscape painter was established by the end of the 1630s and his numerous patrons, mostly from the Roman church aristocracy, included Pope Urban VIII. It is said that about 1634 Sébastien Bourdon copied one of Claude's landscapes in eight days. To guard against such copying and to record his most famous compositions, Claude made tinted outline drawings of most of his pictures in six paper books which he entitled the *Libro di verità* or *Liber veritatis* (*see* M. Davies, *National Gallery Catalogues: French School* [London, 1946]). This valuable record is at Chatsworth, Eng.; it was engraved in 1777 by Richard Earlom.

Claude's style is, in a manner of speaking, without history, for once he had found his idiom he did not stray outside it. He painted instinctively, not intellectually as did his contemporary Nicolas Poussin, and chose to paint only that which gave him abiding pleasure, namely the reach of golden sunlight on the country around Rome or on the waters of some mythical seaport.

Claude has been called the meeting point of the northern and southern landscape traditions. The northern tradition, that of Adam Elsheimer and Paul Bril, was the one in which Claude had been trained, for his master Tassi was a pupil of Bril. Entailing a dramatic approach to the subject, it depended on marked contrasts of light and dark, on huge tree masses dominating the scene. The southern tradition, represented by the Carracci and by Domenichino, consisted of an intellectual approach to nature which was conceived as a matter of orderly recession and balanced masses. Claude began in the northern naturalistic manner, and his early works (*e.g.*, "View of the Campo Vaccino," Louvre) show a meticulous attention to detail. He gradually emancipated himself from this and moved on to the southern or classical formula but he always kept the northern device of placing a dark tree or building in the foreground to deflect the eye to the source of light on the horizon.

In the 17th century pure landscape did not exist, so that all Claudes landscapes contain a story, either from the Bible or from Greek mythology or the modern romances of Tasso and Ariosto. His subjects have one thing in common: all are treated in an idyllic, as against a dramatic, manner, so that the protagonists do not obtrude themselves too much on the attention. An indifferent figure painter, Claude often delegated this part of his picture to a minor artist such as Jan Miel or Filippo Lauri. As he grew older, the purely anecdotal part of his pictures became reduced in scale and in importance, and at the end of his life nature assumed crushing proportions. He abandoned the more conventional seaport scenes for pure landscape, which took on an intense and visionary quality (*see* "Aeneas Hunting in Libya," 1672, Brussels).

Claude's technique can be studied in any painting of his mature period (*i.e., c.* 1640–60). Structurally he relies on the simple device of a horizon set off by a vertical tree or building in the foreground, all the objects in between being fused by a masterly representation of sun, heat and light. The perspective is established not by compositional lines but by gradations of tone which are themselves governed by light.

Claude rarely painted from nature but he sketched in the open air and worked up the finished pictures in his studio. Perhaps the most precious of Claude's drawings, which display great range and variety, are those rapid and delicate wash sketches which simply establish the relative positions of a tree and a hill. The finished pen drawings are more conventional and northern in style. The British Museum contains several volumes of drawings as do the Louvre and the Albertina, Vienna. Claude's paintings are to be found in all the major European collections, notably the National gallery, London, the Louvre, and the Doria palace, Rome.

CLAUDEL, PAUL (1868–1955), French poet, dramatist and diplomat, was born Aug. 6, 1868 at Villeneuve-sur-Fin. He was educated at the Lycée Louis-le-Grand, and entered the consular service in 1892. The early part of his diplomatic career was spent in the east as consul at Foochow, Shanghai and Tientsin. As first secretary at Peking he gained a valuable acquaintance with Chinese life and thought. In 1921 he was made French ambassador at Tokyo after a series of European appointments and three years in Rio de Janeiro.

He was appointed ambassador at Washington (1927), and at Brussels (1933). The worldly wisdom which he had acquired in the course of his official duties did much to stimulate and colour his poetry and helped to make his style among the weightiest and richest in French literature. Though trained in the school of the Symbolists, and especially of Rimbaud, Claudel breaks away from them in certain essential particulars. His fundamental inspiration is catholicism—but the catholicism is the fruit of his own meditation and is, as it were, re-created. The cosmic breadth of his views, his deep metaphysical interest and his fine treatment of

both the grandiose and the commonplace derive from his close study of Aeschylus (whose *Oresteia* he has translated) of Dante and of Holy Writ. He has created his own style, a plastic versification founded on a meticulous study of the rhythm of word and pause. Of his purely lyrical works, the following are the principal: *Cinq Grandes Odes* (1910); *Le Cantate* (1914); *Corona Benignitatis Dei* (1915); *Feuilles des Saints* (1925); but his reputation will most surely rest on his plays; those of outstanding merit are: *Tête d'or; La Ville; L'Échange; La Jeune Fille Violaine* (pub. in 1901 under the title *L'Arbre*)—in which the influence of the Symbolists is clearly perceptible; *L'Annonce faite à Marie* (1912) and the great trilogy in which he has attempted to reproduce the moral drama of post-revolutionary days: *L'Otage* (1911); *Le Pain Dur* (1918); *le Père Humilié* (1919). Many of Claudel's chief works have been translated into English, *e.g.*, *Connaissance de l'Est* (by T. Frances and W. R. Benét as "The East I Know"); and *L'Annonce faite à Marie* (by L. M. Still, 1916). Claudel died in Paris on Feb. 23, 1955.

CLAUDET, ANTOINE FRANÇOIS JEAN (1797–1867). French photographer, was born at Lyons on Aug. 12, 1797. Having acquired a share in L. J. M. Daguerre's invention, he was one of the first to practise daguerreotype portraiture in England, and he improved the sensitizing process by using chlorine in addition to iodine, thus gaining greater rapidity of action. In 1848 he produced the photographometer, an instrument designed to measure the intensity of photogenic rays; and in 1849 he brought out the focimeter, for securing a perfect focus in photographic portraiture. He was elected F.R.S. in 1853, and in 1858 he produced the stereomonoscope, in reply to a challenge from Sir David Brewster. He died in London on Dec. 27, 1867.

CLAUDIA NOVA, VIA, an ancient road of Italy, 47m. in length, connecting the Via (Claudia) Valeria with the Via Caecilia and Via Salaria at Foruli, near Amiternum and thus linking together the road systems of north and south Italy. It was built by the emperor Claudius in A.D. 47. Its course and remains, as well as the ancient towns and buildings along it, are described by R. Gardner in *Journal of Roman Studies*, iii. (1913) 205–232.

CLAUDIANUS, CLAUDIUS (Anglicized, CLAUDIAN), Latin epic poet during the reign of Arcadius and Honorius. He was an Egyptian by birth, probably an Alexandrian. In A.D. 395 he appears to have come to Rome, and made his debut as a Latin poet by a panegyric on the consulship of Olybrius and Probinus. (In Birt's edition a complete chronological list of Claudian's poems is given, and also in J. B. Bury's edition of Gibbon (iii. app. i. p. 485), where the dates given differ slightly from those in the present article.)

In 396 appeared the encomium on the third consulship of the emperor Honorius, and the epic on the downfall of Rufinus, the unworthy minister of Arcadius at Constantinople, which was engineered by Stilicho. Claudian's poem appears to have obtained his patronage, or perhaps that of his wife Serena (*Epist.* 2) In 398 appeared his panegyric on the fourth consulship of Honorius, his epithalamium on the marriage of Honorius to Stilicho's daughter, and his poem on the Gildonic War, celebrating the repression of a revolt in Africa. To these succeeded his piece on the consulship of Manlius Theodorus (399), the unfinished invective against the Byzantine prime minister Eutropius in the same year, the epics on Stilicho's first consulship and on his repulse of Alaric (400 and 403), and the panegyric on the sixth consulship of Honorius (404). From this time all trace of Claudian is lost, and he is generally supposed to have perished with his patron Stilicho in 408. It may be conjectured that he must have died in 404, as he could hardly otherwise have omitted to celebrate Stilicho's destruction of the barbarian host led by Radagaisus in the following year. On the other hand, he may have survived Stilicho, as in the dedication to the second book of his epic on the *Rape of Proserpine* (which Birt, however, assigns to 395–397), he speaks of his disuse of poetry. From Augustine's allusion to him in the *De civitate Dei*, it may be inferred that he was no longer living at the date of the composition of that work, between 415 and 428.

Besides Claudian's chief poems, his lively Fescennines on the emperor's marriage, his panegyric on Serena, and the *Gigantomachia*, a fragment of an unfinished Greek epic, may also be mentioned. Several poems expressing Christian sentiments are spurious. It is probable that he was nominally a Christian, like his patrons Stilicho and Ausonius, although at heart attached to the old religion. He was honoured by a bronze statue in the forum, and Pomponius Laetus discovered in the 15th century an inscription (*C.I.L.* vi. 1710) on the pedestal, which, formerly considered spurious, is now generally regarded as genuine.

The revival of Latin poetry at so late a date, and by a poet of foreign birth is remarkable, and it is no less surprising that Claudian should have won fame by official panegyrics. As remarked by Gibbon, "he was endowed with the rare and precious talent of raising the meanest, of adorning the most barren, and of diversifying the most similar topics." This gift is especially displayed in his poem on the downfall of Rufinus. In his celebration of Stilicho's victories Claudian found a subject more worthy of his powers, and some passages, such as the description of the flight of Alaric, and of Stilicho's arrival at Rome, rank among the brightest ornaments of Latin poetry. Yet on the whole he lacks creative power, and his talent is rather that of the rhetorician than the poet.

BIBLIOGRAPHY.—The editio princeps of Claudian was printed at Vicenza in 1482; the editions of J. M. Gesner (1759) and P. Burmann (1760) are still valuable for their notes. The first critical edition was that of L. Jeep (1876–79), now superseded by the exhaustive work of T. Birt, with bibliography, in *Monumenta Germaniae Historica* (x., 1892; smaller ed. founded on this by J. Koch, Teubner series, 1893). Edition with English translation by Platmauer (Loeb series, 1922). There is a separate edition with commentary and verse translation of *Il Ratto di Proserpina*, by L. Garces de Diez (1889); the satire *In Eutropium* is discussed by T. Birt in *Zwei politische Satiren des alten Rom* (1888). There is a complete English verse translation of little merit by A. Hawkins (1817). *See* the articles by Ramsay in Smith's *Classical Dictionary* and Vollmer in Pauly-Wissowa's *Realencyclopädie der classischen Altertumswissenschaft*, iii. 2 (1899); also J. H. E. Crees, *Claudian as an Historian* (1908), the "Cambridge Historical Essay" for 1906 (No. 17); T. Hodgkin, *Claudian, the last of the Roman Poets* (1875). H. Schroff, *Claudians Gedicht vom Gotenkrieg* (1927) with bibliography.

CLAUDIUS, the name of a famous Roman gens. The by-form *Clodius* was regularly used for certain Claudii in late republican times, but otherwise the two forms were used indifferently. The gens contained a patrician and a plebeian family; the chief representatives of the former were the Pulchri, of the latter the Marcelli (*see* MARCELLUS). The following members deserve particular mention:—

1. APPIUS SABINUS INREGILLENSIS, or REGILLENSIS, CLAUDIUS, so called from Regillum (or Regilli) in Sabine territory, founder of the Claudian gens. His original name was Attus or Attius Clausus. About 504 B.C. he settled in Rome, where he and his followers formed a tribe. In 495 he was consul, and his enforcement of the laws of debt was one of the chief causes of the "secession" of the plebs to the Sacred Mount. *See* Suetonius, *Tiberius*, i.; Livy ii. 16–29; Dion. Halic. v. 40, vi. 23, 24.

2. CLAUDIUS, APPIUS, surnamed CRASSUS, a Roman patrician, consul in 471 and 451 B.C., and in the same and following year one of the decemvirs. At first he was conspicuous for his aristocratic pride and bitter hatred of the plebeians. Twice they refused to fight under him, and fled before their enemies. He retaliated by decimating the army. He was banished, but soon returned, and again became consul. In the same year (451) he was made one of the decemvirs who had been appointed to draw up a code of written laws. He managed, by courting the people, to secure his re-election for the year 450, and the new decemvirs, under his leadership, began a reign of terror. Matters were brought to a crisis by the affair of Virginia, the daughter of Virginius, a plebeian centurion. Claudius, desiring to possess her, got a client to swear falsely that she was the child of his slave, and judgment was given in his favour. To save her, Virginius killed her with his own hand. An insurrection was the result, and the people seceded to the Sacred Mount. The decemvirs were finally compelled to resign and Appius Claudius died in prison, either by his own hand or by that of the executioner. For a discussion of the character of Appius Claudius, *see* Mommsen's appendix to vol. i.

of his *History of Rome*, also Livy iii. 32–58; Dion. Halic. x. 59, xi. 3.

3. CLAUDIUS, APPIUS, surnamed CAECUS, Roman patrician and author. In 312 B.C. he was elected censor without having been consul. During his censorship, which he retained for five years, in spite of the lex Aemilia which limited the tenure of that office to 18 months, he filled vacancies in the senate with men of low birth, in some cases even the sons of freedmen (Diod. Sic. xx. 36; Livy ix. 30; Suetonius, *Claudius*, 24). He abolished the old free birth, freehold basis of suffrage. He enrolled the freedmen and landless citizens both in the centuries and in the tribes, distributing them through all the tribes and thus giving them practical control of the elections. In 304, however, the landless and poorer freedmen were limited to the four urban tribes, and the effect of Claudius's arrangement was annulled. Appius Claudius transferred the charge of the public worship of Hercules in the Forum Boarium from the Potitian gens to a number of public slaves. He further invaded the exclusive rights of the patricians by directing his secretary to publish the *legis actiones* (methods of legal practice) and the list of *dies fasti* (or days on which legal business could be transacted). Lastly, he gained enduring fame by the construction of a road and an aqueduct, which—a thing unheard of before—he called by his own name (Livy, ix. 29; Frontinus, *De Aquis*, 115; Diod. Sic. xx. 36). In 307 he was elected consul for the first time. In 298 he was interrex; in 296, as consul, he led the army in Samnium (Livy, x. 19). During the next year he was praetor, and he was once dictator. In spite of his political reforms, he opposed the admission of the plebeians to the consulship and priestly offices; his probable aim was to strengthen the power of the magistrates and lessen that of the senate. He was already blind and too feeble to walk, when Cineas, the minister of Pyrrhus, visited him, but so vigorously did he oppose every concession that all the eloquence of Cineas was in vain, and the Romans forgot past misfortunes in the inspiration of Claudius's patriotism (Livy, x. 13; Justin, xviii., 2; Plutarch, *Pyrrhus*, 19). The story of his blindness, however, may be merely a method of accounting for his cognomen. Tradition regarded it as a punishment for his transference of the cult of Hercules from the Potitii.

His speech against peace with Pyrrhus was the first that was transmitted to writing, and thereby laid the foundation of prose composition. He was the author of a collection of aphorisms in verse mentioned by Cicero (of which a few fragments remain), and of a legal work entitled *De Usurpationibus*. It is very likely also that he was concerned in the drawing up of the *Legis Actiones* published by Flavius. He also interested himself in grammatical questions, distinguished the two sounds R and S in writing, and did away with the letter Z.

See Mommsen's appendix to his *Roman History* (vol. i.); treatises by W. Siebert (1863) and F. D. Gerlach (1872), dealing especially with the censorship of Claudius.

4. CLAUDIUS, PUBLIUS, surnamed PULCHER, son of (3). He was the first of the gens who bore this surname. In 249 he was consul and appointed to the command of the fleet in the first Punic War. Instead of continuing the siege of Lilybaeum, he decided to attack the Carthaginians in the harbour of Drepanum, and was completely defeated. The disaster was commonly attributed to Claudius's treatment of the sacred chickens, which refused to eat before the battle. "Let them drink then," said the consul, and ordered them to be thrown into the sea. Having been recalled and ordered to appoint a dictator, he nominated a subordinate official, but the nomination was at once overruled. Claudius himself was accused of high treason and heavily fined. He must have died before 246, probably by his own hand. *See* Livy, *Epit.*, 19; Polybius, i. 49; Cicero, *De Divinatione*, i. 16, ii. 8; Valerius Maximus, i. 4, viii. 1.

5. CLAUDIUS APPIUS, surnamed PULCHER, Roman statesman and author. He served under his brother-in-law Lucullus in Asia (72 B.C.) and was commissioned to deliver the ultimatum to Tigranes, which gave him the choice of war with Rome or the surrender of Mithradates. In 57 he was praetor, in 56 propraetor in Sardinia, and in 54 consul with L. Domitius Ahenobarbus. Pompey reconciled him to Cicero, whose return from exile he had opposed. In 53 he became governor of Cilicia. During this period he carried on a correspondence with Cicero, whose letters to him form the third book of the *Epistolae ad Familiares*. Claudius resented the appointment of Cicero as his successor, avoided meeting him, and issued orders after his arrival in the province. On his return to Rome Claudius was impeached by P. Cornelius Dolabella, and was obliged to make advances to Cicero, since it was necessary to obtain witnesses in his favour from his old province. He was acquitted, and a charge of bribery against him also proved unsuccessful. In 50 he was censor, and expelled many of the members of the senate. When Caesar marched on Rome he fled from Italy. He was appointed by Pompey to the command in Greece, and died in Euboea about 48, before the battle of Pharsalus. He wrote a work on augury, the first book of which he dedicated to Cicero. *See* Orelli, *Onomasticon Tullianum*.

BIBLIOGRAPHY.—A full account of all the Claudii will be found in Pauly-Wissowa's *Realencyclopädie der classischen Altertumswissenschaft*, iii. 2 (1899). *See* also L. A. Constans, *Un Correspondant de Cicéron, Ap. Claudius Pulcher* (1921).

CLAUDIUS (TIBERIUS CLAUDIUS DRUSUS NERO GERMANICUS), Roman emperor A.D. 41–54, son of Drusus and Antonia, nephew of the Emperor Tiberius, and grandson of Livia, the wife of Augustus, was born at Lugdunum (Lyons) on Aug. 1, 10 B.C. He was kept in the background by (Suet. *Claud.* 4) Augustus Tiberius, owing to his physical infirmities and apparent weakness of intellect, and lived in retirement; it was probably at this time that he became dependent on the company of freedmen. Under Caligula he became more prominent, holding the consulship (A.D. 37) and other public posts; though he was the emperor's butt, many people at Rome must have realized that he might succeed. On the murder of Caligula, Claudius, though not of the Julian gens, was made emperor by the praetorians, who were rewarded with a large donative, and were probably increased in number.

Claudius, though abnormal, was by no means the idiot that our hostile sources would suggest. Despite his pedantry, he had a certain shrewdness, and wished to govern well. In the earlier part of his reign he extended the boundaries of the empire; Mauretania was subdued and annexed in 43, and in the same year Claudius himself took part in the famous expedition to Britain, which gave the Romans a footing in the south of the island; in 44 Judea, which had been entrusted to King Agrippa (*q.v.*), was made once more a province, and in 46 the same fate overtook the client kingdom of Thrace.

In his dealings with the provincials Claudius, despite senatorial opposition, reverted to Julius Caesar's liberal policy. We possess part of his speech proposing that the chieftains of the Aedui should be admitted to the senate (*see* the paraphrase of it in Tacitus *Annals*), and his edict conferring citizenship on the Anauni (Hardy, *Roman Laws and Charters* Oxford, 1912). A large number of municipia and colonies in the provinces owe their origin to Claudius.

The reign of Claudius is marked by the development of the emperor's personal service. There was an extension of procuratorial government in the provinces (*e.g.*, Thrace, Mauretania, and Judea) and provincial procurators were granted jurisdiction equal to that of the emperor in all cases relating to the fiscus. A definite scale of salaries was also instituted. But even more notable was the increased power of the emperor's freedmen, who, while they remained his personal servants, became, in practice, powerful ministers, and received great rewards and honour. (*See*, besides authorities below, Statius, *Silv.* iii. and v.) The rule of the freedmen, who, though efficient, were arrogant and corrupt, was resented by the nobility, but the practice was continued under later emperors, though not to the same extent.

Another grievance was the increased importance of the emperor's private court. Under Augustus and Tiberius its use had been restricted to certain cases of *majestas*, but Claudius had a passion for acting as judge; vast numbers of cases were heard *in camera*, and the emperor's methods seem often to have been capricious.

His public works include a new harbour at Ostia, the draining of the Fucine Lake, and the construction of two aqueducts (*Aqua*

Claudia and *Anio Novus*). His revival of the censorship and extension of the poemerium may be quoted rather as examples of his antiquarianism than as practically important. In 47 he celebrated the Ludi Saeculares.

In the latter part of his reign his government degenerated and he fell entirely under the influence of his favourites and his womenkind.

He had married (as his third wife) Messalina, who, in 47, if we are to believe Tacitus, actually went through a form of marriage with Silius, unknown to Claudius. Narcissus brought about her execution, and, at the prompting of Pallas, the *a nationibus*, Claudius married his niece Agrippina, a marriage which shocked Roman sentiment. She induced him to set aside his own son Britannicus and to adopt as heir Nero, her son by a former marriage. Claudius died suddenly in 54, poisoned, according to Tacitus, by Agrippina. He was deified, but Seneca's satire, the *Apocolocyntosis*, expresses the relief felt at his death.

Claudius wrote several historical works "magis inepte quam ineleganter," including his own autobiography, but all, unfortunately, are lost.

BIBLIOGRAPHY.—Ancient: The *Annals* of Tacitus, Bks. xi., xii. Suetonius and Dio Cassius. *See* also Seneca, *Consolatio ad Polybium*, and *Apocolocyntosis* (ed. Ball, 1902, with introduction and translation); Josephus, *Ant. Jud.* Modern: H. CLAUDIUS, MARCUS AURELIUS, surnamed GOTHICUS, Roman emperor A.D. 268–270, belonged to an obscure Illyrian family. On account of his military ability he was placed in command of an army by Decius; and Valerian appointed him general on the Illyrian frontier, and ruler of the provinces of the lower Danube. During the reign of Gallienus, he was called to Italy to crush Aureolus, and on the death of the emperor (268) was chosen as his successor. Shortly after his accession he routed the Alamanni on the Lacus Benacus (some doubt is thrown upon this); in 269 a great victory over the Goths at Naïssus in Moesia gained him the title of Gothicus. In the following year he died of the plague at Sirmium. He enjoyed great popularity, and appears to have been a man of ability and character.

His life was written by Trebellius Pollio, one of the *Scriptores Historiae Augustae; see* also Zosimus i. 40–43; Homo, *De Claudio Gothico* (1900); Pauly-Wissowa, *Realencyklopädie*, ii. 2458 *et seq.* (Henze).

CLAUDIUS, MATTHIAS (1740–1815), German poet, otherwise known by the *nom de plume* of Asmus, was born on Aug. 15, 1740, at Rheinfeld, near Lübeck, and studied at Jena. From 1771 to 1775 he edited a newspaper called the *Wandsbecker Bote* (*Wandsbeck Messenger*), in which he published a large number of prose essays and poems. He died on Jan. 21, 1815. In his later days Claudius became strongly pietistic.

BIBLIOGRAPHY.—Claudius's collected works were published under the title of *Asmus omnia sua secum portans, oder Sämtliche Werke des Wandsbecker Boten* (8 vols., 1775–1812; 13th ed., by C. Redich, 2 vols., 1902). His biography has been written by Wilhelm Herbst (4th ed., 1878). *See* also M. Schneidereit, *M. Claudius, seine Weltanschauung und Lebensweisheit* (1898).

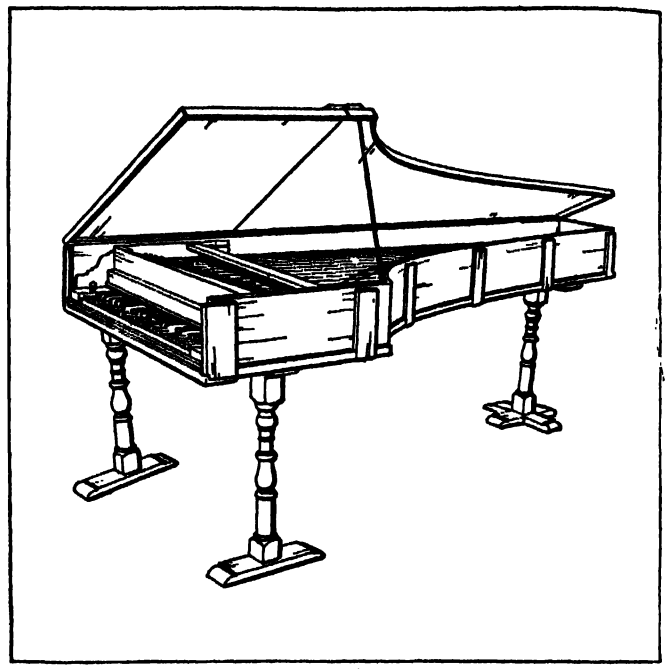
CLAUS, ÉMILE (1849–1924), Belgian painter, was born at Vive Saint-Éloi, Flanders, on Sept. 27, 1849. Receiving early training at the Antwerp Academy of Fine Arts, Claus began as a traditionalist. Soon, however, he came under the influence of certain French painters who had determined to break from the rut, and he completely changed his style, in spite of the fact that he had achieved a certain reputation and his work was remunerative. He started to paint in high lights by the juxtaposition of pure colours. He settled at Astène, in a house on the bank of the Lys, which he called *Zonneschijn*. There he began to paint that beautiful series of views of meadows, gardens, fields, streams and roads.

During the World War Claus resided in London, and from the windows of a house on the Victoria Embankment painted views of the Thames, showing the changing effects of the light and the weather. In 1917 he accompanied the Queen of the Belgians to La Panne, and visited the devastated regions. In 1920 he returned to Astène and worked there until his death, on June 6 1924. He was the recipient of numerous Belgian and foreign honours. He is represented in the Luxembourg, Paris, and in galleries in Venice, Brussels, Antwerp, Ghent and Liège.

CLAUSEL (more correctly CLAUZEL), **BERTRAND,** COUNT (1772–1842), marshal of France, was born at Mirepoix (Ariège) on Dec. 12, 1772, and served in the first campaign of the French Revolutionary Wars as one of the volunteers of 1791. In June 1795, having distinguished himself repeatedly in the war on the northern frontier (1792–93) and the fighting in the eastern Pyrenees (1793–94), Clausel was made a general of brigade. In this rank he served in Italy in 1798 and 1799, in the expedition to S. Domingo in 1802, in Naples in 1806. In 1808–09 he was with Marmont in Dalmatia, and at the close of 1809 he was appointed to a command in the army of Portugal under Massena.

Clausel took part in the Peninsular campaigns of 1810 and 1811, including the Torres Vedras campaign, and under Marmont he did excellent service in re-establishing the discipline, efficiency, and mobility of the army. In the Salamanca campaign (1812) the result of Clausel's work was shown in the marching powers of the French, and at the battle of Salamanca, Clausel, who had succeeded to the command on Marmont being wounded, and had himself received a severe wound, drew off his army with the greatest skill. Early in 1813 Clausel was made commander of the army of the north in Spain, but he was unable to avert the great disaster of Vittoria. Under the supreme command of Soult he served through the rest of the Peninsular War with unvarying distinction. During the Hundred Days he was in command of an army defending the Pyrenean frontier. After Waterloo he escaped to America, being condemned to death in absence. He took the first opportunity of returning to aid the Liberals in France (1820), sat in the chamber of deputies from 1827 to 1830, and after the revolution of 1830 was at once given a military command. At the head of the army of Algiers, Clausel made a successful campaign, but he was soon recalled by the home government, which desired to avoid complications in Algeria. At the same time he was made a marshal of France (Feb. 1831). For some four years thereafter he urged his Algerian policy upon the chamber of deputies, and finally in 1835 was reappointed commander-in-chief. But after several victories, including the taking of Mascara in 1835, the marshal met with a severe repulse at Constantine in 1836. A change of government in France was primarily responsible for the failure, but public opinion attributed it to Clausel, who was recalled in Feb. 1837. He thereupon retired from active service and lived in complete retirement up to his death at Secourrieu (Garonne) on April 21, 1842.

CLAUSEN, SIR GEORGE (1852–1944), English painter, born in London, the son of a decorative artist. He attended the design classes at the South Kensington schools from 1867–73. He then worked in the studio of Edwin Long, R.A., and subsequently in Paris under Bouguereau and Robert-Fleury. His "Girl at the Gate" was placed in the Tate gallery. He became R.A. in 1908 and was knighted in 1927. His series of lectures to the students of the Royal Academy schools was published as *Six Lectures on Painting* (1904), and *Aims and Ideals in Art* (1906). He died at Cold Ash near Newbury, England, on Nov. 23, 1944.



CLAUSEWITZ, KARL VON (1780–1831), Prussian general and military writer, was born at Burg, near Magdeburg, on June 1, 1780. His family, originally Polish, had settled in Germany at the end of the previous century. Entering the army in 1792, he first saw service in the Rhine campaigns of 1793–94, receiving his commission at the siege of Mainz. On his return to garrison duty he set to work so zealously to remedy the defects in his education caused by his father's poverty, that in 1801 he was admitted to the Berlin academy for young officers, then

directed by Scharnhorst. Scharnhorst, attracted by his pupil's industry and force of character, paid special attention to his training, and profoundly influenced the development of his mind. In 1803, on Scharnhorst's recommendation, Clausewitz was made "adjutant" (aide-de-camp) to Prince August, and he served in this capacity in the campaign of Jena (1806), being captured along with the prince by the French at Prenzlau. A prisoner in France and Switzerland for the next two years, he returned to Prussia in 1809; and for the next three years, as a departmental chief in the ministry of war, as a teacher in the military school, and as military instructor to the crown prince, he assisted Scharnhorst in the famous reorganization of the Prussian Army. In 1810 he married the countess Marie von Brühl.

On the outbreak of the Russian war in 1812, Clausewitz, like many other Prussian officers, took service with his country's nominal enemy. This step he justified in a memorial, published for the first time in the *Leben Gneisenaus* by Pertz (1869). At first adjutant to Gen. Phull, who had himself been a Prussian officer, he served later under Pahlen at Witepsk and Smolensk, and from the final Russian position at Kaluga he was sent to the army of Wittgenstein. It was Clausewitz who negotiated the convention of Tauroggen, which separated the cause of Yorck's Prussians from that of the French, and began the War of Liberation (*see* YORCK VON WARTENBURG; also Blumenthal's *Die Konvention von Tauroggen*, 1901). As a Russian officer he superintended the formation of the *Landwehr* of east Prussia (*see* STEIN, H. F. K.), and in the campaign of 1813 he served as chief of staff to Count Wallmoden. He conducted the fight at Göhrde, and after the armistice, with Gneisenau's permission, published an account of the campaign (*Der Feldzug von 1813 bis zum Waffenstillstand*, Leipzig, 1813). This work was long attributed to Gneisenau himself. After the peace of 1814 Clausewitz re-entered the Prussian service, and in the Waterloo campaign was present at Ligny and Wavre as Gen. Thielmann's chief of staff. This post he retained till 1818, when he was promoted major-general and appointed director of the *Allgemeine Kriegsschule*. Here he remained till in 1830 he was made chief of the 3rd Artillery Inspection at Breslau. Next year he became chief of staff to Field-marshal Gneisenau, who commanded an army of observation on the Polish frontier. After the dissolution of this army Clausewitz returned to his artillery duties; but on Nov. 18, 1831, he died at Breslau of cholera, which had proved fatal to his chief also, and a little previously, to his old Russian commander Diebitsch on the other side of the frontier.

His collected works were edited and published by his widow, who was aided by some officers, personal friends of the general, in her task. Of the ten volumes of *Hinterlassene Werke über Krieg und Kriegführung* (1832–37, later edition called *Clausewitz's Gesammte Werke*, 1874) the first three contain Clausewitz's masterpiece, *Vom Kriege*, an exposition of the philosophy of war. He produced no "system" of strategy, and his critics styled his work "negative" and asked *"Qu'a-t-il fondé?"* What he had "founded" was that modern strategy which, by its hold on the Prussian mind, carried the Prussian arms to victory in 1866 and 1870, and his philosophy of war became, not only in Germany but in many other countries, the basis of military studies. But it has been argued since the World War that his teaching contributed to the deadlock and costly attrition strategy of 1914–18 through its excessive emphasis on purely military factors, a tendency naturally exaggerated by his disciples. The English and French translations (Graham, *On War*, 1873; Neuens, *La Guerre*, 1849–52; or Vatry, *Théorie de la grande guerre*, 1899), with the German original, place the work at the disposal of students of most nationalities. The remaining volumes deal with military history: vol. 4, the Italian campaign of 1796–97; vols. 5 and 6, the campaign of 1799 in Switzerland and Italy; vol. 7, the wars of 1812, 1813 to the armistice, and 1814; vol. 8, the Waterloo campaign; vols. 9 and 10, papers on the campaigns of Gustavus Adolphus, Turenne, Luxemburg, Münnich, John Sobieski, Frederick the Great, Ferdinand of Brunswick, etc. He also wrote *Über das Leben und den Charakter von Scharnhorst* (printed in Ranke's *Historisch-politischer Zeitschrift*, 1832). A manuscript on the catastrophe of 1806 long remained unpublished. It was used by v. Höpfner in his history of that war, and eventually published by the Great General Staff in 1888 (French translation, 1903). Letters from Clausewitz to his wife were published in *Zeitschrift für preussische Landeskunde* (1876).

See von Meerheimb, *Karl von Clausewitz* (1875), also Memoir in *Allgemeine deutsche Biographie*; Schwartz, *Leben des General von Clausewitz und der Frau Marie von Clausewitz* (2 vols., 1877); Bernhardi, *Leben des Generals von Clausewitz* (10th Supplement, *Militär. Wochenblatt*, 1878).

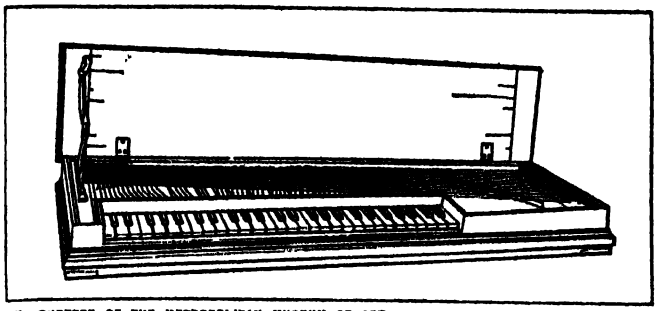
THE CLAVICEMBALO, AN ITALIAN HARPSICHORD OF THE 16TH CENTURY



CLAUSIUS, RUDOLF JULIUS EMMANUEL (1822–1888), German physicist, was born at Köslin, in Pomerania. After attending the Gymnasium at Stettin, he studied at Berlin university from 1840 to 1844. In 1848 he took his degree at Halle, and in 1850 was appointed professor of physics in the royal artillery and engineering school at Berlin and *privatdocent* in the university. In 1855 he became an ordinary professor at Zürich Polytechnic, and professor in the University of Zürich. In 1867 he moved to Würzburg as professor of physics, and two years later was appointed to the same chair at Bonn, where he died. The work of Clausius, who was a mathematical rather than an experimental physicist, was concerned with many of the most abstruse problems of molecular physics. By his restatement of Carnot's principle he put the theory of heat on a truer and sounder basis, and he deserves the credit of having made thermodynamics a science; he enunciated the second law, in a paper contributed to the Berlin Academy in 1850, in the well-known form, "Heat cannot of itself pass from a colder to a hotter body." His results he applied to an exhaustive development of the theory of the steam-engine, laying stress in particular on the conception of entropy. The kinetic theory of gases owes much to his researches. He raised it, on the basis of the dynamical theory of heat, to the level of a theory, and he carried out many numerical determinations in connection with it, *e.g.*, of the mean free path of a molecule. Clausius also made an important advance in the theory of electrolysis, suggesting that molecules in electrolytes are continually interchanging atoms, the electric force not causing, but merely directing the interchange. This view found little favour until 1887, when it was taken up by S. A. Arrhenius, who made it the basis of the theory of electrolytic dissociation. In addition to many scientific papers he wrote *Die Potentialfunktion und das Potential* (1864) and *Abhandlungen über die mechanische Wärmetheorie* (1864–67).

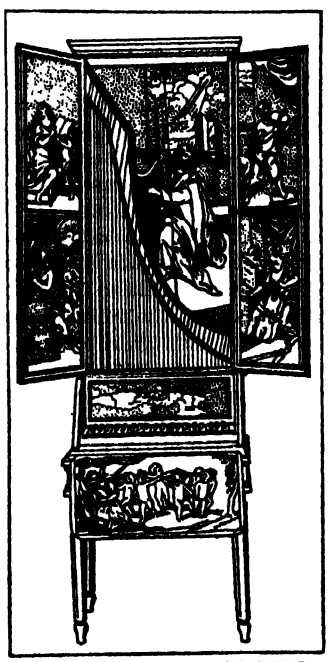
CLAVECIN, the French for "clavicymbal" or "harpsichord" (Ger. *Clavicymbel* or *Dockenklavier*), an abbreviation of the

Flemish *clavisinbal* and Ital. *clavicimbalo*. *See* PIANOFORTE; HARPSICHORD; SPINET; VIRGINAL.

CLAVICEMBALO or **GRAVICEMBALO,** the Italian names for the clavicymbal or harpsichord. "Cymbal" (Gr. *κύμβαλον*, from *κύμβη*, a hollow vessel) was the old European term for the dulcimer, and hence its place in the formation of the word. *See* PIANOFORTE; HARPSICHORD; SPINET; VIRGINAL.

CLAVICHORD or **CLARICHORD,** a mediaeval stringed keyboard instrument, a forerunner of the pianoforte (*q.v.*), its

BY COURTESY OF THE METROPOLITAN MUSEUM OF ART



THE MEDIAEVAL CLAVICHORD, A FORERUNNER OF THE PIANO
This instrument differed from the harpsichord in that its strings were struck by tangents, instead of being plucked or twanged by quills. Its tone, though weak, was very delicate and sweet

strings being set in vibration by a blow from a brass tangent instead of a hammer as in the modern instrument.

The clavichord, derived from the dulcimer by the addition of a keyboard, has a long history, being mentioned as early as 1404 in Eberhard Cersne's *Rules of the Minnesingers.*

There were two kinds of clavichords—the fretted or *gebunden* and the fret-free or *bund-frei*. The term "fretted" was applied to those clavichords which, instead of being provided with a string or set of strings in unison for each note, had one set of strings acting for three or four notes, the arms of the keys being twisted in order to bring the contact of the tangent into the acoustically correct position under the string. The "fret-free" were chromatically-scaled instruments.

The first *bund-frei* clavichord is attributed to Daniel Faber of Crailsheim in Saxony about 1720. This important change in construction increased the size of the instrument, each pair of unison strings requiring a key and tangent of its own, and led to the introduction of the system of tuning by equal temperament upheld by J. S. Bach and practically illustrated by him in his immortal "Wohltemperirtes Clavier" ("Well-tempered Clavier") written expressly to encourage its adoption.

A 17TH CENTURY ITALIAN CLAVICYTHERIUM, OR CLAVIHARP, A VERTICAL SPINET

The tone of the clavichord, extremely sweet and delicate, was characterized by a tremulous hesitancy, which formed its great charm, though its very limited power rendered it unsuitable for use in large rooms or concert halls. Nevertheless, on account of the scope which it afforded for individual expression, it was a favourite instrument with all the best musicians in its day. Bach is said to have preferred it to the harpsichord, Mozart loved to play on it, while even Beethoven, though himself long accustomed to the pianoforte, spoke of it as the most expressive of all keyboard instruments.

CLAVICYTHERIUM, a name usually applied to an upright spinet (*q.v.*), the soundboard and strings of which were vertical instead of horizontal, being thus perpendicular to the keyboard; but it would seem that the clavicytherium proper is distinct from the upright spinet in that its strings are placed *horizontally*. In a unique specimen with two keyboards dating from the 16th or 17th century, which is in the collection of Baron Alexandre Kraus, what appear to be vibrating strings stretched over a soundboard perpendicular to the keyboard are in reality the wires forming part of the mechanism of the action. The instrument was probably of Italian or possibly South German origin and it may be noted that its name has also been applied at times to the upright harpsichord.

There is a very fine specimen of the so-called clavicytherium (really an upright spinet) in the Donaldson museum of the Royal College of Music, London, acquired from the Correr collection at Venice in 1885.

For the history of the clavicytherium considered as a forerunner of the pianoforte, *see* PIANOFORTE.

CLAVIE, BURNING THE, an ancient Scottish custom still observed at Burghead, a fishing village on the Moray firth, near Forres. The "clavie" is a bonfire of casks split in two, lighted on Jan. 12, corresponding to the New Year of the old calendar. One of these casks is joined together again by a huge nail (Lat. *clavus;* hence the term). It is then filled with tar, lighted and carried flaming round the village, and finally up to a headland upon which stands the ruins of a Roman altar, locally called "the Douro." It here forms the nucleus of the bonfire, which is built up of split casks. When the burning tar-barrel falls in pieces the people scramble to get a lighted piece with which to kindle the New Year's fire on their cottage hearth. The charcoal of the clavie is collected and is put in pieces up the cottage chimneys to keep spirits and witches from coming down.

CLAVIÈRE, ÉTIENNE (1735–1793), French financier and politician, was born in Geneva on Jan. 27, 1735. He was a political refugee in England, and in 1789 went to France, where he assisted Mirabeau on the *Courrier de Provence* and in the preparation of his speeches. Clavière also published some pamphlets under his own name, and through these and his friendship with J. P. Brissot, whom he had met in London, he became minister of finance in the Girondist ministry, from March to June 12, 1792. After Aug. 10 he was again given charge of the finances in the provisional executive council. He shared in the fall of the Girondists, and was arrested on June 2, 1793. On receiving notice (Dec. 8) that he was to appear on the next day before the revolutionary tribunal, he committed suicide.

CLAVIJO, RUY GONZALEZ DE (d. 1412), Spanish traveller, was born in Madrid. On the return of the Embassy from the court of Timur, Henry III. of Castille sent out another, which included Clavijo. They sailed from St. Mary Port, near Cadiz, on May 22, 1403, touched at the Balearic isles, Gaeta, Rhodes and Constantinople, went by the south coast of the Black sea to Trebizond, and proceeded inland by Erzerum, Tabriz, Teheran and Meshed to Samarkand, where they were favourably received. They returned successfully after great difficulties and reached Spain on March 1, 1406. Clavijo lived in Madrid and died on April 2, 1412. His narrative is the first important one of its kind in Spanish literature.

BIBLIOGRAPHY.—An English version of Clavijo's narrative, by Sir Clements Markham, was issued by the Hakluyt Society in 1859 (*Narrative of the Embassy of R . . . G . . . Clavijo to the Court of Timour*). For the identification of the places mentioned by Clavijo *see* Khanikof's list in *Geographical Magazine* (1874), and Sreznevski's *Annotated Index* in the Russian edition of 1881. A short account of Clavijo's life is given by Alvarez y Baena in the *Hijos de Madrid*, vol. ix. *See* also C. R. Beazley, *Dawn of Modern Geography*, iii.

CLAVIJO Y FAJARDO, JOSÉ (1726–1806), Spanish publicist, was born at Lanzarote (Canary islands). He settled in Madrid, became editor of *El Pensador*, and by his campaign against the public performance of *autos sacramentales* secured their prohibition in 1765. His work would long since have been forgotten were it not that it put an end to a peculiarly national form of dramatic exposition, and that his love affair with one of Beaumarchais' sisters suggested the theme of Goethe's first publication, *Clavigo*.

CLAVILUX, a keyed projection instrument which makes possible the use of light as a medium for aesthetic expression. It was invented by the American artist, Thomas Wilfred, who gave the new art of light its first comprehensible status with the theory that form, colour and motion are its three basic factors. The instrument consists of a number of projectors grouped before a large white screen and controlled from a keyboard that is either attached to the projectors or placed at a distance. The keys, which slide in grooves graduated from 0 to 100, are grouped in tiers, each comparable to a pipe-organ manual. A tier contains three sets of keys connected with the form, colour and motion-producing devices in the corresponding projector in which a strong beam of white light from an incandescent lamp, after passing through the three devices, is projected on the screen as one or more mobile images depending in form, colour and motion upon the positions and movements of the various keys. A skilled player may select to play a silent visual composition previously written by another artist and recorded by means of a special notation system. The instrument has also been used for visual accompaniments to music, dance and drama, in the latter instance permitting projected scenery and a much more delicate control of lighting than is possible by means of the electrician's switchboard. (T. WI.)

CLAY, CASSIUS MARCELLUS (1810–1903), American politician, was born in Madison county, Ky., on Oct. 19, 1810. He was the son of Green Clay (1757–1826), a Kentucky soldier of the War of 1812 and a relative of Henry Clay. He was educated at Centre college, Danville, Ky., and at Yale, where he graduated in 1832. Influenced to some extent by William Lloyd Garrison, he became an advocate of the abolition of slavery. In 1835, 1837 and 1840 he was elected as a Whig to the Kentucky legislature, where he advocated a system of gradual emancipation. In 1845 he established, at Lexington, Ky., an anti-slavery publication known as *The True American,* but in the same year his office and press were wrecked by a mob, and he removed the publication office to Cincinnati, Ohio. In 1856 he joined the Republican Party, and wielded considerable influence as a Southern representative in its councils. In 1861 he was sent by President Lincoln as minister to Russia; in 1862 he returned to America to accept a commission as major-general of volunteers, but in 1863 was reappointed to his former post at St. Petersburg, where he remained until 1869. Disapproving of the Republican policy of reconstruction, he left the party, and in 1872 was largely instrumental in securing the nomination of Horace Greeley for the presidency. In the political campaign of 1884 he rejoined the Republican Party. He died at Whitehall, Ky., on July 22, 1903.

See his autobiography, *The Life, Memoirs, Writings and Speeches of Cassius Marcellus Clay* (Cincinnati, 1896); and *The Writings of Cassius Marcellus Clay* (edited with a "Memoir" by Horace Greeley, 1848).

CLAY, CHARLES (1801–1893), English surgeon, was born at Bredbury, near Stockport, on Dec. 27, 1801. He qualified at Edinburgh in 1823 and settled in Manchester as a consultant in 1839. In 1842 he first performed the operation of ovariotomy with which his name is associated, and in 1865 was able to show an analysis of 111 cases with a mortality slightly over 30%. Clay was a man of many interests and included geology, numismatics and book collecting among his pursuits. He died at Poulton-le-Fylde, near Preston, on Sept. 19, 1893.

CLAY, FREDERIC (1838–1889), English musical composer, was the son of James Clay, M.P., the celebrated whist authority. Born in Paris, he studied music under W. B. Molique in that city and under Moritz Hauptmann at Leipzig. With the exception of a few songs and two cantatas, *The Knights of the Cross* (1866) and *Lalla Rookh* (1877),—the latter of which contained his well-known song "I'll sing thee songs of Araby,"—his compositions were written for the stage, and have long since been forgotten. Two of them, *Ages Ago* (1869) and *Princess Toto* (1875) were written to libretti by W. S. Gilbert. Clay's last works, *The Merry Duchess* (1883) and *The Golden Ring* (1883), showed an advance upon his previous work, and rendered all the more regrettable the stroke of paralysis which crippled him physically and mentally during the last few years of his life.

CLAY, HENRY (1777–1852), American statesman and orator, was born in Hanover county, Va., on April 12, 1777, and died in Washington on June 29, 1852. His public life covered nearly half a century, and his name and fame rest entirely upon his own merits. He achieved his success despite serious obstacles. He was tall, rawboned and awkward; his early instruction was scant; but he read books, talked well, studied law under George Wythe, the teacher of Jefferson and Marshall, and so, after his admission to the bar at Richmond, Va., in 1797 and his removal next year to Lexington, Ky., he quickly acquired a reputation and a lucrative income from his law practice.

Thereafter, until the end of life, and in a field where he met, as either friend or foe, John Quincy Adams, Gallatin, Madison, Monroe, Webster, Jackson, Calhoun, Randolph and Benton, his political activity was wellnigh ceaseless. At the age of 22 (1799) he was elected to a constitutional convention in Kentucky; at 26, to the Kentucky legislature; at 29, while yet under the age limit of the U.S. Constitution, he was appointed to an unexpired term (1806–7) in the U.S. Senate, where, contrary to custom, he at once plunged into business as though he had been there all his life. He again served in the Kentucky legislature (1808–9), was chosen speaker of its lower house, and achieved distinction by preventing an intense and widespread anti-British feeling from excluding the common law from the Kentucky code. A year later he was elected to another unexpired term in the U.S. Senate, serving in 1810–11. At 34 (1811) he was elected to the U.S. House of Representatives and chosen speaker on the day of his entrance. During the 14 years following his first election, he was re-elected five times to the House and to the speakership; retiring for one term (1821–23) to resume his law practice and retrieve his fortunes. He thus served as speaker in 1811–14, in 1815–20 and in 1823–25. Once he was unanimously elected by his constituents, and once nearly defeated for having at the previous session voted to increase congressional salaries. From 1825 to 1829 he served as secretary of State in President John Quincy Adams's cabinet, and in 1831 he was elected to the U.S. Senate, where he served until 1842, and again from 1849 until his death. Between 1824 and 1848 he was a strong presidential candidate in nearly every campaign.

One of the chief sources of Clay's immediate popularity when first elected to the House in 1811, was his championship of the War of 1812 with Great Britain, which his influence, more than that of any other man, precipitated. While not, perhaps, an altogether advantageous or necessary war, it won the youthful nation the respect of European nations, and a greater independence of them than she had hitherto known. Clay was sent to Ghent as one of the peace commissioners, and signed the treaty, though reluctantly, for he was disappointed in the silence concerning the questions of impressment of American sailors, the fisheries, and the navigation of the Mississippi.

After the war Clay and Calhoun became the foremost champions of the Democratic Republican Party in Congress. Clay refused appointments as minister to Russia and to England, as well as the secretaryship of war under both Madison and Monroe that he might devote his attention to his congressional programme, the three most important features of which were the inauguration of internal improvements, the establishment of a national bank, and the levying of a tariff high enough to build up industries needed in time of war. As a protectionist Clay in 1824 again advocated high duties to relieve the prevailing distress, which he pictured in a brilliant and effective speech. In spite of the opposition of Webster, Calhoun and other prominent statesmen, Clay succeeded in enacting a tariff so high that the people of the Southern States denounced it as a "tariff of abominations." When it overswelled the revenue in 1832 he favoured reducing the rates on all articles not competing with American products, but the new measure reduced the revenue so little and provoked such serious threats of nullification and secession in South Carolina, that to prevent bloodshed and to forestall a free trade measure from the next Congress, Clay brought forward in 1833 a compromise measure for the gradual reduction of the tariff to a 20% ad valorem basis extending over a period of nine years. It lost Clay

the support of ardent protectionists but was hailed with favour by the people at large.

Clay's interest in internal improvements resulted naturally from his interest in western expansion and development. He supported the Federal financing or aiding of roads, canals and other schemes of transportation which would bind the east and west together. For a time he argued for the return to individual States of the receipts from all public lands sold within its borders.

BY COURTESY OF THE LEXINGTON CHAMBER OF COMMERCE

"ASHLAND," THE HOME OF HENRY CLAY IN LEXINGTON, KY.

This plan, together with many of his special projects, failed, but the general impetus of his oratory and argument was not lost.

Clay also interested himself passionately in the struggle of the South American nations for their independence. He made resounding speeches in the House in favour of the "eighteen millions of people struggling to burst their chains." He advocated an alliance in the two Americas to counterbalance the Holy Alliance of Europe and work against its designs. He was among the first to recommend recognition of the new nations by the United States, and consequently is still remembered with affection by them. Similarly, in 1824, he made an impassioned speech in favour of Greek independence and supported Webster's resolution for sending an agent or commissioner to that country.

But of all causes and questions, Clay's career was connected most intimately with that of slavery. When only 22 Clay had vainly urged an emancipation clause for the new constitution of Kentucky and never ceased to regret its failure. In 1820 he congratulated the new South American republics on having abolished slavery, pointing out that in this important point of progress they were in advance of the United States. The same year, however, threats of the Southern States to destroy the Union led him to advocate the "Missouri Compromise," which, while keeping slavery out of all of the rest of the territory included in the "Louisiana Purchase" north of Missouri's southern boundary, permitted it in that State. When the slave power became more aggressive in and after the year 1831, Clay defended the right of petition for the abolition of slavery in the District of Columbia, and opposed Calhoun's bill forbidding the use of the mails to "abolition" newspapers and documents. Though he favoured the freedom of the mails and press as regards slavery, he disliked the abolitionists and, because of their insistent, uncompromising demands, held them largely responsible for the hatred and strife which menaced the Union. Clay was lukewarm toward recognizing the independence of Texas lest it should aid the increase of slave territory. Yet he was so anxious to set himself right with the South that he prepared an elaborate speech for the purpose which received pro-slavery approval. His attitude resulted, as he himself declared, in the abolitionists denouncing him as slave-holder, and the slave-holder as an abolitionist. Such straddling undoubtedly was a prime factor in his loss of the presidency, which he always held in view. In 1844, for instance, while a candidate for the presidency, he announced himself against the annexation of Texas, but on other grounds than slavery. By not pronouncing definitely on the real issue he lost supporters from men of both pro-slavery and anti-slavery sentiments instead of winning them as he had hoped. His compromising spirit upon the question promised to bear fruit, however, when in the crisis of 1850 he was able to bring about the series of measures known collectively as the "Compromise of 1850." The situation was acute, the South was on the point of secession, statesmen were frantic, every way of alleviating the deadlock seemed to have failed. Clay, who had retired from the Senate several years before, was now an old and physically frail man, but had himself re-elected to that body where he could put forth and defend his measures. His speech was one of the ablest of his career. Webster in a notable speech seconded the measures as a last resort. Calhoun still bitterly opposed. A deadlock resulted because of the opposition of President Taylor to the plan, and was only removed upon the latter's death, whereupon Fillmore, friendly to the compromise, succeeded to his place. The compromise admitted California as a free State, organized Utah and New Mexico as territories without reference to slavery, and enacted a more efficient fugitive slave law. It was a noble climax to Clay's great career, but it did not, as he hoped, permanently save the Union from bloodshed. Its success was in the fact that it postponed the Civil War until the North had the immense growing power of the West as its ally. Clay did not live to see its failure, but died in 1852 at the height of his fame and popularity.

In one respect, however, Clay's whole political career had been a bitter disappointment, at least to the man himself. The nation never rewarded him with the highest office in its power to bestow, and which he so deeply coveted. This was in spite of the fact that for a generation he was the acknowledged leader of his party. One reason was that during the whole period sectional feeling was so strong that no leader of any one section could be elected. Peace had to be secured by choosing lesser men as compromise candidates. Another reason was Clay's own compromising nature which always won him enemies in both camps. His name was used comparatively early in connection with the presidency. He had hoped to be offered the office of secretary of State under Monroe in 1817, for at that time this official was regarded as next in line for the succession. Clay was greatly disappointed and pursued a policy of obstruction to the administration until the events culminating in the Missouri Compromise again led him to co-operate with Monroe. In 1824 Clay was a candidate with W. H. Crawford, Andrew Jackson and John Quincy Adams for the presidency. Choice between the two highest, Jackson and Adams, went to the House where Clay controlled the deciding vote. Though Jackson represented the West and its interests, to choose him would have meant the denial of all chances for himself in the following campaign, for the country would not be likely to choose two western leaders in succession. Temperamentally Clay was also opposed to Adams, but after a long conference he gave out that he would support the latter. Soon afterwards he accepted an appointment as secretary of State, under Adams, and Jackson's supporters immediately charged a corrupt bargain between the two. Historians generally feel that Clay sincerely favoured Adams, but ever after Clay was kept busy explaining and denying the allegation of a bargain. It made Jackson his bitter enemy for life. John Randolph of Virginia pressed the accusation until Clay hotly consented to a duel to defend his honour. Neither was hurt. Clay's action so alienated his western supporters that it also must be ascribed as one of the reasons why he never achieved the presidency. In fact when he finished his term as secretary of State he had to go home "to mend his fences" in order to ensure his re-election to Congress. It proved the most difficult and most important campaign of his life, for, had he failed, it would have meant the eclipse of his political career.

By his enemies Clay's compromises were often ascribed to timidity or to hedging for political purposes. They can just as truly be represented as the acts of a man of great human understanding and sympathies, anxious to enter into the point of view of others. There is every indication that they represent a philosophical attitude toward life. "All legislation, all government, all society is founded upon the principle of mutual concession, politeness, comity, courtesy . . . I bow to you today because you bow to me." Such were his words and sentiments. The compromises represent his greatest political achievements. As "the great pacificator" he occupies a place in the memory of his countrymen.

When not in Washington Clay's home was on his estate at Ashland, Kentucky. He took a great interest in its practical man-

agement and especially devoted himself to the breeding of beautiful Kentucky horses. He was an excellent rider. Though Clay repeatedly denounced slavery as an evil, tradition and habit allowed him to keep slaves on his own plantation. He treated them considerately and they were devoted to him. When very young Clay married Lucretia Hart, a cousin of Thomas Hart Benton. Five sons and six daughters were born to them. But misfortune seemed to hang over the family. All of the daughters died before the father. One son was killed in the Mexican War, and another became insane after an accident. Clay's acquaintances and friends were selected from all classes and occupations. His popularity with the people was immense, and he believed in them. Yet like many democratic leaders, notably his great western rival, Andrew Jackson, Clay was often arbitrary, autocratic and possessed of an irrepressible desire to rule. His imagination frequently ran away with his understanding while his imperious temper and ardent combativeness hurried him into disadvantageous positions. Great crowds always met him wherever he was to speak because of his matchless voice and fascinating personality. In public he was of magnificent bearing, possessing the true oratorical temperament, the nervous exaltation that makes the orator feel and appear a superior being, transfusing his thought, passion and will into the mind and heart of the listener. In private he was an excellent conversationalist, possessing a fund of pleasant humour. His never-failing courtesy, his agreeable manners and a noble and generous heart for all who needed protection against the powerful or the lawless endeared him to hosts of friends.

Clay, *Henry Clay* (1910); Gamaliel Bradford, "Henry Clay," in *Virginia Quarterly Review*, Jan. 1928. Much material will be found in the standard histories of the period and in Thomas H. Benton's *Thirty Years View* (1861). No complete and critical biography yet exists.

CLAY AND CLAY MINERALS. The term clay has been used in several senses: (1) to designate particle size, about minus 0.004 mm.; (2) as a rock composed essentially of clay materials; and (3) as a name for a group of minerals—the clay minerals. As a rock name it comprises soils, ceramic clays, clay shales, mudstones, glacial clays—including great volumes of detrital and transported clays—and the oceanic clays, red clay, blue clay and blue mud. These are all characterized by one or more of the clay minerals together with varying amounts of detrital and organic materials, among which quartz is dominant. Clay materials are plastic when wet, water retentive, and coherent when dry. Most clays are the result of weathering, but some are formed by hydrothermal processes. They are one of the major mineral products, being used in a wide variety of industries; and they provide the mechanical and chemical environment for almost all plant growth, and hence for nearly all the life on the earth's surface.

Clay minerals are divided into three main groups, all being characterized by a sheetlike crystal structure:

Kaolinite group	kaolinite, dickite, nacrite halloysite;
Montmorillonite group	montmorillonite aluminian montmorillonite (beidellite) nontronite, saponite, hectorite sauconite;
Potash clay variously called	hydromica, hydrous mica, illite, glimmerton (German) bravaisite.

Kaolinite, dickite, halloysite and nacrite have the same chemical composition ($Al_2O_3.2SiO_2.2H_2O$) and differ only in their crystal structure. The related mineral endellite contains twice as much water and loses half of it at 60° C., changing to halloysite. Allophane, a material without crystal structure (amorphous) and with variable chemical composition, occurs widely as a product of weathering that is not assignable to any mineral group.

The montmorillonite group can be presented by means of ion substitutions in the chemical formula of the related mineral, pyrophyllite [$Al_2Si_4O_{10}(OH)_2$]. In typical montmorillonite about one-sixth of the aluminum is proxied by magnesium, and such exchangeable ions as calcium, sodium, potassium, hydrogen and some magnesium are held between the sheets of the crystal lattice (the so-called exchangeable bases). Variable amounts of loosely held water occupy a position between the crystal sheets. Various ions may proxy aluminum in the crystal structure. If this is iron, the mineral is nontronite; if magnesium, it is saponite or hectorite; and if zinc, it is sauconite. A limited proportion of aluminum may proxy silicon. In the crystal structure approximately three bivalent ions (magnesium, zinc) may proxy trivalent ions (aluminum, iron), which occupy only two of three potential octahedral positions in the crystal structure.

The hydrous mica group has not been adequately studied. It seems to range in chemical composition from potash-bearing montmorillonite on the one hand to micas on the other. A material with about half the potassium oxide of mica (about 6%) occurs widely. Preliminary studies suggest that the group includes potash-bearing montmorillonite, mixed layers of more than one of the various sheet materials and materials closely related to muscovite mica.

Ion exchange in clays plays a major role in plant growth, being a reservoir of potassium oxide, calcium oxide and even nitrogen. It also is a factor in industry in water softeners and oil clarification, with or without acid treatment. Montmorillonites have a high ion exchange capacity (60 to 100 miliequivalents per 100 g.); potash clays have roughly half as much, but in the kaolinite group it is slight.

The purest available source of montmorillonite is bentonite, a clay resulting from the alteration of volcanic ash. With calcium as the exchangeable ion it is treated with acid and used in petroleum refining. With sodium it is highly dispersable (colloidal) and has wide use as an absorbant.

Uses.—No other earth material has so wide an importance or such extended uses as do clays. Their properties as soils are dependent on their providing the physical environment for plant growth; that is, porosity, aeration and water retention. Clays are the storehouse of chemical fertility, base exchange being a fundamental property. The use of clay in pottery making antedates recorded human history, and pottery remains are a major record of past civilizations. In western Asia the hieroglyphics inscribed on tiles played a major role in ancient culture. As building materials, bricks (baked and as adobe) have been used in construction since earliest time. Brick, tile and the cruder types of pottery have used impure clays but even the early potters learned to add ground rock or previously baked clay (grout) and even volcanic ash. The finer grades of ceramic materials have made use of white clay or kaolin, in which kaolinite is the characteristic clay mineral. To this are usually added ground quartz (flint), ground feldspar and ball clay to increase plasticity. Refractory materials, including fire brick, chemical ware and melting pots for glass, make use of kaolin together with other materials which increase resistance to heat. Certain clays known as fuller's earths have long been used in wool scouring. A large use of clays (bentonite, halloysite and altapulgite) is in the refining of both organic and mineral oils, commonly after activation by means of acid treatment.

A major use of white clays is as paper fillers; they give the paper a gloss and increase opacity and printability.

In rubber compounding, the addition of clay increases resistance to wear and aids in the elimination of moulding troubles.

The essential raw materials of portland cement are limestone and clays (commonly impure ones). These are ground together, sintered and then ground to a fine powder. On the addition of water, the calcium, aluminum and silicon combine into crystals of hydrous-alumina silicates, and the material sets.

Clay materials have a wide variety of uses in engineering. Earth dams are made impermeable to water by adding suitable clay materials to porous soil materials; commonly this is an impermeable core. Water loss in canals may be reduced by adding clay materials.

Clays after acid treatment have been used as water softeners. The base exchange property permits the clay to remove calcium from solution and substitutes sodium. A major use of bentonitic clay is as drilling muds. These prevent flocculation and their circulation removes the drill cuttings of the rotary drill. A heavy material (barite is commonly used) may be added to the mud, and the high hydrostatic head thus developed prevents explosive escape of natural gas.

Other minor uses of clays in various forms, too numerous to describe in detail, are in cosmetics, crayons, pencils, insecticides (as carriers), insulating materials, medicine, oil cloths, paints, soap and detergents, tooth powders and phonograph records. (CL. S. R.)

CLAY CROSS, an urban district of Derbyshire, England, near the river Amber, on the railway, 1½ mi. S. of Chesterfield. Pop. (1951) 8,552. Area 3.2 sq.mi. Coal miners and foundry workers form the majority of the population.

CLAYMORE (from the Gaelic *claidheamh mòr*, "great sword"), the old two-edged broadsword with cross hilt, of which the guards were usually turned down, used by the Highlanders of

Scotland. The name is also wrongly applied to the single-edged basket-hilted sword adopted in the 16th century and still worn as the full-dress sword in the Highland regiments of the British army.

CLAYS, PAUL JEAN (1819–1900), Belgian marine painter, was born at Bruges in 1819, and died at Brussels in 1900. A Fleming in his feeling for colour, Clays set his palette with clean, strong hues, and their powerful harmonies were in striking contrast with the rusty, smoky tones then in favour. If he was not a "luminist" in the modern use of the word, he deserves at any rate to be classed with the founders of the modern naturalistic school. Among his works are: "Dutch Boats in the Flushing Roads," in the National Gallery, London; "The Port of Antwerp," "Coast near Ostend," and a "Calm on the Scheldt," in the Brussels gallery; "The Meuse at Dordrecht" in the Antwerp museum; "The Open North Sea," in the Pinakothek at Munich; and "The Festival of the Freedom of the Scheldt at Antwerp in 1863," in the Metropolitan Museum of Fine Arts, New York.

See Camille Lemonnier, *Histoire des Beaux-Arts* (Brussels, 1887).

CLAYTON, JOHN MIDDLETON (1796–1856), American politician, was born in Dagsborough, Del., on July 24, 1796. He came of an old Quaker family long prominent in the political history of Delaware. He graduated at Yale in 1815, and in 1819 began to practise law at Dover, Delaware. Engaging in politics, he became in 1824 a member of the state house of representatives, and in 1826–28 was secretary of state for Delaware. In 1829 he was elected to the U.S. Senate by the anti-Jackson forces, and in 1835 was re-elected as a Whig, but resigned in 1836. In 1845 he again entered the Senate, where he opposed the annexation of Texas and the Mexican War. In March, 1849, he became secretary of state in President Taylor's cabinet. His brief tenure of the state portfolio, which terminated July 22, 1850, soon after Taylor's death, was notable chiefly for the negotiation with the British minister, Sir Henry Lytton Bulwer of the Clayton-Bulwer Treaty (*q.v.*). He was once more a member of the Senate from March, 1853, until his death at Dover, Del., Nov. 9, 1856. By his contemporaries Clayton was considered one of the ablest debaters and orators in the Senate.

See the memoir by Joseph P. Comegys in the *Papers* of the Historical Society of Delaware, No. 4 (Wilmington, 1882).

CLAYTON-BULWER TREATY, a famous treaty between the United States and Great Britain, negotiated in 1850 by John M. Clayton and Sir Henry Lytton Bulwer (Lord Dalling) in consequence of the situation created by the project of an interoceanic canal across Nicaragua, each signatory being jealous of the activities of the other in Central America. Great Britain had large and indefinite territorial claims in three regions—Belize or British Honduras, the Mosquito Coast and the Bay islands. On the other hand, the United States, without territorial claims, held in reserve, ready for ratification, treaties with Nicaragua and Honduras, which gave her a certain diplomatic vantage with which to balance the *de facto* dominion of Great Britain.

The treaty bound both parties not to "obtain or maintain" any exclusive control of the proposed canal, or unequal advantage in its use. It guaranteed the neutralization of such canal. It declared that, the intention of the signatories being not only the accomplishment of "a particular object"—*i.e.*, that the canal, then supposedly near realization, should be neutral and equally free to the two contracting powers—"but also to establish a general principle," they agreed "to extend their protection by treaty stipulation to any other practicable communications, whether by canal or railway, across the isthmus which connects North and South America." Finally, it stipulated that neither signatory would ever "occupy, or fortify, or colonize, or assume or exercise any dominion over Nicaragua, Costa Rica, the Mosquito Coast or any part of Central America," nor make use of any protectorate or alliance, present or future, to such ends.

The treaty was signed on April 19, and was ratified by both Governments; but before the exchange of ratifications Lord Palmerston, on June 8, directed Sir H. Bulwer to make a "declaration" that the British Government did not understand the treaty "as applying to Her Majesty's settlement at Honduras, or its dependencies." J. M. Clayton made a counter-declaration, which recited that the United States did not regard the treaty as applying to "the British settlement in Honduras commonly called British-Honduras . . . nor the small islands in the neighbourhood of that settlement which may be known as its dependencies"; that the treaty's engagements did apply to all the Central American States, "with their just limits and proper dependencies"; and that these declarations, not being submitted to the United States Senate, could of course not affect the legal import of the treaty. The interpretation of the declarations soon became a matter of contention. The phraseology reflects the effort made by the United States to render impossible a physical control of the canal by Great Britain through the territory held by her at its mouth—the United States losing the above-mentioned treaty advantages—just as the explicit abnegations of the treaty rendered impossible such control politically by either power. But Great Britain claimed that the excepted "settlement" at Honduras was the "Belize" covered by the extreme British claim; that the Bay islands were a dependency of Belize; and that, as for the Mosquito Coast, the abnegatory clauses being wholly prospective in intent, she was not required to abandon her protectorate. The United States contended that the Bay islands were not the "dependencies" of Belize, these being the small neighbouring islands mentioned in the same treaties; that the excepted "settlement" was the British-Honduras of definite extent and narrow purpose recognized in British treaties with Spain; that she had not confirmed by recognition the large, indefinite and offensive claims whose dangers the treaty was primarily designed to lessen; and that, as to the Mosquito Coast, the treaty was retrospective, and that the clause binding both not to "occupy" any part of Central America or the Mosquito Coast necessitated the abandonment of such territory as Great Britain was already actually occupying or exercising dominion over, and the complete abandonment of the British protectorate over the Mosquito Indians. It seems to be a just conclusion that when in 1852 the Bay islands were erected into a British "colony" this was a flagrant infraction of the treaty; that as regards Belize the American arguments were decidedly stronger, and more correct historically; and that as regards the Mosquito question, inasmuch as a protectorate seems certainly to have been recognized by the treaty, to demand its absolute abandonment was unwarranted, although to satisfy the treaty Great Britain was bound materially to weaken it.

In 1859–60, by British treaties with Central American States, the Bay islands and Mosquito questions were settled nearly in accord with the American contentions. But by the same treaties Belize was accorded limits much greater than those contended for by the United States. This settlement the latter power accepted without cavil for many years.

In 1880–84 a variety of reasons were advanced why the United States might justly repudiate at will the Clayton-Bulwer Treaty. The arguments advanced were quite indefensible in law and history, and although the position of the United States in 1850–60 was in general the stronger, that of Great Britain was even more conspicuously strong in the years 1880–84. In 1885 the former Government reverted to its traditional policy, and the Hay-Pauncefote Treaty of 1902, which replaced the Clayton-Bulwer Treaty, adopted the rule of neutralization for the Panama Canal.

See the collected diplomatic correspondence in I. D. Travis, *History of the Clayton-Bulwer Treaty* (Ann Arbor, Mich., 1899); J. H. Latané, *Diplomatic Relations of the United States and Spanish America* (Baltimore, 1900); T. J. Lawrence, *Disputed Questions of Modern International Law* (2nd ed., Cambridge, England, 1885); Sir E. L. Bulwer in 99 *Quarterly Rev.* 235–286, and Sir H. Bulwer in 104 *Edinburgh Rev.* 280–298.

CLAY-WITH-FLINTS, in geology, a name given to a deposit of stiff red, brown or yellow clay, containing many flints, whole or broken, with some round pebbles of hard rock. It covers large areas in south-eastern and southern England, usually lying on chalk. It is commonly considered to represent the insoluble residue of the chalk left by weathering (mainly solution), but may include deposits formed in other ways, of which the following have been suggested: (*a*) that it is the residue of patches of Tertiary strata which once extended more widely over the chalk

than at present. This is favoured by the presence of pebbles other than flint: (*b*) that it may be a glacial deposit, in fact, a boulder-clay or till, indicating an extension of the ice-sheet somewhat further than is usually believed. (*See* GLACIAL EPOCH.) These questions must be regarded as still undecided, but there can be little doubt that the insoluble residue theory is applicable over wide areas. (R. H. RA.)

CLAZOMENAE, an ancient town of Ionia and a member of the Ionian Dodecapolis (Confederation of Twelve Cities), on the Gulf of Smyrna, about 20 m. W. of that city. Though not in existence before the arrival of the Ionians in Asia, its original founders were largely settlers from Phlius and Cleonae. It stood originally on the isthmus connecting the mainland with the peninsula on which Erythrae stood; but the inhabitants, alarmed by the encroachments of the Persians, removed to one of the small islands of the bay, and there established their city. This island was connected with the mainland by Alexander the Great by means of a pier, the remains of which are still visible. During the 5th century it was for some time subject to the Athenians, but about the middle of the Peloponnesian war (412 B.C.) it revolted. After a brief resistance, however, it again acknowledged the Athenian supremacy, and repelled a Lacedaemonian attack. Under the Romans Clazomenae was included in the province of Asia, and enjoyed immunity from taxation. It was the birthplace of the philosopher Anaxagoras. It is famous for its painted terracotta sarcophagi, which are the finest monuments of Ionian painting in the 6th century B.C. (E. GR.)

CLEANING: *see* DRY CLEANING.

CLEANTHES (*c.* 301–232 or 252 B.C.), Stoic philosopher, was born at Assos in the Troad. He came to Athens, where he listened first to the lectures of Crates the Cynic, and then to those of Zeno the Stoic, supporting himself meanwhile by working all night as water-carrier to a gardener (hence his nickname *φρεάντλης*). On the death of Zeno in 263, he became the leader of the school. Among his pupils were his successor, Chrysippus, and Antigonus, king of Macedon.

Cleanthes produced very little that was original, though he wrote some 50 works, of which fragments have come down to us. The principal is the large portion of the *Hymn to Zeus,* which has been preserved in Stobaeus. He regarded the sun as the abode of God, the intelligent providence, or (in accordance with Stoic materialism) the vivifying fire or aether of the universe. Virtue, he taught, is life according to nature; but pleasure is not according to nature. The principal fragments of Cleanthes' works are contained in Diogenes Laertius and Stobaeus; some may be found in Cicero and Seneca.

See G. C. Mohinke, *Kleanthes der Stoiker* (Greifswald, 1814); C. Wachsmuth, *Commentationes de Zenone Citiensi et Cleanthe Assio* (Göttingen, 1874–75); A. C. Pearson, *Fragments of Zeno and Cleanthes* (1891); art. by E. Wellmann in Ersch and Gruber's *Allgemeine Encyklopädie;* R. Hirzel, *Untersuchungen zu Ciceros philosophischen Schriften,* ii. (1882), containing a vindication of the originality of Cleanthes; *Hymn of Cleanthes,* tr. E. H. Blakeney, "Texts for Students" series, vol. xxvi. (1921); A. B. Krische, *Forschungen auf dem Gebiete der alten Philosophie* (1840); also works quoted under STOICS.

CLEARCHUS, the son of Rhamphias, a Spartan general and condottiere. Born about the middle of the 5th century B.C., Clearchus was sent with a fleet to the Hellespont in 411 and became harmost of Byzantium. His severity, however, made him unpopular, and in his absence the gates were opened to the Athenians under Alcibiades (409). Subsequently appointed by the ephors to settle the affairs of Byzantium and to protect it from Thracian attacks, he made himself tyrant, and, when driven thence by a Spartan force, fled to Cyrus (*q.v.*). In the "expedition of the ten thousand," Clearchus led the Peloponnesians. On Cyrus's death Clearchus conducted the retreat, until, being treacherously seized with his fellow-generals by Tissaphernes, he was handed over to Artaxerxes and executed (Thuc. viii. 8, 39, 80; Xen., *Hellenica,* i. 3, 15-19; *Anabasis,* i. ii.; Diodorus xiv. 12, 19-26). Clearchus was a typical Spartan, an able and energetic soldier, but lacking refinement and humanity.

CLEARFIELD, a borough of Clearfield county, Pennsylvania, U.S., 35 mi. N. of Altoona, on the west branch of the Susquehanna river, at an altitude of 1,108 ft., in the central Pennsylvania coal field. It is on federal highway 322; is served by the Baltimore and Ohio, the New York Central and the Pennsylvania railways; and has an airport. The population in 1950 was 9,348; in 1940 it was 9,372; and in 1930, 9,221. It is the county seat, a wholesale distributing centre, and has various manufacturing industries, especially large firebrick, tile and sewer-pipe works, using the fire clay that abounds in the vicinity, metal industries and tanneries. Clearfield was so named because the first white settlers found it already cleared of timber. In 1805 it was chosen as the site for the county seat.

CLEARING HOUSE. When business houses or firms engaged in the same kind of activity have large dealings with each other it is an obvious convenience and economy to establish a mutual institution to enable them to set off their transactions with each other and to clear them, thus making it necessary to pay to each other at agreed times only such balances of account as are revealed by the clearance. Such institutions are called clearing houses, and they have been established in all great commercial nations for many branches of industry. The chief of them are bankers' clearing houses (*see* BANKING) and railway clearing houses.

The London Stock Exchange Clearing House deals with transactions in stock, the clearing being effected by balance-sheets and tickets; the balance of stock to be received or delivered is shown on a balance-sheet sent in by each member, and the items are then cancelled against one another and tickets issued for the balances outstanding. The New York Stock Exchange Clearing House does similar work. The settlements on the Paris Bourse are cleared within the Bourse itself, through the Compagnie des Agents de Change de Paris.

For details concerning clearing house operations in the United States *see* Theodore Gilman, *A Graded Banking System Formed by the Incorporation of Clearing Houses under a Federal Law* (Boston, 1898); Jerome Thralls, *The Clearing House* (1916); Harvey White Magee, *A Treatise on the Law of National and State Banks, Including the Clearing House* (Albany, N.Y., 1921); and Walter Eaton Spahr, *The Clearing and Collection of Checks* (1926).

CLEARWATER, a city on the west coast of Florida, U.S.A., 22 mi. W. of Tampa; the county seat of beautiful Pinellas county, which occupies a small peninsula between the Gulf of Mexico and Old Tampa bay. It is served by the Atlantic Coast Line and the Seaboard Air Line railways. In 1900 the population was 343; in 1930, after annexations of territory brought the area to 17 sq.mi., it was 7,607; in 1950 it was 15,535 by the federal census. Clearwater is in a citrus fruit and market-gardening region, has fisheries of importance, and is a winter resort. A commission-manager form of government was adopted in 1923.

CLEAT, a wedge-shaped piece of wood fastened to ships' masts and elsewhere, to prevent a rope, collar or the like from slipping, or to act as a step; more particularly a piece of wood or metal with double or single horns used for belaying ropes. A "cleat" is also a wedge fastened to a ship's side to catch the shores in a launching cradle or dry dock. "Cleat" is also used in mining for the vertical cleavage-planes of coal. The word is common in various forms to many Teutonic languages, in the sense of a wedge or lump, *cf.* "clod" and "clot."

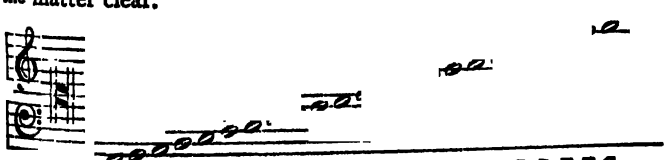
CLEATOR MOOR, a township and civil parish, Cumberland, England, 4¼ mi. S.E. of Whitehaven, served by the L.M.S.R. Pop. (1931) 6,582. The town lies in a coal and iron ore district, and the mines, together with metal works, employ almost the entire population. In consequence, it was severely depressed in the 1930s, unemployment among men being 52.8% in April 1934.

CLEAVERS or **GOOSE-GRASS,** *Galium Aparine* (family Rubiaceae), a common plant in hedges and waste places, with a long, weak, straggling, four-sided, green stem, bearing whorls of six to eight narrow leaves, ½ to 2 in. long, and, like the angles of the stem, rough from the presence of short, stiff, downwardly-pointing, hooked hairs. The small, white, regular flowers are borne, a few together, in axillary clusters, and are followed by the small, hispid, two-celled fruit, which, like the rest of the plant, readily

clings to a rough surface, whence the common name. The plant has a wide distribution throughout the north temperate zone, and is also found in temperate South America.

CLEBSCH, ALFRED (1833–1872), German mathematician, was born at Königsberg, Prussia, on Jan. 19, 1833. He was educated at Königsberg, and in 1858 was appointed to the chair of theoretical mechanics at Carlsruhe Polytechnic. In 1863 Clebsch went to the University of Giessen and in 1868 to Göttingen, where he remained until his death. His attention was turned to algebra and geometry after a study of Salmon's works. Clebsch worked at mathematical physics, the calculus of variation, partial differential equations of the first order, the general theory of curves; he applied Abelian functions to geometry and made use of determinants. In 1867 Clebsch, in conjunction with Carl Neumann, founded the *Mathematische Annalen*. He died of diphtheria on Nov. 7, 1872. Clebsch was the author of *Vorlesungen über Geometrie*, which was edited by Ferdinand Lindemann of Munich in 1875, and of *Theorie d. Elasticität fester Körper* (1862), which was translated into French by Saint-Venant.

CLEBURNE, a city of Texas, U.S.A., 30 mi. S. of Ft. Worth; the county seat of Johnson county. It is served by the Santa Fe railroad and is on federal highway 67 and state highways 171 and 174.



The population was 12,845 in 1950; 10,558 in 1940 (91% native white) and 11,539 in 1930 by the federal census. It is the trade centre of a diversified agricultural, live stock and industrial area and has large railroad shops.

Cleburne was settled in 1867 and incorporated in 1871; it was named after Patrick Ronayne Cleburne (1828–64), a major general of the Confederate army, who was called "the Stonewall of the West."

CLECKHEATON, a parish, West Riding of Yorkshire, England, 5½ mi. S.E. of Bradford, on the L.M.S.R. Pop. (1931) 12,153. The industries comprise the manufacture of woollens, blankets, flannel, wire-card and machinery. Cleckheaton parish is in the Spenborough urban district, pop. (1938) 36,420.

CLEETHORPES, a municipal borough (1936) and watering place in the parts of Lindsey, Lincolnshire, England; 2¼ mi. S.E. of Great Grimsby by a branch of the L.N.E.R. Pop. (1938) 28,730. Area 3.3 sq.mi. It faces eastward to the North sea, but its shore of fine sand, affording good bathing, actually belongs to the estuary of the Humber. The sea-wall forms a pleasant promenade. The suburb of New Clee connects Cleethorpes with Grimsby. The church of the Holy Trinity and St. Mary is principally Norman of various dates, but pre-conquest work appears in the tower. Cleethorpes is greatly favoured as a health resort by people from the midland counties, Lancashire and Yorkshire.

CLEF, in musical notation, is a sign used to indicate the position and pitch of the various notes represented on the stave. Three such signs are now in use,  (or ),  and of which stands for the note *c'*, otherwise middle C on the pianoforte,  for the F below and for the G above. Hence when one of these notes is thus indicated, *e.g.*, or , a key, or clef, is thereby provided from which all the others can be reckoned. A representation of the Great Stave of eleven lines, showing the position on it occupied by each clef sign, will make the matter clear.

F G A B C D E F G A B C D E F G A B C D E F G

From this it will be seen that the F (bass) and G (treble or violin) clefs are the lower and upper five lines respectively and that the C clef (variously known as the tenor or alto clef, according to the particular line on which it is placed) consists of five lines taken from the middle; for it should be explained further that "clef" signifies not only the individual sign but also the group of lines on which it stands, although strictly speaking "stave" is here the more accurate term.

In pianoforte, vocal and most other scores, only the F and G clefs are nowadays used, but the C clef is still retained for the viola and one or two other instruments, the choice of the particular clef used being governed, as it will be understood, by the pitch and compass of the instrument written for, the object aimed at being to include as much of the music as possible within the limits of a five-line stave. It will also be understood that in practice the middle line of the Great Stave is normally omitted, a short additional line known as a leger (or ledger) line being employed to take its place when the intermediate C is required—

It may be noted further that the clef signs as we now know them are simply much modified and conventionalized forms of the letters of the three notes which they stand for—F, C and G. (*See* MUSICAL NOTATION.)

CLEFT PALATE and **HARE-LIP**, in surgery. Cleft palate is a congenital cleavage in the roof of the mouth, and is frequently associated with hare-lip. Both conditions are due to faulty development and may be hereditary. The infant is prevented from sucking, and an operation is necessary. The most favourable time for operating is between the age of two weeks and three months, and if the cleft is closed at this early date, not only are the nutrition and general development of the child greatly improved, but the voice is probably saved from much of the unpleasant tone associated with a defective roof to the mouth. After the cleft in the palate has been effectually dealt with, the hare-lip can be repaired with ease and success.

Hare-lip.—In the hare the splitting of the lip is in the middle line, but in the human subject for developmental reasons it is on one or on both sides of the middle line. Though we are unable to explain why development should miss the mark in formation of the lip and palate, maternal impressions do not have anything to do with it. As a rule, the supposed "fright" comes long after the ninth week of foetal life when the lips are developed. The best time for operating on a hare-lip uncomplicated by cleft palate depends upon circumstances, in a favourable case within the first few days of birth.

CLEISTHENES, the name of two Greek statesmen, (1) of Athens, (2) of Sicyon, of whom the first is far the more important.

(1) CLEISTHENES, the Athenian statesman, was the son of Megacles, the Alcmaeonid, and Agariste, daughter of Cleisthenes of Sicyon. The Alcmaeonidae had been in exile during the Peisistratid tyranny but gained the favour of Delphi by their munificence in the rebuilding of the temple, and their reinstatement was imposed by the oracle upon the Spartan king, Cleomenes (*q.v.*). Aristotle's *Constitution of Athens* treats the alliance of the Peisistratids with Argos, the rival of Sparta in the Peloponnese, as the chief ground for the action of Cleomenes who expelled Hippias in 511–510 B.C., leaving Athens once again at the mercy of the powerful families.

Cleisthenes, on his return, realized that Athens would not tolerate a new tyranny, nor were the other nobles willing to accept him as leader of an oligarchy. It was left for him to "take the people into partnership" as Peisistratus had in a different way done before him. Solon's reforms had failed, primarily because they left unimpaired the power of the great landed nobles. This evil of local influence Peisistratus had concealed by satisfying the nominally sovereign people that in him they had a sufficient representative. It was left to Cleisthenes to adopt the remedy of giving substance to the form of the Solonian constitution. His first attempts roused the aristocrats to a last effort; Isagoras appealed to the

Spartans to come to his aid. Cleisthenes retired on the arrival of a herald from Cleomenes, reviving the old question of the curse. The democrats, however, rose, and after besieging Cleomenes and Isagoras in the Acropolis, let them go under a safe-conduct, and brought back the exiles. We are not told when and how the ascendancy of Cleisthenes came to an end. It is stated that Cleisthenes, hard pressed in the war with Boeotia, Euboea and Sparta (Herod. v. 73), sent ambassadors to ask the help of Persia. Associated as he was with the democrats, the Peisistratid party, this is not improbable. The existence of a strong philo-medic party is clear from the story of the shield after the battle of Marathon, for which the Alcmaeonidae were blamed. (*See* G. B. Grundy, *Great Persian War*, ch. iv.) The gift and withdrawal of Athenian help in the Ionian War (498) is another indication of division of opinion in Athens. Aelian says that he was a victim to his own device of ostracism (*q.v.*); this may perhaps indicate that his political career ended in disgrace, a hypothesis which is explicable on the ground of this attempted Persian alliance.

Cleisthenes realized that the dead-weight which held the democracy down was the influence on politics of the clan unit with its religious associations. Therefore his prime object was to dissociate the clans and the phratries from politics, and to give the democracy a new electoral basis in which old associations and vested interests would become ineffective. His first step was to abolish the four Solonian tribes and create ten new ones. Each of the new tribes was subdivided into "demes" (roughly "townships"); this organization did not, except politically, supersede the system of clans and phratries whose old religious signification remained untouched. The new tribes, however, did not represent local interests. Further, the tribe names were taken from legendary heroes, and, therefore, contributed to the idea of a national unity; even Ajax, the eponym of the tribe Aeantis, though not really Attic, was famous as an ally (Herod. v. 66) and had been adopted as a national hero. Each tribe had its shrine and its particular hero-cult, which, however, was free from local association and the dominance of particular families. This national idea Cleisthenes further emphasized by setting up in the market-place at Athens a statue of each tribal hero.

The next step was the organization of the deme. Within each tribe he grouped demes (*see* below), each of which had its census-list kept by the demarch (local governor), who was elected popularly and held office for one year and presided over meetings affecting local administration and the provision of crews for the state-navy. According to the Aristotelian *Constitution of Athens*, Cleisthenes further divided Attica into three districts, Urban and Suburban, Inland (*Mesogaios*) and Maritime (*Paralia*), each of which was subdivided into ten *trittyes;* each tribe was composed of three trittyes, one in each of the three districts. The demes were arranged in ten groups but the number of demes in a tribe was not uniform. The trittyes might consist of one or several demes and the number of members of a deme varied greatly, though, at first, the division was local, *i.e.*, a deme consisted of its residents, the qualification became hereditary, a man belonging to his father's deme wherever he lived. Hence the distinction between resident demesmen and residents belonging to another deme (ἐγκεκτημένοι). The main purpose of the reform was to do away with the religious qualification of connection with clan or phratry and so facilitate the enfranchisement of new citizens. The artificial arrangement of the trittyes was intended to weaken the authority of the Eupatrid families in the tribes whose widely separated trittyes could not easily be brought under influence.

It has been asked whether we are to believe that Cleisthenes invented the demes. To this the answer is in the negative. The demes were undoubtedly primitive divisions of Attica. The most logical conclusion perhaps is that Cleisthenes, while he did create the demes which Athens itself comprised, did not create the country demes, but merely gave them definition as political divisions. Thus the city itself had six demes in five different tribes, and the other five tribes were represented in the suburbs and the Peiraeus. In the Cleisthenean system there was one great source of danger, namely that the residents in and about Athens must always have had more weight in elections than those in distant demes. Moreover a special class, the new commercial element in the citizenship devised by Solon and fostered by Cleisthenes, soon came to have a preponderating influence in the city and suburbs.

A second problem is the franchise reform of Cleisthenes. Aristotle in the *Politics* (iii. 2. 3 = 1275 b) says that Cleisthenes created new citizens by enrolling in the tribes "many resident aliens and emancipated slaves." But the Aristotelian *Constitution of Athens* asserts that he gave "citizenship to the masses." Μέτοικοι had been encouraged to settle in Athens by Solon and the grant of citizenship had been made to many skilled in trades and handicrafts. The Peisistratids, like the Etruscan dynasty at Rome, naturally favoured this commercial "plebs" as a support against the aristocrats. After their expulsion a revision of the citizen-roll had removed many or all of these as γένει μὴ καθαροί. Cleisthenes restored these and opened the way to citizenship to all satisfactory resident aliens, so strengthening the position of the democracy.

The Boulē (*q.v.*) was reorganized to suit the new tribal arrangement, and was known henceforward as the Council of the Five Hundred, fifty from each tribe, each fifty acting as an executive committee (πρυτάνεις) for one month. The system of ten tribes led in course of time to the construction of boards of ten to deal with military and civil affairs, *e.g.* the Strategi (*see* STRATEGUS), the *Apodektai*, and others. Of these the former cannot be attributed to Cleisthenes, but on the evidence of Androtion it was Cleisthenes who replaced the *Kolakretai*, by the *Apodektai* ("receivers"), who were controllers and auditors of the finance department. *Kolakretai* were very ancient Athenian magistrates; they were again important in the time of Aristophanes (*Wasps*, 693, 724; *Birds*, 1541), and presided over the payment of the dicasts instituted by Pericles. The *Kolakretai* remained in authority over the internal expenses of the Prytaneum. A further change which followed from the new tribal system was the reconstitution of the army; this, however, probably took place about 501 B.C., and cannot be attributed directly to Cleisthenes. It has been said that the deme became the local political unit, replacing the naucrary. But the naucraries still supplied the fleet, and were increased in number from forty-eight to fifty.

The device of ostracism is the final stone in the Cleisthenean structure. An admirable scheme in theory, and, at first, in practice, it deteriorated in the 5th century into a mere party weapon.

Walker in *Camb. Anc. Hist.* vol. iv. ch. vi. *The Reform of Cleisthenes. See* also BOULE; ECCLESIA; OSTRACISM; SOLON.

(2) CLEISTHENES OF SICYON (*c.* 600–570), grandfather of the above, became tyrant of Sicyon as the representative of the conquered Ionian section of the inhabitants. He emphasized the destruction of Dorian predominance by giving ridiculous epithets to their tribal units, which from Hylleis, Dymanes and Pamphyli become Hyatae ("Swine-men"), Choireatae ("Pig-men") and Oneatae ("Ass-men"). He also attacked Dorian Argos, and suppressed the Homeric "rhapsodists" who sang the exploits of Dorian heroes. He championed the cause of the Delphic oracle against the town of Crisa in the Sacred War (*c.* 590). Crisa was destroyed, and Delphi became one of the meeting-places of the Delphic amphictyony (*see* AMPHICTYONY). The Pythian games were re-established with new magnificence, and Cleisthenes won the first chariot race in 582. He founded Pythian games at Sicyon, and built a new Sicyonian treasury at Delphi. His power was so great that when he offered his daughter Agariste in marriage, some of the most prominent Greeks sought the honour, which fell upon Megacles, the Alcmaeonid. The story of the rival wooers with the famous retort, "Hippocleides don't care," is told in Herod. vi. 125; *see* also Herod. v. 67 and Thuc. i. 18.

CLEISTHENES is also the name of an Athenian pilloried by Aristophanes (*Clouds*, 354; *Thesm.* 574) as a fop and a profligate.

CLEITARCHUS, one of the historians of Alexander the Great, possibly a native of Egypt, or at least spent some time at

the court of Ptolemy Lagus. Quintilian (*Instit.* x, i, 74) credits him with more ability than trustworthiness, and Cicero (*Brutus*, ii) accuses him of giving a fictitious account of the death of Themistocles. But his history was popular, and much used by Diodorus Siculus, Quintus Curtius, Justin and Plutarch.

The fragments, about 30 in number, chiefly preserved in Aelian and Strabo, will be found in C. Müller's *Scriptores Rerum Alexandri Magni* (in the Didot *Arrian*, 1846); monographs by C. Raun, *De Clitarcho Diodori, Curtii, Justini auctore* (1868), and F. Reuss, "Hellenistische Beiträge," *Rhein. Mus.*, lxiii, pp. 58–78 (1908).

CLEITHRAL, an architectural term applied to a Greek temple whose roof completely covered it; in contradistinction to hypaethral, applied to one partly or wholly open to the sky.

CLEITOMACHUS, Greek philosopher, was a Carthaginian who came to Athens about the middle of the 2nd century B.C. at the age of 24. He studied principally under Carneades, whose views he adopted and propagated and whom he succeeded as chief of the New Academy in 129 B.C. Of Cleitomachus' works scarcely anything but a few titles are extant. Among these are Περὶ ἐποχῆς (on suspension of judgment) and Περὶ αἱρέσεων (about philosophical sects). Cicero highly commends his works and admits his own debt in the *Academics* to the treatise Περὶ ἐποχῆς. Parts of Cicero's *De Natura* and *De Divinatione* and the treatise *De Fato* are also in the main based upon Cleitomachus.

See E. Wellmann in Ersch and Gruber's *Allgemeine Encyclopädie;* R. Hirzel, *Untersuchungen zu Ciceros philosophischen Schriften,* i (1877); Diog. Laërt., iv, 67–92; Cicero, *Acad. Pr.*, ii, 31, 32, and *Tusc.*, iii, 22.

CLEITOR or CLITOR, a town of ancient Greece, stood in a fertile plain of Arcadia to the south of Mt. Chelmos, not far from a stream of its own name. In the neighbourhood was a fountain, the waters of which were said to deprive those who drank them of the taste for wine. The town was of considerable local importance and its inhabitants combined love of liberty with dominion over neighbours. It fought against Orchomenus in the Theban war and joined the other Arcadian cities in the foundation of Megalopolis. As a member of the Achaean league it was on several occasions the seat of the federal assemblies, and was besieged by the Aetolians in 220 B.C. It coined money till the time of Septimius Severus. Its ruins at Paleopoli are about 3 mi. from a village that preserves the ancient name. The greater part of the walls with several semicircular towers can be clearly made out; also three Doric temples and a small theatre.

CLELAND, WILLIAM (1661?–1689), Scottish Covenanting poet and soldier, son of a gamekeeper, was probably brought up on the marquess of Douglas' estate in Lanarkshire and was educated at St. Andrews university. He joined the army of the Covenanters, was present at Drumclog and fought at Bothwell Bridge. He escaped to Holland, but in 1685 was again in Scotland at the time of the abortive invasion of the earl of Argyll. He escaped once more, to return in 1688 as agent for William of Orange. He was appointed lieutenant colonel of the Cameronian regiment entrusted with the defense of Dunkeld, which they held against the fierce assault of the Highlanders on Aug. 26. This repulse of the Highlanders ended the Jacobite rising, but Cleland fell in the struggle. He wrote *A Collection of Several Poems and Verses* composed upon various occasions (published posthumously, 1697).

See *An Exact Narrative of the Conflict of Dunkeld . . . collected from several officers of the regiment* (1689).

CLEMATIS, a genus of vines and herbs of the crowfoot family (Ranunculaceae), containing 220 species and widely distributed. It is represented in England by *Clematis vitalba,* old-man's-beard or traveller's-joy, a common plant on chalky or light soil. The plants are shrubby climbers with generally compound, opposite leaves, the stalk of which is sensitive to contact like a tendril, becoming twisted round suitable objects and thereby giving support to the plant. The flowers are arranged in axillary or terminal clusters; they have no petals, but white or coloured, often large sepals, and an indefinite number of stamens and carpels. They contain no honey, and are visited by insects for the pollen, which is plentiful. The fruit is a head of achenes, each bearing the long-bearded, persistent style, suggesting the popular name. This feathery style is an important agent in the distribution of the seed by means of the wind. Inclusive of the sections *Viorna* and *Atragene,* which some botanists regard as separate genera, there are about 30 species of *Clematis* native to North America. Of these, the following representatives are more or less cultivated: the woodbine (*C. virginiana*), found from Nova Scotia to Manitoba and southward to Georgia and Tennessee; the western *C. ligusticifolia,* growing from North Dakota and Missouri westward to British Columbia and California; the purple virgin's-bower (*C. verticillaris*), found from Hudson bay to Minnesota and southeastward to Connecticut and Virginia; the scarlet virgin's-bower (*C. texensis*), native to Texas; and the pipestem virgin's-bower (*C. lasiantha*) of California and Oregon.

WILD CLEMATIS, OR TRAVELLER'S-JOY, A CLIMBING PLANT SOMETIMES CULTIVATED TO ADORN GARDEN TRELLISES. THE FEATHERY STYLES OF THE FRUITS (ACHENES) FACILITATE DISPERSAL OF SEED BY THE WIND

Several of the species, especially the large-flowered ones, are favourite garden plants, well adapted for covering trellises or walls or trailing over the ground. Many garden hybrids are popular, among them *C. jackmani* and more than 50 named varieties, of which Gipsyqueen, Ramona and Lady Northcliffe are popular.

See T. Moore and G. Jackman, *The Clematis as a Garden Flower;* J. E. Spingarn in Norman Taylor's *The Garden Dictionary* (Boston, London, 1936).

CLEMENCEAU, GEORGES (1841–1929), French statesman, was born at Mouilleron-en-Pareds, Vendée, on Sept. 28, 1841. He adopted medicine as his profession. Interested in the progressive ideas of John Stuart Mill, he decided to investigate for himself the results of the application to affairs of democratic theory. He therefore embarked for the United States, taking with him Mill's *Auguste Comte and Positivism* to translate into French. He arrived in New York early in 1866 and remained there or in New England for three years, writing descriptions of American postwar conditions to the Paris *Temps* and teaching French in a girls' school at Stamford, Conn. In this way he passed

what he characterized as the three happiest years of his life. In 1869 he returned to Paris and after the revolution of 1870 he was nominated mayor of the 18th arrondissement of Paris (Montmartre). On Feb. 8, 1871, he was elected as a Radical to the National Assembly for the department of the Seine, and voted against the peace preliminaries. The execution of Generals Lecomte and Clément Thomas by their mutinous soldiers on March 18, which he vainly tried to prevent, brought him into collision with the central committee of the National Guard, and they ordered his arrest, but he escaped; he was accused, however, by various witnesses, at the subsequent trial (Nov. 29), of not having intervened when he might have done, and though he was cleared of this charge it led to a duel, for his share in which he was prosecuted and sentenced to a fine and a fortnight's imprisonment.

Meanwhile, on March 20, 1871, he had introduced in the National Assembly at Versailles, on behalf of his Radical colleagues, the bill establishing a Paris municipal council of 80 members; but he was not returned himself at the elections. He tried with the other Paris mayors to mediate between Versailles and the hôtel de ville, but failed, and accordingly resigned his mayoralty and his seat in the assembly, and temporarily gave up politics; but he was elected to the Paris municipal council on July 23, 1871, for the Clignancourt *quartier*, and retained his seat till 1876, passing through the offices of secretary and vice-president, and becoming president in 1875. In 1876 he stood again for the Chamber of Deputies, and was elected for the 18th arrondissement. He joined the extreme Left, and his energy and mordant eloquence speedily made him the leader of the Radical section. In 1877, after the *Seize mai* (*see* FRANCE: *History*), he took a leading part in resisting the anti-republican policy of which the *Seize mai* incident was a symptom, and in 1879 demanded the indictment of the Broglie ministry. In 1880 he started his newspaper, *La Justice*, which became the principal organ of Parisian Radicalism; and from this time onwards throughout Grévy's presidency his reputation as a political critic, and as a destroyer of ministries who yet would not take office himself, rapidly grew. He led the extreme Left in the Chamber. He was an active opponent of Jules Ferry's colonial policy and of the Opportunist party, and in 1885 his use of the Tongking disaster principally determined the fall of the Ferry cabinet. At the elections of 1885 he was returned both for his old seat in Paris and for the Var, selecting the latter. Refusing to form a ministry to replace the one he had overthrown, he supported the Right in keeping Freycinet in power in 1886, and was responsible for the inclusion of Gen. Boulanger in the Freycinet cabinet as war minister. When Boulanger (*q.v.*) showed his real colours, Clemenceau became a vigorous opponent of the Boulangist movement, though the Radical press and a section of the party continued to patronize the general.

By his exposure of the Wilson scandal (*see* GRÉVY) Clemenceau contributed to Grévy's resignation of the presidency in 1887, having declined Grévy's request that he should himself form a cabinet on the downfall of that of Rouvier; and he was primarily responsible, by advising his followers to vote neither for Floquet, Ferry nor Freycinet, for the election of an "outsider" as president in Carnot. But the split in the Radical party over Boulangism weakened his hands, and his relations with Cornelius Herz in the Panama affair involved him in the general suspicion. However, though he remained the leading spokesman of French Radicalism, his hostility to the Russian alliance so increased his unpopularity that in the election for 1893 he was defeated for the Chamber. Clemenceau now confined his political activities to journalism, his career being further overclouded by the Dreyfus case, in which he was an active supporter of Zola and an opponent of the anti-Semitic and Nationalist campaign. In 1900 he withdrew from *La Justice* to found a weekly review, *Le Bloc*, which lasted until March 1902. On April 6, 1902, he was elected senator for the Var, although he had previously continually demanded the suppression of the Senate. He sat with the Socialist Radicals, and vigorously supported the Combes ministry. In June 1903 he undertook the direction of the journal *L'Aurore*, which he had founded. In it he led the campaign for the revision of the Dreyfus affair, and for the separation of Church and State.

In March 1906 the fall of the Rouvier ministry, owing to the riots provoked by the inventories of church property, at last brought Clemenceau to power as minister of the interior in the Sarrien cabinet. The strike of miners in the Pas de Calais after the disaster at Courrières, leading to the threat of disorder on May 1, 1906, induced him to employ the military; and his attitude in the matter alienated the Socialist party, from which he definitely broke in his notable reply in the chamber to Jean Jaurès in June 1906. This speech marked him out as the "strong man" of the day in French politics; and when the Sarrien ministry resigned in October, he became premier. During 1907 and 1908 the new *entente* with England was cemented, and France played a great part in European politics, in spite of difficulties with Germany and attacks by the Socialist party in connection with Morocco (*see* FRANCE: *History*). But on July 20, 1909, Clemenceau was defeated in a discussion in the chamber on the state of the navy, and was succeeded as premier by Briand, with a reconstructed cabinet.

Two years later Clemenceau entered the Senate and became a member of its commissions for foreign affairs and the army. He could have had no better position for surveying European fluctuations and German activities; or for inquiry into the real condition of French armaments—this last his dominant concern. Convinced that Germany meant war, he was haunted by the fear that again France might be caught unprepared. The Senate, however, gave little opportunity for sounding the alarm. Accordingly, on May 5, 1913, appeared a new daily paper, *L'Homme Libre*, its editor—Georges Clemenceau. In its pages he waged daily battle for security and liberty. Though *L'Homme Libre* dealt every day with home politics and social problems, it returned always to the terrible theme of the German menace.

In the spring of 1913 the question of restoring the three years' term of conscript service suddenly arose. Clemenceau took an impassioned part in the debates on armaments. Then came Aug. 1914 and the World War. *L'Homme Libre* soon suffered at the hands of the Censor for Clemenceau's plain speaking. The whole youth of France must be mobilized. He denounced the shirkers, demanded technical efficiency, and attacked all incompetency, red tape, inadequate munition factories, with their shortage of guns and rifles, and badly-run hospitals. He made war in short, upon all who failed to realize that this was a conflict of supplies and organization, and upon every kind of apathy and feebleness. The result was that in Sept. 1914 *L'Homme Libre* was suppressed. Two days later, however, it reappeared as *L'Homme Enchaîné*, but wore its fetters lightly. For three months there was a daily struggle with the Censor. For some time not a week passed without articles being mutilated, but Clemenceau won and excisions became rare. Meanwhile in the Senate, Clemenceau agitated for more and still more guns, munitions, soldiers, for a judicious use of the available man-power and for a better equipped and better organized medical service.

But above all he strove to create the indomitable and desperate "will to victory." He was supported by other members of the army and foreign affairs commission, like Chéron, Doumer, Humbert, Berenger. The war dragged on; weariness, slackness and pacifism began to appear. Clemenceau was the first to draw public attention to that growing peril and it was at a public debate in the Senate on July 22, 1917, that he made his famous attack on Malvy, who had been Minister of the Interior since 1914. Clemenceau declared that Malvy had not treated revolutionaries with a firm enough hand. Malvy's justification was that he desired to "gain the confidence of the working-man"; but Clemenceau retorted that there was no comparison between those working-men who were loyally doing their duty to their country and a number of abject "defeatists."

Four months later Clemenceau came into power. He had never sought office and he knew that his task meant victory or death. When Clemenceau became premier the situation was miserable. The *moral* at the front was bad, and at home even worse. Resources were nearly at an end, and no solution whatever could be discerned. Poincaré realized that of all men Clemenceau was

the impersonation of the idea of war to the death. In his new Government Clemenceau himself took the portfolio of minister of war. He was 76 years of age when he formed his "victory cabinet" on Nov. 16, 1917, and thenceforward till Nov. 11, 1918, Clemenceau did in fact concentrate on war only. He made it clear that France was bent on absolute victory and would brook no half-measures. Those who spoke of wavering or yielding were immediately silenced; any one who obstructed the path to victory was ruthlessly removed. By these means Clemenceau restored the nation's self-confidence, and with it the conviction that its martyrdom would not be in vain. In March 1918 the Anglo-French line was broken through; Clemenceau joined in organizing the unity of command with Foch at the head. In May came the disaster of the Chemin des Dames; the French troops were driven back on the Marne, while the commander-in-chief was criticised. Three months later Clemenceau made Foch Marshal of France. During that long year of ceaseless effort Clemenceau's resolution remained unshaken. On Nov. 8, 1918, Erzberger was in the train of the Commander-in-chief of the allied armies. On the 11th the guns roared for the last time; the nightmare was over.

From Nov. 11, 1918, to June 28, 1919, Clemenceau devoted himself to the international settlement. The Peace of Versailles was in preparation, and this necessitated strenuous days of work and delicate negotiations. Up till now Clemenceau had merely had to contend with his enemies; now his task was to reconcile the interests of France with those of her friends. He defended her cause with enthusiasm and conviction, forcing his view alternatively on Lloyd George and President Wilson. Meanwhile Germany was disarming, and Clemenceau took care to supervise that disarmament. But the French parliament began to grow restless, for it saw itself put to one side in the peace negotiations. It therefore no longer regarded Clemenceau as indispensable. The great patriot, who was anxious to finish the work he had begun, did his best to smooth matters over. Momentous problems had to be solved; demobilization had to be faced, a general election was looming ahead, and the questions of Alsace-Lorraine and the liquidation of war stocks had to be settled. Clemenceau decided to deal simultaneously with these questions as of equal importance.

Peace was signed on June 28, and on Nov. 11 the new chamber was elected. Clemenceau counted on its support; for he believed that its members, many of them ex-soldiers, would have profited by the lesson of the war. Although he never stood as a candidate it is certain that he would have been ready to give the last years of his life by taking Poincaré's place at the Elysée, so that outside and above the changing Governments, he could have secured continuity in political action by a strict application of the 1919 treaties.

Poincaré left the Elysée but Deschanel was elected President of the French republic. And without doubt the Chambers had voted according to their hearts. Clemenceau had saved his country, but members could not forgive the fact that he had excluded them from the final work for victory. During the war he had undoubtedly worked alone; he felt that large assemblies were not made for action. Probably he would have admitted the commissions to the deliberations on the Treaty of Versailles if diplomatic obstacles had not intervened to prevent it. Clemenceau had also to face the hostility, not only of the clerical party of the Right who suspected him of indifference to the Vatican, but also that of the extreme Left, who were alienated by what they considered to be his militarism. Clemenceau thus met the fate which overtook other war ministers, and on Jan. 20, 1920, his cabinet fell. Millerand being summoned to office. He had earned the gratitude of his country and, returning to his beloved books, might well have sought repose; instead he sailed for India. After his journey he returned to Paris and to his books.

But it now appeared that the United States was endeavouring to dissociate itself from European affairs. Clemenceau was now 81 years old, but he sailed at once for America at the end of 1922. From town to town he carried the message of France to the citizens of the U.S. He had no official mission, for he had neither asked anything nor received anything from the French Government. His progress was none the less triumphant. Once more he returned to Paris but not to rest. By the end of 1925 he was already writing two books; one on philosophy, *Au Soir de la Pensée* (1927), English translation, *In the Evening of my Thought* (1929), and the other on Demosthenes, *Demosthène* (1926, Eng. trans. by C. M. Thompson, 1926). He was at work upon his memoirs, *Grandeurs et Misères d'un Victoire* (1930), when he died in Paris on Nov. 24, 1929. (J. Mt.)

CLEMENCÍN, DIEGO (1765–1834), Spanish scholar and politician, was born at Murcia, and educated there at the Colegio de San Fulgencio. In 1807 he became editor of the *Gaceta de Madrid*, and in the following year was condemned to death by Murat for publishing a patriotic article; he fled to Cadiz, and under the Junta Central held various posts from which he was dismissed by the reactionary government of 1814. During the liberal régime (1820–23) Clemencín took office as colonial minister, was exiled till 1827, and in 1833 published the first volume of his edition (1833–39) of *Don Quixote*.

CLEMENS, SAMUEL L.: *see* TWAIN, MARK.

CLEMENT, the name of 14 popes and 2 antipopes.

CLEMENT I, Saint, generally known as Clement of Rome (Clemens Romanus), was one of the "Apostolic Fathers." In the earliest list of the bishops of Rome given by Irenaeus, he appears as the third successor of St. Peter (Peter, Linus, Anacletus, Clement). According to Eusebius, his period of office began in the 12th year of Domitian's reign (A.D. 92) and ended in the third year of Trajan's (A.D. 101). Tertullian states that Clement was consecrated by St. Peter himself. Origen's identification of him with the Clement mentioned by St. Paul (Phil. iv, 3) lacks corroboration, and the sources which represent him as a member of the Flavian imperial family are untrustworthy. His feast occurs in the Roman calendar on Nov. 23, and he is commemorated among the martyrs in the canon of the Mass.

He is best known by his only surviving work, the *Epistle to the Church of Corinth*, which is one of the most important documents of the subapostolic age. The letter was occasioned by a dispute in the church of Corinth which had led to the ejection of several presbyters. While it does not contain Clement's name, the tradition which attributes it to him is primitive and universal. Internal evidence (references to the persecution of Domitian) and the testimony of Hegesippus indicate that it was written *c.* A.D. 96. Though the letter does not expressly assert the primacy of the Roman church, it is noteworthy that, in the earliest document outside the canon which can be securely dated, that church is found acting as a peacemaker in the affairs of a church in Greece. The writer moreover employs a tone which is unmistakably authoritative. Nothing is known of the cause of the troubles at Corinth, and the deposition of the presbyters is regarded by Clement as high-handed and unjustifiable. He objects against it the hierarchical principle on which the Christian ministry is based. His argument sets forth in essence the doctrine of the apostolic succession, and it is in this that the permanent interest of the letter lies. The penultimate section of the letter contains a long liturgical prayer which is most probably that used at Rome in the Eucharist at that period. Another interesting feature of the letter is the extensive use which the author makes of the Septuagint for purposes of illustration, indicating that his background was that of Hellenistic Judaism. Clement's epistle was widely read in Christian antiquity and at one time formed part of the New Testament canon in Egypt and Syria. The high regard in which Clement was held by the primitive church is indicated by the number of apocryphal writings attached to his name. (*See* CLEMENTINE LITERATURE.)

BIBLIOGRAPHY.—A convenient edition will be found in J. B. Lightfoot, *The Apostolic Fathers*, vol. i, with English trans. (London, 1890); *see* also W. K. Lowther Clarke (ed.), *The First Epistle of Clement to the Corinthians* (London, 1937); and J. Quasten, *The Beginnings of Patristic Literature*, vol. i of *Patrology*, 4 vol. (Utrecht and Westminster, Md., 1950); this last work contains a comprehensive bibliography.

CLEMENT II (Suidger), pope from 1046 to 1047, belonged to a noble Saxon family. He became bishop of Bamberg and chancellor to the emperor Henry III, who elevated him to the papacy.

Clement was elected pope on Dec. 24, 1046. His short pontificate was only signalized by the convocation of a council in which decrees were enacted against simony. He died on Oct. 9, 1047.

CLEMENT III (Paolo Scolari), pope from 1187 to 1191, a Roman and cardinal bishop of Palestrina, was elected pope on Dec. 19, 1187. In October of that year Jerusalem had fallen to Saladin, and Clement urged on the princes of the west to undertake the third crusade. Apart, however, from the capture of Acre, the results were disappointing. In Italy the marriage of King Henry of the Romans with Constance of Sicily threatened to unite south Italy to the German crown. This Clement tried to avert by enfeoffing Count Tancred of Lecce with Sicily, but he died before the results of his policy became apparent. One of his permanent acts was the removal of the Scottish church from the jurisdiction of York (1188). Thenceforward the Scottish church was dependent directly on Rome.

CLEMENT IV (Gui Foulques), pope from 1265 to 1268, son of a lawyer, was born at St. Gilles-sur-Rhône. He became a valued legal adviser of Louis IX of France and after the death of his wife took orders. In 1257 he was made bishop of Le Puy, in 1259 archbishop of Narbonne and in 1261 cardinal bishop of Sabina. He was appointed legate in England in 1263 and before his return was elected pope at Perugia on Feb. 5, 1265. Determined like his predecessors to extirpate the Hohenstaufen dynasty from Italy, he invested the avaricious Charles of Anjou with the kingdom of Sicily but subsequently came into conflict with him after the death of Manfred in Feb. 1266. When Conradin, the last of the Hohenstaufen, appeared in Italy, the pope excommunicated him and his supporters. Clement died at Viterbo on Nov. 29, 1268, leaving a name unsullied by nepotism.

CLEMENT V (Bertrand de Got), pope from 1305 to 1314, was born at Villandraut (Gironde) of a noble Gascon family. After studying law at Orléans and Bologna he became canon of Bordeaux, then vicar-general to his brother (the archbishop of Lyons), bishop of Comminges in 1295 and archbishop of Bordeaux in 1299. On June 5, 1305, he was chosen to succeed Benedict XI, as a compromise candidate known to be acceptable to Philip IV of France.

A weak man, who suffered throughout his pontificate from a chronic illness, Clement yielded to the constant pressure of French interests. Thus at the instance of Philip IV his crowning took place at Lyons, and after it, instead of making for Rome, he retired to Gascony. Finally, in March 1309, he settled with his court at Avignon where the papacy was to remain for the next 70 years, the period of the so-called Babylonian captivity. Clement chose Avignon because, as the property of the Angevine rulers of Naples, it was not dependent on the French crown. Also it was surrounded by the papal county of Venaissin and offered easy egress to the sea. He seems never to have abandoned his intention of moving to Rome as soon as the political situation allowed, and he made no plans for a permanent residence at Avignon, contenting himself with the Dominican priory in that city.

In Dec. 1305 Clement created nine French cardinals, and further creations in 1310 and 1312 ensured French domination of the sacred college and the succession of a French pope. Throughout his pontificate he was blackmailed by Philip IV's threat of reopening the posthumous trial of Boniface VIII. The price Clement had to pay for the suspension of these proceedings was the annulment of all Boniface's acts against French interests, the absolution of Guillaume de Nogaret, the royal councillor who had organized the outrage of Anagni, and finally the canonization of Celestine V (May 1313). The most glaring example of Clement's subservience to the French king was his suppression of the Knights Templars. The attack on the order was launched by the king in 1307, apparently for financial reasons (they were the bankers of the French crown). Clement issued the bull of suppression on April 3, 1312, at the Council of Vienne, which was summoned to give the act a judicial appearance. Although a later bull (May 2) assigned the property of the Templars to the Hospitallers, the chief beneficiary in France was the king. The weakness of Clement's position in France did not prevent him from pursuing active and independent policies elsewhere. He intervened in the dispute over the Hungarian succession. He disposed of the imperial crown in favour of Henry of Luxemburg (1312), and prosecuted a successful war against Venice in order to recover the papal rights over Ferrara.

Under Clement the centralization of ecclesiastical government was carried a stage further. Papal reservations were extended to new classes of benefice, and papal nomination became the most frequent method of episcopal appointment. A jurist himself, Clement added an important section (the *Clementines*) to the *Corpus Iuris Canonici*. As a scholar and patron of scholars, he gave university status to the schools of Orléans and Perugia and founded chairs of oriental languages at Paris, Bologna, Oxford and Salamanca. At his death on April 20, 1314, he left the papal treasury impoverished by his extravagant bequests.

BIBLIOGRAPHY.—The authoritative work is by G. Mollat, *Les Papes d'Avignon*, 9th ed. (Paris, 1949), which contains comprehensive bibliographies. *See* also A. Eitel, *Der Kirchenstaat unter Klemens V* (Berlin, 1907); G. Lizerand, *Clement V et Philippe IV le Bel* (Paris, 1910); E. Mueller, *Das Konzil von Wien, 1311–1312* (Münster, 1934).

CLEMENT VI (Pierre Roger), pope from 1342 to 1352, was born at Maumont, Limousin, in 1291, joined the Benedictines as a boy, studied at Paris and became successively prior of St. Baudil, abbot of Fécamp, bishop of Arras, chancellor of France, archbishop of Sens and archbishop of Rouen. He was made cardinal priest of Sti Nereo ed Achilleo and administrator of the bishopric of Avignon by Benedict XII in 1338, and four years later succeeded him as pope (May 7, 1342). Clement continued the struggle of his predecessors with the emperor Louis the Bavarian, excommunicating him in April 1346, and directing the election of Charles of Luxemburg, who received general recognition after the death of Louis in 1347, and put an end to the schism which had long divided Germany. Clement carried on fruitless negotiations for church unity with the Armenians and with the Greek emperor, John Cantacuzenus. He tried to end the Hundred Years' War between England and France but secured only a temporary truce. He excommunicated Casimir of Poland for marital infidelity and forced him to do penance. He successfully resisted encroachments on ecclesiastical jurisdiction by the kings of England. He purchased Avignon from Queen Joanna of Naples and considerably enlarged the papal palace. These undertakings, together with the upkeep of a splendid court, the open-handed patronage of artists and scholars and large loans to the French crown, bankrupted the papal treasury and forced Clement to resort to increasingly onerous taxation. After the austere days of Benedict XII, the flood of reservations and expectancies recommenced. The machinery of tax collection was improved by the grouping of local churches into collectories. Clement's fiscality led to a growing body of complaint (expressed in England in the Statute of Provisors) and bequeathed an insuperable problem to his successors. He died on Dec. 6, 1352.

Faucon, *Prêts faits aux rois de France par Clement VI etc.* (Bibliothèque de l'École des Chartes, xi, 1879); D. Colombe, *Le Palais des papes d'Avignon* (Paris, 1927).

CLEMENT VII (Giulio de' Medici), pope from 1523 to 1534, was the son of Giuliano de' Medici, assassinated in the Pazzi conspiracy at Florence. After the death of Lorenzo, Giulio in 1494 went into exile; but, on Giovanni's restoration to power, returned to Florence, of which he was made archbishop by his cousin, Pope Leo X, a special dispensation being granted on account of his illegitimate birth, followed by a formal declaration of the fact that his parents had been secretly married and that he was therefore legitimate. In 1513 he was made cardinal and during the pontificate of Leo had practically the whole papal policy in his hands. On the death of Adrian VI he was chosen pope (Nov. 18, 1523). It soon became clear, however, that Clement was only a good second in command, for though he was cultured and economical without being avaricious, he was essentially a man of narrow outlook and interests. Instead of bending his mind to the problem of the Reformation, he subordinated the cause of

Catholicism to his interests as an Italian prince and a Medici; and even in purely secular affairs his timidity and indecision prevented him from pursuing a consistent policy.

His accession at once brought about a political change in favour of France. He wavered between the emperor and Francis I, concluding a treaty of alliance with the French king, and then after the defeat of Pavia making his peace with Charles (April 1, 1525), but breaking it again by countenancing Girolamo Morone's League of Freedom, which aimed to assert Italian independence. On the betrayal of this conspiracy Clement made a fresh submission to the emperor, only to follow this, a year later, by the Holy League of Cognac with Francis I (May 22, 1526). Then followed the imperial invasion of Italy and Bourbon's sack of Rome (May 1527). The pope himself was besieged and compelled to ransom himself with 400,000 scudi and to promise to convene a general council to deal with Lutheranism. After the treaty of Cambrai on Aug. 3, 1529, Charles met Clement at Bologna and received from him the imperial crown and the iron crown of Lombardy, but the pope for some time exercised his temporal power in subservience to the emperor. Clement was now mainly occupied in urging Charles to arrest the progress of the Reformation in Germany and in efforts to elude the emperor's demand for a general council, which Clement feared lest the mode of his election and his legitimacy should be raised. Clement's fear of displeasing Charles V, as well as his solicitude for canonical principles, made him temporize in face of Henry VIII's demand for the nullification of his marriage with Catherine until, losing patience, Henry carried the English church into schism. Clement died on Sept. 25, 1534.

Crabitès, *Clement VII and Henry VIII* (London, Toronto, 1936); R. Mols, "Clément VII" in *Dictionnaire d'histoire et de géographie ecclésiastique*, vol. xii, with bibliography (Paris, 1953).

CLEMENT VII (Robert of Geneva), antipope from 1378 to 1394, was son of count Amadeus III of Geneva. Bishop of Thérouanne (1361) and archbishop of Cambrai (1368), he was created cardinal by Gregory XI in 1371 and entrusted with the military mission of restoring the papal states. The ferocity of his Breton and English mercenaries, above all the massacre of Cesena (1377), made the name of the "cardinal of Geneva" a byword throughout Italy.

In 1378 he took part in the confused election of Urban VI. After the French cardinals had seceded and announced that Urban's election was irregular, Robert of Geneva was elected pope at Fondi on Sept. 20, 1378. He was crowned the same day, as Clement VII. Thus originated the Great Schism of the West. The schism rapidly took political lines, Clement being supported by Queen Joanna of Naples, Charles V of France, Scotland, Castile, Aragon, Navarre, the Latin enclaves in the east and the count of Flanders. In Italy however the tide quickly turned against Clement and in May 1379 he took ship and returned to Avignon, taking the cardinals of his allegiance with him. To wrest Rome from his rival, he induced Louis, duke of Anjou, to take up his cause, promising him a kingdom to be carved out of the states of the church, coupled with the expectation of succeeding Joanna in Naples. Louis however proved a disappointing generalissimo and the only lasting outcome of this bargain was the passing of Naples to Louis's son in 1384. In his last years Clement worked hard to head off the University of Paris which was openly advocating a general council as the only means of ending the schism. He died on Sept. 16, 1394, asserting to the last his claim to be the rightful pope.

(C. H. LE.)

CLEMENT VIII (Ippolito Aldobrandini), pope from 1592 to 1605, was born at Fano on Feb. 24, 1536. He became a jurist and in 1585 was made a cardinal. On Jan. 30, 1592, he was elected pope to succeed Innocent IX. To him fell the unspectacular but vitally important task of consolidating the ground won by the reforms of the Council of Trent. He had published a revised text of the Vulgate (1592) which remained the official edition until the 20th century, and in turn revised and edited the principal liturgical books: the pontifical (1596), the breviary (1602) and the missal (1604). A new edition of the index was compiled in 1593. He tackled the dispute between the Jesuits and the Dominicans over the rival theories of grace and free will by summoning the contestants to Rome (1594), where the debate still continued after his death in 1605. By so protracting the contest, he allowed it to lose some of its urgency, with the result that Paul V was able to terminate it in 1605 without any decision being reached. In diplomacy, Clement was determined to free the papacy from the shackles of Spanish domination; he granted absolution to Henry IV in 1595, so dissociating the papacy from the militant Catholic party in France and Spain, and this new policy had a spectacular success when peace was concluded between the two countries at Vervins in 1598. The new independence won by the papacy was revealed by the ease with which Clement, upon the failure of the line of Este, claimed the reversion of Ferrara and reincorporated it into the states of the church (1598). In ending the war in France, Clement had hoped to weaken the Protestant powers who had profited by its continuance, but his direct intervention into English affairs was not so successful. First the archpriest controversy (1598), then, after the death of Elizabeth I, the persecution that followed the Gunpowder plot, seriously weakened the position of Catholics in England. Yet, by his death (March 5, 1605), Clement could claim that, internally and diplomatically, the papacy was much strengthened, though the history of the 17th century might suggest that, in curbing the power of Spain and raising that of France, the papacy had but exchanged one master for another.

CLEMENT VIII (Aegidius Muñoz), antipope from 1425 to July 26, 1429, was a canon at Barcelona until elected by three cardinals created by the antipope Benedict XIII. Clement was recognized by Alphonso V of Aragon, who was hostile to Pope Martin V because of the latter's opposition to his claims to Naples. When Alphonso and Martin became reconciled, Clement abdicated and spent his last years as bishop of Majorca. He died on Dec. 28, 1446.

CLEMENT IX (Giulio Rospigliosi), pope from 1667 to 1669, was born on Jan. 28, 1600, and after a career in the papal chancery was archbishop of Tarsus and nuncio in Spain before being made a cardinal and secretary of state by Alexander VII. During his long career he had made himself acceptable to both France and Spain, and his considerable experience made him the choice also of the independent party among the cardinals to succeed Alexander on June 20, 1667. He proved no match for the diplomatic abilities of Hugues de Lionne, Louis XIV's ambassador at the Vatican, and the peace of Aix-la-Chapelle (1668) between France and Spain which he was instrumental in concluding secured for France all it desired, while the peace of Clement IX which secured the return of the expelled nuns to Port Royal (1669) was designed by Lionne equally in the interests of the French monarchy. In return for these concessions, Clement had hoped to win French support against the Turks in Crete, but French assistance to the Venetian garrison was slight as well as insincere, and the island was captured in 1669. Clement died soon afterward (Dec. 9, 1669).

CLEMENT X (Emilio Altieri), pope from 1670 to 1676, was born in Rome on July 13, 1590, and after a long career in the papal diplomatic service became pope at the age of 79 (April 29, 1670). The breathing space it was hoped such an appointment would bring did not materialize, for relations with France steadily deteriorated, and the outbreak in 1673 of the long controversy over the regalia (*see* INNOCENT XI) called for the services of a strong, not a stop-gap, pope. Clement died on July 22, 1676.

CLEMENT XI (Giovanni Francesco Albani), pope from 1700 to 1721, was born in Urbino on July 22, 1649, and after filling various important offices in the curia became pope on Nov. 23, 1700, succeeding Innocent XII. His private life and his adminis-

tration were blameless, but it was his misfortune to reign in troublous times. In the War of the Spanish Succession he first supported Philip V but was compelled by the emperor under the threat of invasion to change sides in 1709. In the peace of Utrecht he was ignored; Sardinia and Sicily, Parma and Piacenza were disposed of without regard to papal claims. When he quarrelled with the duke of Savoy and revoked his investiture right in Sicily (1715), his interdict was treated with contempt. Clement supported the Jesuit position when the controversy over the Five Propositions was revived in France, and in 1713 issued the bull *Unigenitus*, condemning 101 Jansenistic propositions. (*See* JANSENISM and QUESNEL, PASQUIER.) He also forbade missionaries in China to "accommodate" their teachings to pagan notions in order to win converts. He died on March 19, 1721.

CLEMENT XII (Lorenzo Corsini), pope from 1730 to 1740, was born at Florence on April 7, 1652. His entire career was spent at Rome in the papal administration, and he became a cardinal in 1706. He was elected pope on July 12, 1730, at the age of 78, to succeed Benedict XIII. Despite old age and ill health, he took an active part in the administration, and in internal matters of routine proved to be competent and efficient. His diplomatic activities, however, were not so successful; his endeavour to remain neutral in the War of the Polish Succession (1733–37) led only to the papal states being invaded by the troops of both sides, while his assistance of the emperor against the Turks did not prevent the surrender of Belgrade in 1739. Coming of a very rich family, Clement was, both as cardinal and pope, a great patron of learning and the arts. He died on Feb. 6, 1740.

CLEMENT XIII (Carlo della Torre Rezzonico), pope from 1758 to 1769, was born in Venice on March 7, 1693, and after a career in the curia was made cardinal in 1737 and bishop of Padua in 1743. He became pope on July 6, 1758, at a time when the papacy, after a century of diminishing prestige as an international power, was once again being attacked by reforming movements in the national churches as the defender of obscurantism and the ally of the traditionalist orders, especially the Jesuits. These considerations, however, left Clement quite unmoved, and he took up the cause of the Jesuits, to whom he was indebted for his election, without reservation. He brought about a final crisis with the Bourbon monarchies by an attempt to reassert the temporal power over Parma (1768) and, when he refused to give way to their united demands, found himself faced with the seizure of Avignon, Benevento and Ponte Corvo and an almost universal call for the suppression of the Jesuits. He was in no position to resist and had consented to call a consistory just before his death on Feb. 2, 1769. His papacy was one of almost unmitigated disaster.

CLEMENT XIV (Giovanni Vincenzo Antonio, otherwise Lorenzo, Ganganelli), pope from 1769 to 1774, was born near Rimini on Oct. 31, 1705. He joined the Franciscans (when he adopted his father's name of Lorenzo) and, after serving on the Inquisition and establishing his reputation as a scholar, was made a cardinal by Clement XIII. He was not, however, in agreement with the extreme policy of opposition to the Bourbons pursued by that pope and so remained in the background during the disputes over the Jesuits. He seemed, therefore, to offer a compromise to the conclave in 1769 between the insistence of the Bourbons that the next pope must promise before election to agree to the suppression of the Jesuits, and the supporters of the policy of Clement XIII who formed a majority among the cardinals. Ganganelli promised at least that he would in the last resort agree to the suppression, but hoped to avoid this necessity by a policy of conciliation on all other issues. In these circumstances, and faced with the critical situation left by Clement XIII, he was elected pope without opposition on May 18, 1769. He immediately put his new policy of conciliation into action and achieved some success, but the intransigence of the Bourbon demands and the continued indiscretions of the Jesuits themselves together brought all his efforts to nought. After long consideration, he decided that the Jesuits must be sacrificed, and on July 21, 1773, he signed the brief *Dominus ac Redemptor* dissolving the order (*see* JESUS, SOCIETY OF). All the other events of his papacy are dwarfed by this decision, for which, at the time and since, he has been both criticized and defended. The immediate result was the restoration to the Holy See of the seized territories and a general improvement in the relations between the papacy and the temporal powers, and it is difficult to discover any alternative policy that would not have led to instant and utter disaster. Yet the fact remains that, with the suppression, the prestige of the papacy reached its lowest point since the time of the Reformation. Clement himself died not long afterward, on Sept. 22, 1774. Contemporary suspicions of foul play are probably not well founded.

See J. Cretinau-Joly, *Clément XIV et les Jésuites* (Paris, 1847) and A. Theiner, *Histoire du pontificat de Clément XIV* (Fr. trans., Paris, 1852), which deal with Clement's part in the suppression of the Jesuits from different points of view. The question was partly reopened by O. Montevenosi "Un pontificato da reabilitare. Il papa Clemente XIV" in *Archivi* (Rome, 1941). (I. F. B.)

CLÉMENT, FRANÇOIS (1714–1793), French historian, was born at Bèze, near Dijon. He became a Benedictine and wrote vol. xi and xii of the *Histoire littéraire de la France* and edited (with Dom Brial) vol. xii and xiii of the *Recueil des historiens des Gauls et de la France*. The king appointed him to the committee for the publication of charters and other historical documents. Of his revision of the *Art de vérifier les dates*, ed. by Dom Clémencet (1750), three volumes with indexes appeared from 1783 to 1792. Clément died at Paris on March 29, 1793.

CLÉMENT, JACQUES (1567–1589), murderer of the French king Henry III, was born at Sorbon in the Ardennes and became a Dominican friar. With his mind apparently unhinged by religious fanaticism and inspired by members of the Catholic League, who were urging him to save the kingdom, he obtained letters for the king and, on July 31, 1589, left Paris, which the king was besieging, for the royal headquarters at Saint Cloud. Next day, while Henry was reading the letters, Clément mortally wounded him with a dagger that he had concealed under his cloak. Clément was killed on the spot by Henry's attendants.

See P. de Vaissière, *De quelques assassins* (Paris, 1912).

CLÉMENTEL, ÉTIENNE (1862–1936), French politician, was born on March 29, 1862, at Riom and educated there. He was elected a deputy in 1898 and became minister for the colonies in Rouvier's cabinet in 1905, afterwards occupying ministerial posts in departments where his knowledge of economics could find full play, the ministries of agriculture, colonies, finance, public works and marine. His collaboration was particularly valuable in organizing the supply of raw materials for the allied armies during World War I. By effecting the agreement for establishment of the inter-allied wheat executive with Walter Runciman in Nov. 1916, Clémentel helped to tide over a difficult situation. The creation of the inter-allied maritime transport council was due in great part to his energy, for, as early as Aug. 1917, he had occupied himself with drawing up a general inventory of his own country's requirements, an initiative quickly followed by the allied governments. After the armistice, Clémentel was chosen "Président fondateur" of the International Chamber of Commerce. He was elected senator for Puy de Dôme in 1918. His work at the London Conference of July 1924, which he attended as minister of finance in the Herriot cabinet, was greatly appreciated. He resigned office as minister of finance on April 3, 1925, on the ground of a difference with Herriot on the question of a fresh issue of notes by the Bank of France. In 1927 he was president of the finance committee of the Senate and also became a member of the committee on trade barriers of the International Chamber of Commerce. Among his writings may be mentioned: *L'Âme celtique* (1899) and *Un drame économique* (1914).

CLEMENTI, MUZIO (1752–1832), Italian pianist and composer, was born at Rome where his father was a jeweller. At nine he was appointed organist of a church and at fourteen he had written a mass which was performed in public. About 1766 Peter Beckford, cousin of the author of *Vathek*, brought Clementi to England, where his success both as composer and pianist was rapid and brilliant. In 1777 he was for some time employed as conductor of the Italian opera, but he soon afterwards left London for Paris. Here also his concerts were crowded by enthusiastic audiences, and the same success accompanied him on a tour about the year 1780 to southern Germany and Austria. At Vienna, which he visited between 1781 and 1782, he was received with high honour by the emperor Joseph II, in whose presence he met Mozart, and fought a kind of musical duel with him.

In May 1782 Clementi returned to London, where for the next twelve years he continued his lucrative occupations of fashionable teacher and performer at the concerts of the aristocracy. He took shares in the pianoforte business of a firm which went bankrupt in 1800. He then established a pianoforte and music business of his own, under the name of Clementi & Co. which was very successful. Other members were added to the firm, including Collard and Davis, and it was ultimately taken over by Collard.

Among his pupils on the pianoforte during this period may be mentioned John Field, the composer of the celebrated *Nocturnes*. In his company, Clementi paid, in 1804, a visit to Paris, Vienna, St. Petersburg (Leningrad), Berlin and other cities. While he was in Berlin, Meyerbeer became one of his pupils. He also revisited his own country, after an absence of more than 30 years. In 1810 Clementi returned to London, but refused to play again in public, devoting the remainder of his life to composition. Several symphonies belong to this period but none was published.

Of Clementi's playing in his youth, Moscheles wrote that it was "marked by a most beautiful *legato*, a supple touch in lively passages, and a most unfailing technique." Mozart may be said to have closed the old and Clementi to have founded the newer school of technique on the piano. Among Clementi's compositions the most remarkable are 60 sonatas for pianoforte, and the great collection of *Études* called *Gradus ad Parnassum*.

CLEMENTINE LITERATURE, the name generally given to the writings which at one time or another were fathered upon Pope Clement I (*q.v.*), commonly called Clemens Romanus, who was early regarded as a disciple of St. Peter. Chief among them are: (1) the so-called Second Epistle; (2) two Epistles on Virginity; (3) the *Homilies* and *Recognitions*, with which may be classed the *Epistle of Clement to James;* (4) the *Apostolical Constitutions* (*q.v.*); and (5) five epistles forming part of the Forged Decretals (*see* DECRETALS). The present article deals mainly with the third group, to which the title "Clementine literature" is usually confined, owing to the stress laid upon it in the famous Tubingen reconstruction of primitive Christianity, in which it played a leading part; but later criticism has lowered its importance as its true date and historical relations have been progressively ascertained. (1) and (2) became "Clementine" only by chance, but (3) was so originally by literary device or fiction, the cause at work also in (4) and (5). But while in all cases the suggestion of Clement's authorship came ultimately from his prestige as writer of the genuine *Epistle of Clement* (*see* CLEMENT I), both (3) and (4) were due to this idea as operative on Syrian soil; (5) is a secondary formation based on (3) as known to the west.

(1) *The Second Epistle of Clement.*—This is really the earliest extant Christian homily (*see* APOSTOLIC FATHERS). Its theme is the duty of Christian repentance, with a view to obedience to Christ's precepts as the true confession and homage which He requires. Its special charge is "Preserve the flesh pure and the seal (*i.e.*, baptism) unstained" (viii, 6). The homily was considered a part of Scripture in the Syriac Church and is found in the Codex Alexandrinus. It was most probably composed before A.D. 150 at Corinth (*see* F. X. Funk and G. Kruger), but Rome and Alexandria have also been proposed as the place of origin about 170.

(2) *The Two Epistles to Virgins, i.e.*, to Christian celibates of both sexes. These are known in their entirety only in Syriac, and were first published by J. J. Wetstein (1752), who held them genuine. This view is now usually discredited. There is no trace of their use in the west. Their Syrian origin is manifest, the more so that in the Syriac ms. they are appended to the New Testament, like the better-known epistles of Clement in the Codex Alexandrinus. It is now definitely established, however, that they were written originally, not in Syriac, but in Greek. Special occasion for such hortatory letters may be discerned in their polemic against intimate relations between ascetics of opposite sex, implied to exist among its readers, in contrast to usage in the writer's own locality. Now we know that spiritual unions, prompted originally by high-strung Christian idealism as to a religious fellowship transcending the law of nature in relation to sex, did exist between persons living under vows of celibacy during the 3rd century in particular. On the basis of internal evidence, therefore, the letters were most probably composed not later than the middle of the 3rd century, and they furnish precious information on the early stages of Christian asceticism.

(3*a*) *The Epistle of Clement to James* (the Lord's brother). This was originally part of (3*b*), in connection with which its origin and date are discussed. But as known to the west through Rufinus' Latin version, it was quoted as genuine throughout the middle ages. It became the starting point of the most momentous and gigantic of mediaeval forgeries, the Isidorian Decretals, where it stands at the head of the pontifical letters, extended to more than twice its original length.

(3*b*) *The Homilies and Recognitions.*—"The two chief extant Clementine writings, differing considerably in some respects in doctrine, are both evidently the outcome of a peculiar speculative type of Judaistic Christianity, for which the most characteristic name of Christ was 'the true Prophet.' The framework of both is a narrative purporting to be written by Clement (of Rome) to St. James, the Lord's brother, describing at the beginning his own conversion and the circumstances of his first acquaintance with St. Peter, and then a long sucession of incidents accompanying St. Peter's discourses and disputations, leading up to a romantic recognition of Clement's father, mother and two brothers, from whom he had been separated since childhood. The problems discussed under this fictitious guise are with rare exceptions fundamental problems for every age; and, whatever may be thought of the positions maintained, the discussions are hardly ever feeble or trivial. Regarded simply as mirroring the past, few, if any, remains of Christian antiquity present us with so vivid a picture of the working of men's minds under the influence of the new leaven which had entered into the world" (F. J. A. Hort, *Clem. Recog.*, p. xiv). Recent criticism builds on the principle, which emerges alike from the external and internal evidence that both writings used a common basis or parent document. Toward the determination of its nature, origin and antecedents, a number of important contributions have been made, beginning with the pioneer works of F. J. A. Hort and Dr. Hans Waitz; but there is as yet no general agreement on many points. The Clementines are still a major problem in early Christian literature.

External Evidence.—Whether Origen refers to the Clementine writings is a moot question, but Eusebius of Caesarea clearly mentions them in his *Eccl. Hist.*, iii, 38: "Certain men have quite lately brought forward as written by him (Clement) other verbose and lengthy writings, containing dialogues of Peter, forsooth, and Apion, whereof not the slightest mention is to be found among the ancients, for they do not even preserve in purity the stamp of the Apostolic orthodoxy." Apion, the Alexandrine grammarian and foe of Judaism, whose criticism was answered by Josephus, appears in this character both in *Homilies* and *Recognitions*, though mainly in the former (iv, 6–vii, 5). Thus Eusebius implies (1) a spurious Clementine work containing matter found also in our *Homilies* at any rate; and (2) its quite recent origin. Next we note that an extract in the *Philocalia* of Origen is introduced as follows: "Yea, and Clement the Roman, a disciple of Peter the Apostle, after using words in harmony with these on the present problem, in conversation with his father at Laodicea in the *Circuits*, speaks a very necessary word touching this matter" (astrological divination). The extract answers to *Recognitions*, x, 10–13, but it is absent from our *Homilies*. Here we observe that (1) the extract agrees this time with *Recognitions*, not with *Homilies;* (2) its framework is that of the Clementine romance found in both; (3) the tenth and last book of *Recognitions* is here parallel to book xiv of a work called *Circuits* (*Periodoi*). This last point leads on naturally to the witness of Epiphanius (*c.* 375), who, speaking of Ebionites or Judaizing Christians of various sorts, and particularly the Essene type, says (*Haer.* xxx, 15) that "they use certain other books likewise, to wit, the so-called *Circuits* of Peter, which were written by the hand of Clement. . . . In the *Circuits*, then, they adapted the whole to their own views, representing Peter falsely in many ways, as that he was daily baptized for the sake of purification, as these also do; and they say that he likewise abstained from animal food and meat, as they themselves also do." Now all the points here noted in the *Circuits* can be traced in our *Homilies* and *Recognitions*, though toned down in different degrees. The witness of the Arianizing *Opus Imperfectum in Matthaeum* (*c.* 400) is in general similar. Its usual form of citation is "Peter in Clement" (*apud Clementem*), and points to "Clement" as a brief title for the Clementine *Periodoi*.

It has been needful to cite so much of the evidence proving that our *Homilies* and *Recognitions* are both recensions of a common basis, at first known as the *Circuits of Peter* and later by titles

connecting it rather with Clement, its ostensible author, because it affords data also for the historical problems touching (*a*) the contents and origin of the primary Clementine work, and (*b*) the conditions under which our extant recensions of it arose.

(*a*) *The Circuits of Peter,* as defined on the one hand by the epistle of Clement to James originally prefixed to it and by patristic evidence, and on the other by the common element in our *Homilies* and *Recognitions,* may be conceived as follows. It contained accounts of Peter's teachings and discussions at various points on a route beginning at Caesarea, and extending northward along the coastlands of Syria as far as Antioch. During this tour he meets with persons of typically erroneous views, which it was presumably the aim of the work to refute in the interests of true Christianity, conceived as the final form of divine revelation—a revelation given through true prophecy embodied in a succession of persons, the chief of whom were Moses and the prophet whom Moses foretold, Jesus the Christ. The prime exponent of the spurious religion is Simon Magus. A second protagonist of error, this time of Gentile philosophic criticism directed against fundamental Judaism, is Apion, the notorious anti-Jewish Alexandrine grammarian of Peter's day; while the role of upholder of astrological fatalism (*Genesis*) is played by Faustus, father of Clement, with whom Peter and Clement debate at Laodicea. Finally, all this is already embedded in a setting determined by the romance of Clement and his lost relatives, "recognition" of whom forms the denouement of the story.

There is no reason to doubt that such, roughly speaking, were the contents of the Clementine work to which Eusebius alludes slightingly, in connection with that section of it which had to his eye least verisimilitude, viz., the dialogues between Peter and Apion. Now Eusebius believed the work to have been of recent and suspicious origin. The opinion of Eusebius and the prevailing doctrinal tone—in part gnostic—of the contents, as known to us, point to a date not much later than the first quarter of the third century. The standpoint is that of the peculiar Judaizing Christianity due to persistence among Christians of the tendencies known among pre-Christian Jews as Essene. The Essenes, while clinging to what they held to be original Mosaism, yet conceived and practised their ancestral faith in ways which showed distinct traces of syncretism, or the operation of influences foreign to Judaism proper. They thus occupied an ambiguous position on the borders of Judaism. Similarly Christian Essenism was syncretist in spirit, as we see from its best-known representatives, the Elchasaites, of whom we first hear about 220, when a certain Alcibiades of Apamea in Syria (about 60 mi. south of Antioch) brought to Rome the *Book of Helxai*—the manifesto of their distinctive message (Hippol., *Philos.* ix, 13)—and again some 20 years later, when Origen refers to one of their leaders as having lately arrived at Caesarea (Euseb. vi, 38).

The *Periodoi* or *Circuits* must not be thought of as strictly Elchasaite, since it knew no baptism distinct from the ordinary Christian one. It seems rather to represent a later and modified Essene Christianity, already half Catholic, such as would suit a date after 250, in keeping with Eusebius' evidence. Confirmation of such a date is afforded by the silence of the Syrian *Didascalia,* itself perhaps dating from about 220, as to any visit of Simon Magus of Caesarea, in contrast to the reference in its later form, the *Apostolical Constitutions* (*c.* 350–400), which is plainly coloured (vi, 9) by the Clementine story. On the other hand, the *Didascalia* seems to have been evoked partly by Judaizing propaganda in north Syria. If, then, it helps to date the *Periodoi* as after 220, it may also suggest as place of origin one of the large cities lying south of Antioch, say Laodicea (itself on the coast about 30 mi. from Apamea), where the Clementine story reaches its climax. The intimacy of local knowledge touching this region implied in the narrative common to *Homilies* and *Recognitions* is notable, and tells against an origin for the *Periodoi* outside Syria (*e.g.,* in Rome, as Hans Waitz and A. Harnack hold, but J. B. Lightfoot disproves, *Clem.* i, 55 f., 64,100, *cf.* Hort, p. 131). Further, though the curtain even in it fell on Peter at Antioch itself (our one complete ms. of the *Homilies* is proved by the *Epitome,* based on the *Homilies,* to be here abridged), the interest of the story culminates at Laodicea.

If we assume, then, that the common source of our extant Clementines arose in Syria, perhaps, *c.* 230, had it also a written source or sources which we can trace? Most recent scholars believe that the common source (*Grundschrift*) was itself a compilation, the chief elements of which were the "Preachings (*Kerymata*) of Peter," the *Actus Vercellenses,* an *Apologia Judaica* and a pagan romance. The first source at least seems implied by the epistle of Peter to James and its appended adjuration, prefixed in our mss. to the *Homilies* along with the *Epistle of Clement to James.* Thus the later work aimed at superseding the earlier, much as Photius suggests (*see* above). It was, then, to these "Preachings of Peter" that the most Ebionite features, and especially the anti-Pauline allusions under the guise of Simon still inhering in the *Periodoi* (as implied by *Homilies* in particular), originally belonged. The fact, however, that these were not more completely suppressed in the later work, proves that it, too, arose in circles of kindred, though largely modified, Judaeo-Christian sentiment (cf. *Homilies,* vii, *e.g.,* ch. 8). The differences of standpoint may be due not only to lapse of time, and the emergence of new problems on the horizon of Syrian Christianity generally, but also to change in locality and in the degree of Greek culture represented by the two works. The "Preachings of Peter" may be as early as the first third of the second century.

If the home of the *Periodoi* was the region of the Syrian Laodicea, we can readily explain most of its characteristics. Photius refers to the "excellences of its language and its learning"; while Waitz describes the aim and spirit of its contents as those of an apology for Christianity against heresy and paganism, in the widest sense of the word, written in order to win over both Jews (cf. *Recognitions,* i, 53–70) and pagans, but mainly the latter. In particular it had in view persons of culture, as most apt to be swayed by the philosophical tendencies in the sphere of religion prevalent in that age, the age of neo-Platonism. It was in fact designed for propaganda among religious seekers in a time of singular religious restlessness and varied inquiry, and, above all, for use by catechumens (cf. *Ep. Clem.* 2, 13) in the earlier stages of their preparation for Christian baptism. To such its romantic setting would be specially adapted, as falling in with the literary habits and tastes of the period; while its doctrinal peculiarities would least give offence in a work of the aim and character just described.

(*b*) That the *Periodoi* was a longer work than either our *Homilies* or *Recognitions* is practically certain; and its mere bulk may well, as Hort suggests, have been a chief cause of the change of form. Yet *Homilies* and *Recognitions* are abridgements made on different principles and convey rather different impressions their readers. The *Homilies* care most for doctrine, especially philosophical doctrine, and seem to transpose very freely for doctrinal purposes; the *Recognitions* care most for the story, as a means of religious edification, and have preserved the general framework much more nearly. They arose in different circles; indeed, save the compiler of the text represented by the Syriac ms. of A.D. 411 (who gives a selection of discourses from the *Homilies* after *Recognitions,* iii), not a single ancient writer shows a knowledge of both books in any form. *Homilies* was a sort of second edition, made largely in the spirit of its original and perhaps in much the same locality. The *Recognitions,* in both recensions, as is shown by the fact that it was read in the original with general admiration not only by Rufinus but also by others in the west, was more Catholic in tone.

The recensions of the two works, as we know them, were most probably made in Syria in the second half of the fourth century, and they were used in part at least in this period to serve the interests of Aryan propaganda.

The Clementine literature throws light upon a very obscure phase of Christian development, that of Judaeo-Christianity, and proves that it embraced more intermediate types, between Ebionism proper and Catholicism, than has generally been realized. Incidentally, too, its successive forms illustrate many matters of belief and usage among Syrian Christians generally in the 3rd and 4th centuries, notably their apologetic and catechetical needs and methods. The romance to which it owed much of its popular appeal, became,

through the medium of Rufinus' Latin, the parent of the late mediaeval legend of Faust, and so the ancestor of a famous type in modern literature.

But the Clementine literature no longer has the great doctrinal significance once attached to it by the Tübingen school. It still offers us, however, a fullness of instructive entertainment, as E. Schwartz observes, and is certainly more interesting than what many modern scholars have written about it.

CLEMENT OF ALEXANDRIA (*Clemens Alexandrinus*) was probably born about A.D. 150 of heathen parents in Athens. The earliest writer after himself who gives us any information with regard to him is Eusebius (d. 370). The only points on which his works now extant inform us are his date and his instructors. In the *Stromateis* ("Miscellanies"), while attempting to show that the Jewish scriptures were older than any writings of the Greeks, he invariably brings down his dates to the death of Commodus (192), a circumstance which at once suggests that he wrote in the reign of the emperor Severus, from 193 to 211 (see *Strom.* lib. i cap. xxi. 140). We know nothing of his conversion except that it occurred, for his writings show a singularly minute acquaintance with the ceremonies of pagan religion, and there are indications that he himself had been initiated into some of the mysteries (*Protrept.* cap. ii. sec. 14). He attained the position of presbyter in the church of Alexandria (Eus. *H.E.* vi. 11, and Jerome, *De Vir. Ill.* 38), and became perhaps the assistant, and certainly the successor of Pantaenus in the catechetical school of that place. Among his pupils were Origen (Eus. *H.E.* vi. 7) and Alexander, bishop of Jerusalem (Eus. *H.E.* vi. 14). How long he continued in Alexandria, and when and where he died, are all matters of pure conjecture.

Clement occupies a profoundly interesting position in the history of Christianity. He is the first to bring all the culture of the Greeks and all the speculations of the Christian heretics to bear on the exposition of Christian truth. The list of Greek authors from whom he quoted occupies upwards of 14 of the 4to. pages in Fabricius's *Bibliotheca Graeca*. He is at home alike in the epic and the lyric, the tragic and the comic poets, his knowledge of the prose writers is very extensive, and he made a special study of the philosophers. Equally minute is his knowledge of the systems of the Christian heretics; and it is plain that he not merely read but thought deeply on the questions which the civilization of the Greeks and the various writings of poets, philosophers and heretics raised. It was, however, in the Scriptures, which he held contained the revelation of God's wisdom to men, that he was most deeply read, yet, notwithstanding the great biblical knowledge evidenced by his works, the modern theologian is disappointed to find in them very little of what he deems distinctively Christian. In fact Clement regarded Christianity as a philosophy. The ancient philosophers sought through their philosophy to attain to a nobler and holier life, and this also was the aim of Christianity. The difference between the two, in Clement's judgment, was that the Greek philosophers had only glimpses of the truth, that they attained only to fragments of the truth, while Christianity revealed in Christ the absolute and perfect truth. All the stages of the world's history were therefore preparations leading up to this full revelation, and God's care was not confined to the Hebrews alone. The worship of the heavenly bodies, for instance, was given to man at an early stage that he might rise from a contemplation of these sublime objects to the worship of the Creator. Greek philosophy in particular was the preparation of the Greeks for Christ. It was the schoolmaster or pedagogue to lead them to Christ. Clement varies in his statement how Plato got his wisdom or his fragments of the Reason; sometimes he thinks that they came direct from God, like all good things, but he is also fond of maintaining that many of Plato's best thoughts were borrowed from the Hebrew prophets; and he makes the same statement in regard to the wisdom of the other philosophers. But however this may be, Christ was the end to which all that was true in philosophies pointed. Christ himself was the Logos, the Reason. God the Father was ineffable. The Son alone can manifest Him fully. He is the Reason that pervades the universe, that brings out all goodness, that guides all good men. It was through possessing somewhat of this Reason that the philosophers attained to any truth and goodness; but in Christians he dwells more fully and guides them through all the perplexities of life. Photius, probably on a careless reading of Clement, argued that he could not have believed in a real incarnation. But the words of Clement are quite precise and their meaning indisputable. The real difficulty attaches not to the Second Person, but to the First. The Father in Clement's mind becomes the Absolute of the philosophers, not the Father of the Gospel at all. He believed in a personal Son of God who was the Reason and Wisdom of God; and he believed that this Son of God really became incarnate though he speaks of him almost invariably as the Word, and attaches little value to his human nature. The object of his incarnation and death was to free man from sin, to lead him into the path of wisdom, and thus in the end elevate him to the position of a god. But man's salvation was to be gradual. It began with faith, passed from that to love, and ended in full and complete knowledge. There could be no faith without knowledge; but the knowledge is imperfect, and the Christian has to do many things in simple obedience without knowing the reason. He has to move upwards continually until he at length does nothing that is evil and knows fully the reason and object of what he does. He thus becomes the true Gnostic, but he can become the true Gnostic only by contemplation and by the practice of what is right. He has to free himself from the power of passion; he has to give up all thoughts of pleasure; he must prefer goodness in the midst of torture to evil with unlimited pleasure; he must resist the temptations of the body, keeping it under strict control, and with the eye of the soul undimmed by corporeal wants and impulses, contemplate God the supreme good, and live a life according to reason. In other words, he must strive after likeness to God as he reveals himself in his Reason or in Christ. Clement thus looks entirely at the enlightened moral elevation to which Christianity raises man. He believed that Christ instructed men before he came into the world, and he therefore viewed heathenism with kindly eye. He was also favourable to the pursuit of all kinds of knowledge. All enlightenment tended to lead up to the truths of Christianity, and hence knowledge of every kind not evil was its handmaid. Clement had at the same time a strong belief in evolution or development. The world went through various stages in preparation for Christianity. The man goes through various stages before he can reach Christian perfection. And Clement conceived that this development took place not merely in this life, but in the future through successive grades. The Jew and the heathen had the gospel preached to them in the world below by Christ and His apostles, and Christians will have to pass through processes of purification and trial after death before they reach knowledge and perfect bliss.

Eusebius and Jerome give lists of the works which Clement left behind him. (1) Πρὸς Ἕλληνας λόγος ὁ προτρεπτικός, *A Hortatory Address to the Greeks;* (2) Ὁ Παιδαγωγός; *The Tutor* in three books; (3) Στρωματεῖς ("patchwork"), or *Miscellanies*, in 8 books; (4) Τίς ὁ σωζόμενος πλούσιος, *Who is the rich man that is saved?* (5) Ὑποτυπώσεις, *Adumbrations or Outlines* in 8 books; treatises on (6) *The Passover*, (7) *Fasting*, (8) *Slander*, (9) *Patience*, "for the newly baptised"; and (10) *On the Rule of the Church*, "for those who Judaise." Of these the first four have come down to us complete or nearly so. The *Address to the Greeks* contains an attack on the crudities and immoralities in the stories told of heathen deities, with an argument that the great thinkers and poets of Greece had recognized the unit and spirituality of the divine Being, and that fuller light had been revealed through the Hebrew prophets. In the *Paedogogus*, he explains how before the incarnation Christ

was gradually leading mankind to the Truth, and then explains how the Christian following the Logic or Reason ought to behave in the various circumstances of life. The contents of the *Miscellanies*, as the title indicates are very varied. Sometimes they discuss chronology, sometimes philosophy, sometimes poetry; but one object runs through all, to show what the true Christian Gnostic is, and what is his relation to philosophy. The tract *Who is the rich man that is saved?* is an admirable exposition of Mark x. 17–31. Clement argues that wealth, if rightly used, is not unchristian. Of the remaining books mentioned by Eusebius, we know that the *Adumbrations* was a short commentary on all the books of Scripture, including some apocryphal books; and we have two fragments of the book on the *Passover*. Of the others nothing is known. We have also fragments of two treatises, on *Providence* and on the *Soul*, not named by Eusebius.

Patrick, *Clement of Alexandria* (1914). W. R. Inge, "Alexandrian Theology," in J. Hastings, *Encyclopaedia of Religion and Ethics* (1908), gives an excellent summary account of the Alexandrine School. The standard edition of the collected works is O. Stählin, *Clemens Alexandrinus* (Leipzig, 1905). We have a valuable separate edition of *Miscellanies*, bk. vii., ed. F. J. A. Hort and J. B. Mayor (1902), and of the tract on Wealth by P. M. Barnard, *Texts and Studies*, vol. 2 (Cambridge, 1897). *See* also B. F. Westcott, "Clement of Alexandria" *Murray's Dictionary of Christian Biography* (1911).

CLEMENTS, FREDERIC EDWARD (1874–1945), American plant oecologist, was born in Lincoln, Neb., Sept. 16, 1874. He graduated in 1894 at the University of Nebraska from which in 1898 he received the degree of doctor of philosophy. From 1894 to 1906 he was instructor and associate professor of botany and in 1906–07 he was professor of plant physiology, at the University of Nebraska. He was professor of botany and head of the botanical department in the University of Minnesota from 1907 to 1917 when he was made associate in charge of oecological research in the Carnegie Institution of Washington. He conducted extensive investigations in oecology, palaeo-oecology, experimental evolution and climatology. Among his published works are: *The Phytogeography of Nebraska*, with Roscoe Pound (1898, 2nd ed., 1900); *Development and Structure of Vegetation* (1904); *Research Methods in Ecology* (1906); *Plant Physiology and Ecology* (1907); *Minnesota Mushrooms* (1910); *Rocky Mountain Flowers*, with Edith Clements (1913), *Plant Succession* (1916); *Plant Indicators* (1920); *The Phylogenetic Method in Taxonomy*, with H. M. Hall (1923); *Plant Succession and Indicators* (1927); and *Flower Families and Ancestors* (1927).

CLEOBULUS, one of the Seven Sages of Greece, a native and tyrant of Lindus in Rhodes. He was distinguished for his strength and his handsome person, for the wisdom of his sayings, the acuteness of his riddles, and the beauty of his lyric poetry. Diogenes Laërtius quotes a letter in which Cleobulus invites Solon to take refuge with him against Peisistratus; and this would imply that he was alive in 560 B.C. He is said to have held advanced views as to female education, and he was the father of the wise Cleobuline, whose riddles were not less famous than his own (Diogenes Laërtius, i. 89–93).

See F. G. Mullach, *Fragmenta Philosophorum Graecorum*, i.

CLEOMENES, the name of three Spartan kings of the Agiad line (Κλεομένης).

Cleomenes I. was the son of Anaxandridas, whom he succeeded about 520 B.C. His chief exploit was his crushing victory near Tiryns over the Argives, some 6,000 of whom he burned to death in a sacred grove to which they had fled for refuge (Herodotus vi. 76–82). This secured for Sparta the undisputed hegemony of the Peloponnese. Cleomenes' interposition in the politics of central Greece was less successful. In 510 he marched to Athens with a Spartan force to aid in expelling the peisistratidae, and subsequently returned to support the oligarchical party, led by Isagoras, against Cleisthenes (*q.v.*). He expelled 700 families and transferred the government from the council to 300 of the oligarchs, but being blockaded in the Acropolis was forced to capitulate. On his return home he collected a large force, with the intention of making Isagoras despot of Athens, but the opposition of the Corinthian allies, and of his colleague, Demaratus, caused the expedition to break up after reaching Eleusis (Herod. v. 64–76; Aristotle, *Ath. Pol.* 19, 20). In 491 he went to Aegina to punish the island for its submission to Darius, but the intrigues of his colleague once again rendered his mission abortive. In revenge Cleomenes accused Demaratus of illegitimacy and secured his deposition in favour of Leotychides (Herod. vi. 50–73). But when it was discovered that he had bribed the Delphian priestess to substantiate his charge he was himself obliged to flee; he went first to Thessaly and then to Arcadia, where he attempted to foment an anti-Spartan rising. About 488 B.C. he was recalled, but shortly afterwards, in a fit of madness, he committed suicide (Herod. vi. 74, 75). Cleomenes seems to have received scant justice at the hands of Herodotus or his informants, and Pausanias (iii. 3, 4) does little more than condense Herodotus' narrative. In spite of some failures, largely due to Demaratus' jealousy, Cleomenes strengthened Sparta in the position, won during his father's reign, of champion and leader of the Hellenic race; it was to him, for example, that the Ionian cities of Asia Minor first applied for aid in their revolt against Persia (Herod. v. 49–51).

The chief ancient authority is Herodotus (v. and vi.). *See* E. M. Walker, *Cambridge Ancient History*, vol. iv., ch. vi., § 1, 4, 5, and ch. viii., § 8). For chronology *see* J. Wells, *Journal of Hellenic Studies* (1905), p. 193 ff., who assigns the Argive expedition to the outset of the reign, whereas nearly all historians have dated it in or about 495 B.C.

Cleomenes II. was the son of Cleombrotus I., brother and successor of Agesipolis II. Nothing is recorded of his reign save the fact that it lasted for nearly 61 years (370–309 B.C.).

Cleomenes III., the son and successor of Leonidas II., reigned about 235–219 B.C. He made a determined attempt to reform the social condition of Sparta along the lines laid down by Agis IV., whose widow, Agiatis, he married; at the same time he aimed at restoring Sparta's hegemony in the Peloponnese. After twice defeating the forces of the Achaean league in Arcadia, near Mount Lycaeum and at Leuctra, he strengthened his position by assassinating four of the ephors, abolishing the ephorate, which had usurped the supreme power, and banishing some 80 of the leading oligarchs. The authority of the council was also curtailed, and a new board of magistrates, the *patronomi*, became the chief officers of state. He appointed his own brother, Eucleidas, as his colleague in succession to the Eurypontid Archidamus, who had been murdered. His social reforms included a redistribution of land, the remission of debts, the restoration of the old system of training ἀγωγή and the admission of picked *perioeci* (*q.v.*) into the citizen body. As a general Cleomenes did much to revive Sparta's old prestige. He defeated the Achaeans at Dyme, made himself master of Argos, and was eventually joined by Corinth, Phlius, Epidaurus and other cities. But Aratus, whose jealousy could not brook to see a Spartan at the head of the Achaean league, called in Antigonus Doson, of Macedonia, and Cleomenes, after conducting successful expeditions to Megalopolis and Argos, was finally defeated at Sellasia, to the north of Sparta, in 222 or 221 B.C. He took refuge at Alexandria with Ptolemy Euergetes, but was arrested by his successor, Ptolemy Philopator, on a charge of conspiracy. Escaping from prison he tried to raise a revolt, but the attempt failed, and to avoid capture he put an end to his life. Both as general and as politician Cleomenes was one of Sparta's greatest men, and with him perished her last hope of recovering her ancient supremacy in Greece.

See Polybius ii. 45–70, v. 35–39, viii. 1; Plutarch, *Cleomenes; Aratus*, 35–46; *Philopoemen*, 5, 6; Pausanias ii. 9; Holm, *History of Greece*, iv. cc. 10, 15. (M. N. T.)

CLEON (d. 422 B.C.), Athenian politician during the Peloponnesian War, was the son of Cleaenetus, from whom he inherited a tannery. He was the first prominent representative of the commercial class in Athenian politics. He came into notice first as an opponent of Pericles, and in his opposition somewhat curiously found himself acting in concert with the aristocrats, who equally hated and feared Pericles. In 430, when the city was devastated by the plague, Cleon headed the opposition to the Periclean régime. Pericles was accused of maladministration of public money, with the result that he was actually found guilty

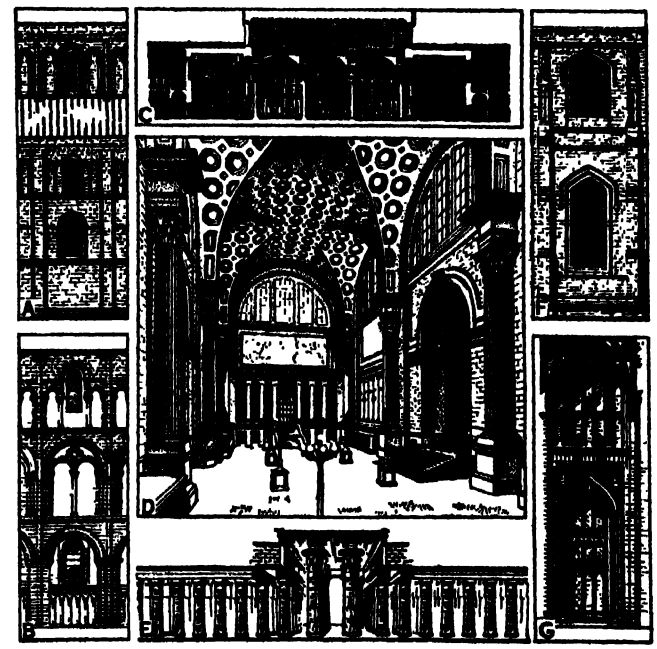
though he was re-elected in 429. The death of Pericles (429) left the field clear for Cleon. Hitherto he had only been a vigorous opposition speaker, a critic and accuser of state officials. He now came forward as the champion and leader of the democracy, and, was for some years undoubtedly the foremost man in Athens. He was gifted with natural eloquence and a powerful voice, and knew how to work upon the feelings of the people. He became the leader of the war party in opposition to Nicias and the moderates, who favoured a cautious strategy and an early peace.

In 427 when Mytilene, which had revolted, fell, Cleon proposed that all its citizens should be put to death, and the women and children enslaved. His policy was to hold down the empire, now a "tyranny," by naked force. His decree was passed, but rescinded next day, in time to save Mytilene.

In 425 he, when the Spartans were blockaded in Sphacteria, brought about the rejection of the terms offered by Sparta, and in the hope of securing a peace which should restore Athens' land-empire. He then reached the summit of his fame by capturing the Spartans on the island (*see* PYLOS). Much of the credit of this success, the most notable which the Athenians won during the Archidamian War, was due to the military skill of his colleague Demosthenes; but it was due to Cleon's determination that the Ecclesia sent out the additional force which was needed. About this time Cleon doubled the tribute of the allies (*see* DELIAN LEAGUE) and raised the pay of the Athenian jurors from two to three obols (Schol. Ar. *Wasps* 88). In 422, after the close of the armistice, Cleon, who was eager to continue the war, went to recover Thrace from Brasidas, but, after capturing several cities, was taken by surprise at Amphipolis, defeated and killed. With his death, the peace party at Athens gained power, and the Peace of Nicias was concluded. (*See* PELOPONNESIAN WAR).

Cleon is represented by Aristophanes and Thucydides in an extremely unfavourable light. But neither can be considered an unprejudiced witness. Aristophanes was not only opposed to Cleon's political programme, but bore him a personal grudge, having been prosecuted by the demagogue after the production of his *Babylonians*. Moreover, his treatment of Socrates should put us on our guard against accepting his evidence against Cleon. Thucydides had been exiled by a decree proposed by Cleon after the loss of Amphipolis.

West and D. B. Meritt, "Cleon's Amphipolitan Campaign" (*American Journal of Archaeology* xxix. 1925).



CLEOPATRA, the regular name of the queens of Egypt, in the Ptolemaic dynasty after Cleopatra, daughter of the Seleucid Antiochus the Great, wife of Ptolemy V., Epiphanes. The best-known was the daughter of Ptolemy XI, Auletes, born 69 (or 68) B.C. At the age of 17 she became queen of Egypt jointly with her younger brother Ptolemy Dionysus, whose wife, in accordance with Egyptian custom, she was to become. A few years later, deprived of all royal authority, she withdrew into Syria, and prepared to recover her rights by force of arms. At this juncture Julius Caesar followed Pompey into Egypt. The personal fascinations of Cleopatra induced him to undertake a war on her behalf, in which Ptolemy lost his life, and she was replaced on the throne with a younger brother, of whom, however, she soon rid herself by poison. In Rome she lived openly with Caesar as his mistress, until his assassination, when, aware of her unpopularity, she returned to Egypt. Subsequently she became the ally and mistress of Mark Antony (*see* ANTONIUS). Their connection was highly unpopular at Rome, and Octavian (*see* AUGUSTUS) declared war upon them and defeated them at Actium (31 B.C.). Cleopatra escaped to Alexandria, where Antony joined her. Having no prospect of ultimate success, she accepted Octavian's proposal that she should assassinate Antony, and enticed him to join her in a mausoleum which she had built in order that "they might die together." Antony committed suicide, in the mistaken belief that she had already done so. Octavian refused to yield to the charms of Cleopatra, who put an end to her life by applying an asp to her bosom, according to the common tradition, on Aug. 29, 30 B.C. With her ended the dynasty of the Ptolemies, and Egypt was made a Roman province. Cleopatra had three children by Antony, and by Julius Caesar, it is said, a son, Caesarion, who was put to death by Octavian.

For the history of Cleopatra *see* ANTONIUS; CAESAR, GAIUS JULIUS; PTOLEMIES. The life of Antony by Plutarch is our main authority; it is upon this that Shakespeare's *Antony and Cleopatra* is based. Her life is the subject of monographs by Stahr (1879, an *apologia*), and H. Houssaye, *Aspasie, Cléopâtre*, etc. (1879).

CLEOPATRA'S NEEDLES, the name popularly given to the two Egyptian obelisks presented to the British and American people respectively, and now standing on the Thames Embankment in London and in the Central Park of New York city. Originally set up by Thotmes or Tethmosis III. at Heliopolis about 1500 B.C., they were removed by Caesar Augustus to adorn the Caesareum at Alexandria about 14 B.C. and there remained until removed (in each case by private munificence) to their present positions in 1878 and 1880. Both are of rose-red Syene granite, covered with hieroglyphical inscriptions, and are estimated to weigh some 200 tons. (*See* OBELISK.)

CLEPSYDRA, the chronometer of the Greeks and Romans, which measured time by the flow of water (Gr. κλέπτειν, to steal, and ὕδωρ, water). In its simplest form it was an earthenware globe of known capacity, pierced at the bottom with several small holes, through which the water escaped. It was employed to set a limit to speeches in courts of justice, hence the phrases *aquam dare* (Pliny, *Ep.* 6. 2. 7), to give the advocate speaking time, and *aquam perdere* (Quint. 11. 3. 52), to waste time.

The clepsydra is said to have been known to the Egyptians. There was one in the Tower of the Winds at Athens; the turret on the south side of the tower is supposed to have contained the cistern which supplied the water. *See* classical dictionaries, *s.v.*

ICHITECTURE" (SPON); D'ESPOUY, "MONUMENTS ANTIQUES" (MASSIN ET CIE); SIR BANISTER FLETCHER, "HISTORY OF ARCHITECTURE ON THE COMP 1928) BATSFORD; ARCHITECTURAL BOOK PUB. CO.

EXAMPLES OF CLERESTORIES (SEE ARTICLE, CLERESTOREY ON NEXT PAGE)
A, B, exterior and interior, Peterborough cathedral, Romanesque clerestorey window at the top; C, Roman clerestorey, tepidarium, Baths of Titus; D, modern adaptation of Roman type, the Pennsylvania Station, New York; E, Egyptian clerestorey lighting, hypostyle hall, Karnak; F, G, exterior and interior, Winchester cathedral, showing larger Gothic clerestorey

CLERESTORY, CLERESTOREY or **CLEARSTORY,** in architecture, any wall of a room carried higher than the surrounding roofs so that windows can be pierced in it to light the room. In a large building, where interior walls are far from the outside of the building, some such method of lighting the central part becomes necessary, and the use of the clerestorey appears as early, at least, as the 18th dynasty in Egypt, under which the great hypostyle hall of the temple at Karnak was built. This had a central range of columns, higher than those on either side, to allow clerestoreys to be built of pierced stone slabs. In Roman architecture, many great halls were thus lighted, usually groined vaults over the central hall allowed of large semicircular windows being built above the side roofs; *e.g.*, S. Maria degli Angeli, at Rome (the tepidarium of the Baths of Diocletian) and the basilica of Constantine, at Rome. Similarly, the walls under the side arches of S. Sophia at Constantinople, are clerestorey walls. It was, however, in the Romanesque and Gothic churches of the middle ages, that the clerestorey idea received its most adequate expression. *See* p. 801 for illustrations of Clerestories. (*See* BYZANTINE AND ROMANESQUE ARCHITECTURE; GOTHIC ARCHITECTURE.)

CLERFAYT or **CLAIRFAYT, FRANÇOIS SEBASTIEN CHARLES JOSEPH DE CROIX,** COUNT OF (1733–1798), Austrian field marshal, entered the Austrian army in 1753. In the Seven Years' War he greatly distinguished himself, and in 1787 took part in the Turkish war. In 1792 he received the command of the Austrian contingent in the duke of Brunswick's army, and at Croix-sous-Bois his corps inflicted a reverse on the French. In the Netherlands he opened the campaign of 1793 with the victory of Aldenhoven and the relief of Maestricht, and on March 18 brought about the complete defeat of Dumouriez at Neerwinden. His victorious career was checked by the reverse at Wattignies, and in 1794 he was unsuccessful in West Flanders against Pichegru. Clerfayt succeeded the duke of Saxe-Coburg in the supreme command, but was quite unable to make head against the French, and had to recross the Rhine. In 1795, now field marshal, he commanded on the middle Rhine against Jourdan, whom he defeated at Höchst and Mainz. His action in concluding an armistice with the French not being approved by Thugut, he resigned the command, and became a member of the Aulic Council in Vienna. He died in 1798.

See von Vivenot, *Thugut, Clerfayt, und Würmser* (Vienna, 1869).

CLERGY, a collective term signifying strictly the body of "clerks," *i.e.*, men in holy orders (*see* CLERK); but extended in modern times so as to embrace all varieties of ordained Christian ministers, though in England the word "clergyman" is still mainly restricted to the clergy of the Established Church. In the Roman Catholic Church the word, which is the O.Fr. *clergie*, from Low Lat. *clericatus*, embraces the whole hierarchy of *clerici*, whether in holy or merely minor orders; it has also been loosely used to include the members of religious orders. The M.E. senses of "clerkship" and "learning" have long been obsolete.

In distinction to the "clergy" we find the "laity" (Gr. λαός, people), the great body of "faithful people" which, in nearly every conception of the Christian Church, stands in relation to the clergy as a flock of sheep to its pastor. This distinction was of early growth, and developed during the middle ages into lively opposition (*see* MONASTICISM; CHURCH HISTORY; PAPACY; INVESTITURE). The extreme claim of the great mediaeval popes, that the priest, as "ruler over spiritual things," was as much superior to temporal rulers as the soul is to the body (*see* INNOCENT III.) led logically to the vast privileges and immunities enjoyed by the clergy, which consisted mainly in exemption from public burdens, both as regarded person and pocket, and in immunity from lay jurisdiction. This last privilege extended to matters both civil and criminal; though, as Bingham shows, it did not (always and everywhere) prevail in cases of heinous crime (*Origines Eccles.* bk. v.).

This subjection of the clergy only to courts disposed by *esprit de corps* to judge leniently led to the penalties for criminous clerks being much lighter than those to which laymen were amenable; and this in turn led to the survival in England, long after the Reformation, of the legal fiction of benefit of clergy, used to mitigate the harshness of the criminal law.

CLERGY, BENEFIT OF, an obsolete but once very important feature in English criminal law. Benefit of clergy began with the claim on the part of the ecclesiastical authorities in the 12th century that every *clericus* should be exempt from the jurisdiction of the temporal courts and be subject to the spiritual courts alone. The issue of the conflict was that the common law courts abandoned the extreme punishment of death assigned to some offences when the person convicted was a *clericus*, and the church was obliged to accept the compromise and let a secondary punishment be inflicted. The term "clerk" or *clericus* always included a large number of persons in what were called minor orders, and in 1350 the privilege was extended to secular as well as to religious clerks; and, finally, the test of being a clerk was the ability to read the opening words of verse 1 of Psalm li., hence generally known as the "neck-verse." Even this requirement was abolished in 1705. In 1487 it was enacted that every layman, when convicted of a clergyable felony, should be branded on the thumb, and disabled from claiming the benefit a second time. The privilege was extended to peers, even if they could not read, in 1547, and to women, partially in 1622 and fully in 1692. The partial exemption claimed by the Church did not apply to the more atrocious crimes, and hence offences came to be divided into clergyable and unclergyable. According to the common practice in England of working out modern improvements, through antiquated forms, this exemption was made the means of modifying the severity of the criminal law. It became the practice to claim and be allowed the benefit of clergy; and when it was the intention by statute to make a crime really punishable with death, it was awarded "without benefit of clergy." The benefit of clergy was abolished by a statute of 1827, but as this statute did not repeal that of 1547, under which peers were given the privilege, a further statute was passed in 1841 putting peers on the same footing as commons and clergy.

For a full account of benefit of clergy *see* Pollock and Maitland, *History of English Law;* Stephen, *History of the Criminal Law of England;* E. Friedberg, *Corpus juris canonici* (*Leipzig,* 1879–81).

CLERGYMAN, an ordained minister of the Christian Church. In England the term is usually confined to the ministers of the established Church. Educational qualifications for this work vary with the different denominations, but the majority require at least two or three years of religious specialization beyond a four year college course, with a growing tendency towards higher standards in general to meet the challenges of modern thought and inquiry. Good health, intellectual ability, moral integrity, a desire to serve, breadth of knowledge and understanding, spiritual conviction, love of humanity and poise are some of the personal attributes necessary inasmuch as the clergyman serves variously as preacher, leader of worship, teacher, educator, pastor, social worker and executive.

CLERGY RESERVES, in Canada. By the act of 1791, establishing the provinces of Upper and Lower Canada, the British Government set apart one-eighth of all the crown lands for the support of "a Protestant clergy." These reservations, after being for many years a stumbling-block to the economic development of the province, and the cause of much bitter political and ecclesiastical controversy, were secularized by the Canadian parliament in 1854, and the proceeds applied to other purposes, chiefly educational. Owing to the wording of the imperial act, the amount set apart is often stated as one-seventh, and was sometimes claimed as such by the clergy.

CLERK, SIR DUGALD (1854–1932), Scottish civil engineer, was born at Glasgow on March 31, 1854. He was educated at the West of Scotland Technical college and the Andersonian college. He invented the Clerk cycle gas engine in 1877, improving it in 1878 (*see* INTERNAL COMBUSTION ENGINES), and became an authority on internal combustion engines. He also interested himself in motor engineering. During World War I he became director of engineering research to the Admiralty, and until 1919 was a member of the advisory committee for aeronautics to the Air Ministry, and also of the air inventions committee. In 1908 he was elected F.R.S., and in 1917 knighted. His works include *The Gas and Oil Engine* and many scientific papers.

CLERK, in its original sense, as used in the civil law, one who had taken religious orders of whatever rank, whether "holy" or "minor." In English ecclesiastical law, a clerk was any one who had been admitted to the ecclesiastical state, and had taken the tonsure. The application of the word in this sense gradually underwent a change, and "clerk" became more especially the term applied to those in minor orders, while those in "major" or "holy" orders were designated in full "clerks in holy orders." After the Reformation the word "clerk" was still further extended to include laymen who performed duties in cathedrals, churches, etc., *e.g.*, the choirmen, who were designated "lay clerks." Of these lay clerks or choirmen there was always one whose duty it was to be constantly present at every service, to sing or say the responses as the leader or representative of the laity. His duties were gradually enlarged to include the care of the church and precincts, assisting at baptisms, marriages, etc., and he thus became the precursor of the later *parish clerk*. In a somewhat similar sense we find *bible clerk, singing clerk*, etc. The use of the word "clerk" to denote a person ordained to the ministry is now mainly legal.

From the fact that in mediaeval times learning was chiefly the province of the clergy, they were engaged in nearly all occupations requiring knowledge of writing combined with some education and hence the word "clerk" came to its present indefinite signification of a writer in the employment of some one else. Older and more specific use of the word is to be traced in *clerk of the market, clerk of the petty bag, clerk of the peace, town clerk*, etc.

CLERKE, AGNES MARY (1842–1907), English astronomer and scientific writer, was born on Feb. 10, 1842, and died in London on Jan. 20, 1907. Her chief works were *A Popular History of Astronomy during the 19th Century* (1885, 4th ed. 1902); *The System of the Stars* (1890, 2nd. ed. 1905); and *Problems in Astrophysics* (1903). In 1903 she was elected an honorary member of the Royal Astronomical Society.

CLERKENWELL (klar'kĕn-wĕl), a district on the north side of the City of London, England, within the metropolitan borough of Finsbury (*q.v.*). It is so called from one of several wells or springs in this district, near which miracle plays were performed by the parish clerks of London. This well existed until the middle of the 19th century. Here was situated a priory, founded in 1100, which grew to great wealth and fame as the principal institution in England of the Knights Hospitallers of the Order of St. John of Jerusalem. Its gateway (1504), in St. John's Square, survived the suppression of the monasteries, and was the scene of Dr. Johnson's work in connection with the *Gentleman's Magazine*. In modern times the gatehouse again became associated with the Order, and is the headquarters of the St. John's Ambulance Association. An early English crypt remains beneath the neighbouring parish church of St. John, where the notorious deception of the "Cock Lane Ghost," in which Johnson took great interest, was exposed. Adjoining the priory was St. Mary's Benedictine nunnery, St. James's church (1792) marking the site. In the 17th century Clerkenwell became a fashionable place of residence. It has small watch-making and jeweller's industries, which have been long established here.

CLERMONT, a town of northern France, in the department of Oise, on the right bank of the Brèche, 41 mi. N. of Paris on the Northern railway to Amiens. The town was probably founded during the time of the Norman invasions and was a military post during the middle ages. It was several times taken and retaken during the Hundred Years' War, and the Wars of Religion. Population (1936) 5,943. The hill on which the town is built is surmounted by a keep of the 14th century, a relic of the once-famous fortress. The church dates from the 14th to the 16th centuries. The *hôtel-de-ville*, built by King Charles IV., who was born at Clermont in 1298, is the oldest in the north of France. The Promenade du Châtellier occupies the site of the old ramparts.

Clermont was at one time the seat of a countship, the lords of which were already powerful in the 11th century. Raoul de Clermont, constable of France, died at Acre in 1191, leaving a daughter who brought Clermont to her husband, Louis, count of Blois and Chartres. Theobald, count of Blois and Clermont, died in 1218 without issue, and King Philip Augustus, having received the countship of Clermont from the collateral heirs of this lord, gave it to his son Philip Hurepel, whose daughter Jeanne, and his widow, Mahaut, countess of Dammartin, next held the countship. It was united by St. Louis to the crown, and afterwards given by him (1269) to his son Robert, from whom sprang the house of Bourbon. In 1524 the countship of Clermont was confiscated from the constable de Bourbon, and later (1540) given to the duke of Orléans, to Catherine de' Medici (1562), to Eric, duke of Brunswick (1569), from whom it passed to his brother-in-law Charles of Lorraine (1596), and finally to Henry II., prince of Condé (1611). In 1641 it was again confiscated from Louis de Bourbon, count of Soissons, then in 1696 sold to Louis Thomas Amadeus of Savoy, count of Soissons, in 1702 to Françoise de Brancas, princesse d'Harcourt, and in 1719 to Louis-Henry, prince of Condé. From a branch of the old lords of Clermont were descended the lords of Nesle and Chantilly.

CLERMONT-FERRAND, a city of central France, capital of the department of Puy-de-Dôme, 113 m. W. of Lyons, on the P.L.M. railway. Pop. (1906) 44,113; (1936) 95,237. Clermont-Ferrand is situated on high ground on the western border of the fertile plain of Limagne. On the north, west and south it is surrounded by hills, with a background of mountains amongst which the Puy-de-Dôme stands out prominently. A small river, the Tiretaine, borders the town on the north. Since 1731 it has been composed of the two towns of Clermont and Montferrand.

Gergovia was the native centre in Auvergne but the Roman settlement known as Augustonemetum on the site of Clermont became so important as to be called later "The city of the Arverni." The present name is derived from Clarus Mons originally applied only to the citadel, but used for the town as early as the 9th century. During the disintegration of the Roman empire Clermont suffered from capture and pillage. Its history during the middle ages chiefly records the struggles between its bishops and the counts of Auvergne, and between the citizens and their overlord the bishop. It was the seat of seven ecclesiastical councils, held in the years 535, 549, 587, 1095, 1110, 1124 and 1130. In the council of 1095 Pope Urban II. proclaimed the first crusade. It figured in the wars against the English in the 14th and 15th centuries and in the religious wars of the 16th century. *Les Grands Jours de Clermont* (1665) was associated with the trial and execution of a member of the nobility who had tyrannized the district. Before the Revolution the town possessed the abbey of Saint Allyre, founded, it is said, in the 3rd century by St. Austremonius (St. Stremoine), the apostle of Auvergne and first bishop of Clermont, and the abbey of St. André, where the counts of Clermont were buried. The cathedral, a Gothic edifice, was begun in the 13th century. The stained glass dates from the 13th century. The church of Notre-Dame-du-Port is a typical example of the Romanesque style of Auvergne, dating chiefly from the 11th and 12th centuries. The exterior of the apse with its four radiating chapels, and its black and white decoration is the most interesting part. Among the old houses one, dating from the 16th century, was the birthplace of Blaise Pascal. Montferrand has several interesting houses of the 15th and 16th centuries, and a church of the 13th, 14th and 15th centuries. Clermont has several fine squares like the one erected by Bishop Jacques d'Amboise in 1515.

Clermont-Ferrand is the seat of a bishopric and a prefecture; it has tribunals of first instance and of commerce, a board of trade-arbitrators, and a chamber of commerce. It is a university town and has an important library, as well as the *Musée Lecoq* (natural history and geology) and the *Musée d'Art et d'Archéologie*. The town manufactures semolina and other farinaceous foods, confectionery, preserved fruit and jams, chemicals and heavy rubber goods, especially motor tires. Clothing is also important. Clermont is the chief market for the grain and other agricultural produce of Auvergne and Velay. Its waters are in local repute. On the bank of the Tiretaine there is a remarkable calcareous spring, the fountain of St. Allyre. About 1½ miles to the west lies the famous spa of Royat.

CLERMONT-GANNEAU, CHARLES SIMON (1846–1923); French Orientalist, the son of a sculptor of some repute,

was born in Paris, Feb. 19, 1846, and died Feb. 15, 1923. He laid the foundation of his reputation by his discovery (in 1870) of the "stele" of Mesha (Moabite Stone), which bears the oldest Semitic inscription known. In 1874 he was employed by the British Government to take charge of an archaeological expedition to Palestine, and was subsequently entrusted by his own government with similar missions to Syria and the Red sea. After serving as vice-consul at Jaffa from 1880 to 1882, he returned to Paris as "secrétaire-interprète" for oriental languages, and in 1886 was appointed consul of the first class. He subsequently accepted the post of director of the École des Langues Orientales and professor at the Collège de France. In 1889 he was elected a member of the Académie des Inscriptions et Belles Lettres, of which he had been a correspondent since 1880. In 1896 he was promoted to be consul-general, and was minister plenipotentiary in 1906. He was the first in England to expose the famous forgeries of Hebrew texts offered to the British Museum by M. W. Shapira in 1883, and in 1903 he took a prominent part in the investigation of the so-called "tiara of Saïtapharnes." This tiara had been purchased by the Louvre for 400,000 francs, and exhibited as a genuine antique, but was agreed to be of modern manufacture.

His chief publications, besides a number of contributions to journals, are:—*Palestine inconnue* (1886), *Études d'archéologie orientale* (1880, etc.), *Les Fraudes archéologiques* (1885), *Recueil d'archéologie orientale* (1885–1924), *Album d'antiquités orientales* (1897, etc.).

CLERMONT-L'HÉRAULT, a town of southern France in the department of Hérault, 10 mi. S.S.E. of Lodève. Pop. (1936) 5,098. The town is built on a hill crowned by an ancient castle and skirted by the Rhonel, a tributary of the Lergue. The church dates from the 13th and 14th centuries. Its woollen industry dates from the latter half of the 17th century. Tanning and leather-dressing are also carried on, and there is trade in wine. Among the public institutions are a tribunal of commerce, a chamber of arts and manufactures and a board of trade-arbitration. The town was several times taken and retaken in the religious wars of the 16th century.

CLERMONT-TONNERRE, STANISLAS MARIE ADELAIDE, Comte de (1757–1792), French politician, was born at Pont-à-Mousson on Oct. 10, 1757. Sent to the states-general in 1789 by the noblesse of Paris, he joined the Third Estate, and was elected president of the Constituent Assembly on Aug. 17, 1789. On the rejection by the Assembly of the scheme elaborated by the first constitutional committee, he attached himself to the party of moderate royalists, known as *monarchiens,* led by P. V. Malouet. His speech in favour of reserving to the crown the right of absolute veto under the new constitution drew down upon him the wrath of the advanced politicians of the Palais Royal; but he continued to advocate a moderate liberal policy, especially in the matter of removing the political disabilities of Jews and Protestants and of extending the system of trial by jury. In Jan. 1790 he collaborated with Malouet in founding the Club des Impartiaux and the *Journal des Impartiaux,* the names of which were changed in November to the Société des Amis de la Constitution Monarchique and *Journal de la Société,* etc., in order to emphasize their opposition to the Jacobins (Société des Amis de la Constitution). This club was denounced by Barnave in the Assembly (Jan. 21, 1791), and on March 28 it was attacked by a mob, whereupon it was closed by order of the Assembly. Clermont-Tonnerre was murdered by the populace during the rising of Aug. 9–10, 1792.

See *Recueil des opinions de Stanislas de Clermont-Tonnerre* (1791), the text of his speeches as published by himself; A. Aulard, *Les Orateurs de la Constituante* (1905).

CLERUCHY, a kind of colony of Athenian citizens planted in a conquered country. The settlers retained their status as citizens of Athens, and their allotments were politically part of Attic soil. These settlements were of three kinds: (1) where the inhabitants were extirpated and the settlers occupied the whole territory; (2) where the settlers occupied allotments in the midst of a conquered people; and (3) where the inhabitants gave up portions of land to settlers in return for certain pecuniary concessions. The primary object was unquestionably military, and in the later days of the Delian League (*q.v.*) the system was a precaution against disaffection on the part of the allies.

A secondary object of the cleruchies was to provide a source of livelihood to the poorer Athenians. Plutarch suggests that Pericles by this means rid the city of mischievous loafers; but it would appear that the cleruchs were selected by lot, and a wise policy would not entrust important military duties to wastrels. In 50 years about 10,000 cleruchs went out, so that the reduction of the citizen population was considerable.

The cleruchs were liable to military service and to that taxation which fell upon Athenians at home. They were not liable for the tribute paid by members of the Delian League; this follows from their status as Athenian citizens. In internal government the cleruchs adopted the Boulē and Assembly system of Athens itself; so we read of Polemarchs, Archons *eponumoi, Agoranomoi, Strategoi,* in various places. With local self-government there was combined a certain central authority in jurisdiction; the more important cases, particularly those between a cleruch and a citizen at home, were tried before the Athenian dicasts.

Bibliography.—*See* G. Gilbert, *Constitutional Antiquities of Athens and Sparta* (Eng. trans., 1895); A. H. J. Greenidge, *Handbook of Greek Constitutional Antiquities* (1896); L. Whibley, *Companion to Greek Studies* (1916); for the Periclean cleruchs, *see* Pericles; Delian League.

CLERVAUX (*clara vallis*), a town in the northern province of Oesling, grand-duchy of Luxembourg, on the Clerf, a tributary of the Sure. Pop. (1935) 1,671. The old castle of the Lannoy family still exists. In 1798 the people of Clervaux specially distinguished themselves against the French establishment of conscription.

The survivors of this Kloppel-krieg ("cudgel war") were shot, and a fine monument commemorates them.

CLETUS, or **ANENCLETUS,** the third pope, who occupied the papal chair *c.* 79–91. According to Epiphanius and Rufinus, he directed the Roman Church with Linus, successor to St. Peter, during Peter's lifetime.

CLÆVE (Clèves), a town of Germany in the Prussian Rhine province, formerly the capital of the duchy of its own name, 46 m. N.W. of Düsseldorf, 12 mi. E. of Nijmwegen, on the main Cologne-Amsterdam railway. Population 20,296.

The town was the seat of the counts of Cleve as early as the 11th century, but it did not receive municipal rights until 1242. The duchy of Cleve, which lay on both banks of the Rhine passed in 1368 to the counts of La Marck and was made a duchy in 1417, being united with the neighbouring duchies of Jülich and Berg in 1521. By the treaty of Xanten in 1614, Cleve passed to the elector of Brandenburg, being afterwards incorporated with the electorate by the elector, Frederick William. The part of the duchy on the left bank of the Rhine was ceded to France in 1795; the remaining portion in 1805. In 1815 it was restored to Prussia, except some small portions which were given to the kingdom of Holland. The town is built in the Dutch style, lying on three small hills in a fertile district near the frontier of Holland, about 2 m. from the Rhine, with which it is connected by a canal (the Spoykanal). The old castle of Schwanenburg is associated with the legend of the "Knights of the Swan," immortalized in Wagner's *Lohengrin.* The building has been restored in modern times to serve as a court of justice and a prison. The collegiate church (Stiftskirche) dates from about 1340. The Annexkirche, formerly a convent of the Minorites, dates from the middle of the 15th century. The chief manufactures are boots and shoes, tobacco and machinery; there is also some trade in cattle and in wine. There are mineral wells. It is a favourite summer resort.

CLEVEDON, watering place and urban district, Somersetshire, England, on the Bristol Channel, 15½ mi. W.S.W. of Bristol on a branch of the G.W.R. Pop. (1938) 7,754. Area 5 sq.mi. The cruciform church of St. Andrew has Norman and later portions. Clevedon Court is a mansion dating from the 14th century, though much altered in the Elizabethan and other periods. The town's popularity is due mainly to the fine scenery.

CLEVELAND, BARBARA VILLIERS, Duchess of (1641–1709), mistress of the English king, Charles II., was the daughter of William Villiers, 2nd Viscount Grandison (d. 1643) by

his wife Mary (d. 1684), daughter of Paul, 1st Viscount Bayning. In April 1659 Barbara married Roger Palmer, who was created earl of Castlemaine two years later, and soon after this marriage her intimacy with Charles II. began. The king was probably the father of her first child, Anne, born in Feb. 1661, although the paternity was also attributed to one of her earliest lovers, Philip Stanhope, 2nd earl of Chesterfield (1633–1713). Mistress Palmer was made a lady of the bedchamber to Catherine of Braganza. Her house became a rendezvous for the enemies of Clarendon, and according to Pepys she exhibited a wild paroxysm of delight when she heard of the minister's fall from power in 1667. Her influence, which had been gradually rising, became supreme at court in 1667 owing to the marriage of Frances Stuart (la belle Stuart) (1648–1702) with Charles Stuart, 3rd duke of Richmond (1640–72). Accordingly, Louis XIV., instructed his ambassador to pay special attention to Lady Castlemaine, who had become a Roman Catholic in 1663.

In Aug. 1670 she was created countess of Southampton and duchess of Cleveland, with remainder to her first and third sons, Charles and George Palmer, the king at this time not admitting the paternity of her second son Henry. About 1670 her influence over Charles began to decline. She consoled herself meanwhile with other lovers, among them John Churchill, afterwards duke of Marlborough and William Wycherley; by 1674 she had been entirely supplanted at court by Louise de Kérouaille, duchess of Portsmouth. The duchess of Cleveland then went to reside in Paris, where she formed an intrigue with the English ambassador, Ralph Montagu, afterwards duke of Montagu (d. 1709) who lost his position through some revelations which she made to the king. She returned to England just before Charles's death in 1685. In July 1705 her husband, the earl of Castlemaine, whom she had left in 1662, died; and in the same year the duchess was married to Robert (Beau) Feilding (d. 1712), a union which was declared void in 1707, as Feilding had a wife living. She died at Chiswick on Oct. 9, 1709.

Her eldest son, CHARLES FITZROY (1662–1730), was created in 1675 earl of Chichester and duke of Southampton, and became duke of Cleveland, and earl of Southampton on his mother's death. Her second son, Henry (1663–90), was created earl of Euston in 1672 and duke of Grafton in 1675; by his wife Isabella, daughter of Henry Bennet, earl of Arlington, he was the direct ancestor of the later dukes of Grafton; the most popular and the most able of the sons of Charles II., he met his death through a wound received at the storming of Cork. Her third son, George (1665–1716), was created duke of Northumberland in 1683 and died without issue. Her daughters were Anne (1661–1722), married in 1674 to Thomas Lennard, Lord Dacre (d. 1715), who was created earl of Sussex in 1684; Charlotte (1664–1718), married in 1677 to Edward Henry Lee, earl of Lichfield (d. 1716); and Barbara (1672–1737), the reputed daughter of John Churchill, who entered a nunnery in France, and became by James Douglas, afterwards 4th duke of Hamilton (1658–1712), the mother of an illegitimate son, Charles Hamilton (1691–1754).

See G. S. Steinman, *Memoir of Barbara duchess of Cleveland* (1871) and *Addenda* (1874).

CLEVELAND (or CLEIVELAND), JOHN (1613–58), English poet and satirist, was born at Loughborough, and educated at Hinckley school under the Puritan, Richard Vines. At the age of 14 he entered Christ's college, Cambridge, and in 1634 was elected to a fellowship at St. John's. He opposed the candidature of Oliver Cromwell as M.P. for Cambridge, and on the triumph of the Puritan party removed (1643) to Oxford. His gifts as a satirist were already known and he was warmly received by the King, whom he followed (1645) to Newark. In that year he was formally deprived of his Cambridge fellowship as a "malignant." He was judge-advocate in the garrison at Newark, and under the governor defended the town until in 1646 Charles I. ordered the surrender of the place to Leslie.

His indignation when the Scots surrendered the King to the Parliament is expressed in "The Rebel Scot." Cleveland wandered over the country depending on the alms of the Royalists for bread, and in 1655 spent three months in Norwich gaol. He was released early in 1656, and found his way eventually to Gray's Inn, where Aubrey says he and Samuel Butler had a "club" every night. There he died on April 29 1658.

Cleveland's poems were more highly esteemed than Milton's by his contemporaries, and his popularity is attested by the very numerous editions of his works. His poems are therefore of great value as an index to the taste of the 17th century. His verse is frequently obscure and full of the far-fetched conceits of the "metaphysical" poets; but the energy of his invective leaves no room for obscurity in such pieces as "Smectymnuus, or the Club Divines," "Rupertismus" and "The Rebel Scot." His poem "On the Memory of Mr. Edward King," is included in the collection of verse which contained Milton's "Lycidas."

For a bibliographical account of Cleveland's poems *see* J. M. Berdan, *The Poems of John Cleveland* (New York, 1903), in which there is a table of the contents of 23 editions, of which the chief are: *The Character of a London Diurnal, with Several Select Poems* (1647); *Poems. By John Cleavland. With additions, never before printed* (1659); *J. Cleaveland Revived* . . . (1659), in which the editor, E. Williamson, says he inserted poems by other authors, trusting to the critical faculty of the readers to distinguish Cleveland's work from the rest; *Clievelandi Vindiciae* . . . (1677), edited by two of Cleveland's former pupils, Bishop Lake and S. Drake, who profess to take out the spurious pieces; and a careless compilation, *The Works of John Cleveland* . . . (1687), containing poems taken from all these sources.

CLEVELAND, STEPHEN GROVER (1837–1908), President of the United States from 1885 to 1889, and again from 1893 to 1897, was born, the fifth in a family of nine children, in Caldwell, Essex county, N.J., on March 18, 1837. His father, Richard F. Cleveland, a Presbyterian clergyman, was a descendant of Moses Cleveland, who emigrated from England to Massachusetts in 1635. The family removed to Fayetteville, N.Y., and afterwards to Clinton, N.Y. It was intended that young Grover should be educated at Hamilton college, but this was prevented by his father's death in 1852. After working several years he set out for Cleveland, O., but stopped near Buffalo, N.Y., to work for his uncle. In 1855 he became a clerk in a Buffalo law office and in 1859 was admitted to the bar. When the Civil War began, the three Cleveland brothers drew lots to see which should remain at home to support their mother; the lot fell to Grover, and when he was drafted he hired a substitute.

In 1863 he was appointed assistant district attorney of Erie county, of which Buffalo is the chief city. This was his first public office, and it came to him, as, apparently, all later preferments, without any solicitation of his own. Two years later (1865) he was the Democratic candidate for district attorney, but was defeated. In 1869 Cleveland was nominated by the Democratic Party for the office of sheriff, and, despite the fact that Erie county was normally Republican, was elected. The years immediately succeeding his retirement from the office of sheriff in 1873 he devoted to the practice of law, coming to be recognized as one of the leaders of the western New York bar. In the autumn of 1881 he was nominated by the Democrats for mayor of Buffalo. The city government had been characterized by extravagance and maladministration, and a revolt of the independent voters at the polls overcame the usual Republican majority and Cleveland was elected. As mayor he attracted wide attention by his independence and businesslike methods, and under his direction the various departments of the city government were thoroughly reorganized. His ability received further recognition when in 1882 he was nominated, by the strategy of his campaign managers, as candidate for governor. The Republican Party in the State was at that time weakened by quarrels within its ranks, and this advantage was greatly increased by the Republicans' nomination for governor of Charles J. Folger (1818–84), then secretary of the Treasury, about whose nomination the cry of Federal interference was raised as a result of the methods employed in securing his nomination. All this, together with the popularity of Cleveland, brought about Cleveland's election by the unprecedented plurality of 192,854. As governor, Cleveland's course was marked by the stern qualities he had displayed in his other public positions. The demands of party leaders were made subordinate to public interest. He promoted the passage of a good civil service law. All bills passed by the

legislature were subjected to the governor's laborious scrutiny, and the veto power was used without fear or favour.

In 1884 the Democratic Party had been out of power in national affairs for 23 years. In this year, however, the generally disorganized state of the Republican Party, weakened by the defection of a large group of Independents, known as "Mugwumps," gave the Democrats an unusual opportunity. Upon a platform which called for radical reforms in the administrative departments, the civil service and the national finances, Cleveland was nominated for president, despite the opposition of the Tammany delegation. The nominee of the Republican Party, James G. Blaine (*q.v.*), of Maine, had received the nomination only after a contest in which violent personal animosities were aroused. The campaign that followed was one of the bitterest political contests in American history. Cleveland was accused of favouring the South because he had avoided war service and his private life was attacked; on the other side Blaine was associated with certain political scandals in Washington. The result was close, but Cleveland carried New York and was elected by an electoral majority of 219 to 182.

Cleveland's first term was uneventful, but was marked by firmness, justice and steady adherence on his part to the principles which he deemed salutary to the nation. He was especially concerned in promoting a non-partisan civil service. He stood firmly by the "Pendleton bill" (1883), designed to classify the subordinate places in the service, and to make entrance and promotion depend upon competitive examination of applicants. It applied only to clerkships, but the president was authorized to add others to the classified service from time to time. He added 11,757 during his first term.

President Cleveland made large use of the veto power upon bills passed by Congress, vetoing or "pocketing" during his first term 413 bills, more than two-thirds of which were private pension bills. The most important bill vetoed was the Dependent Pension bill, a measure opening the door, by the vagueness of its terms, to frauds upon the Treasury. Many of these bills were supported by Democrats, and Cleveland's opposition further alienated party leaders. In 1887 there was a large and growing surplus in the Treasury. About two-thirds of the public revenue was derived from duties on imports, in the adjustment of which the doctrine of protection to native industry had a large place. Cleveland attacked the system with great vigour in his annual message of 1887. He did not propose the adoption of free trade, but the Administration tariff measure, known as the Mills bill, passed the House, and although withdrawn owing to amendments in the Republican Senate, it alarmed and exasperated the protected classes, among whom were many Democrats.

In the following year (1888) the Democrats renominated Cleveland, and the Republicans nominated Benjamin Harrison, of Indiana. The campaign turned on the tariff issue, and Harrison was elected, receiving 233 electoral votes to 168 for Cleveland who, however, received a popular plurality of more than 100,000. Cleveland then resumed the practice of law in New York.

Congress had passed a law in 1878 requiring the Treasury department to purchase a certain amount of silver bullion each month and coin it into silver dollars to be full legal tender, and no date was fixed for this operation to cease, both parties being in favour of this policy. Cleveland had written a letter for publication before he became president, saying that a financial crisis of great severity must result if this coinage were continued and expressing the hope that Congress would speedily put an end to it. In 1890 Congress, controlled by the Republican Party, passed the McKinley bill, by which the revenues of the Government were reduced by more than $60,000,000 annually. At this same time expenditures were largely increased by liberal pension legislation, and the Government's purchase of silver bullion almost doubled by the provisions of the new Sherman Silver Purchase Act of 1890.

In 1892 Cleveland was nominated for president a third time in succession. President Harrison was nominated by the Republicans, who had lost strength due to the passage of the McKinley bill. Cleveland received 277 electoral votes and Harrison 145, and 22 were cast for James B. Weaver, of Iowa, the candidate of the "People's" party. Cleveland's second term embraced some notable events. The most important was the repeal of the silver legislation. Nearly $600,000,000 of "fiat money" had been thrust into the channels of commerce in addition to $346,000,000 of legal tender notes that had been issued during the Civil War. A reserve of $100,000,000 of gold had been accumulated for the protection of these notes. In April 1893 the reserve fell below this sum. President Cleveland called an extra session of Congress to repeal the silver law. The House promptly passed the repealing act. In the Senate there was a protracted struggle. The Democrats now had a majority of that body and they were more pro-silver than the Republicans. The president had undertaken to coerce his own party to do something against its will, and it was only by the aid of the Republican minority that the passage of the repealing bill was at last made possible (Oct. 30). The mischief, however, was not ended. The deficit in the Treasury made it inevitable that the gold reserve should be used to meet current expenses; holders of legal tender notes presented them for redemption; borrowing was resorted to by the Government; bonds were issued and sold to the amount of $162,000,000; the business world was in a state of constant agitation; commercial distress was widespread; wages were reduced in many employments, accompanied by labour troubles. The centre of disturbance was the Pullman strike at Chicago, whence the disorder extended to the Pacific coast, causing riot and bloodshed in many places. After waiting a reasonable time, as he conceived, for Gov. Altgeld of Illinois to act, Cleveland, on July 6, 1894, despite Gov. Altgeld's protest, directed the military forces of the United States to clear the way for trains carrying the mails. The rioters in and around Chicago were dispersed in a single day, and within a week the strike was broken.

Another important event was the action of the Government regarding the question of arbitration between Great Britain and Venezuela (*q.v.*). On Dec. 17, 1895, President Cleveland sent to Congress a special message calling attention to Great Britain's action in regard to the disputed boundary line between British Guiana and Venezuela, and declaring the necessity of action by the United States to prevent an infringement of the Monroe Doctrine. Congress at once appropriated funds for an American commission to investigate the matter. The diplomatic situation became very acute for the moment. Negotiations with Great Britain ensued, and before the American commission finished its work Great Britain had agreed (Nov. 1896) to arbitrate on terms which safeguarded the national dignity on both sides.

Cleveland's independence and party difficulties were shown during his second term in his action in regard to the tariff legislation of his party in Congress. A tariff bill introduced in the House by William Lyne Wilson, of West Virginia, was so amended in the Senate through the instrumentality of Senator Arthur Pue Gorman and a coterie of anti-Administration Democratic senators that, although unwilling to veto it, the president signified his dissatisfaction with its too high rates by allowing it to become a law without his signature. He carried the fight with this group of senators to the Senate by letters in which he denounced their lack of support. Cleveland's second administration began by vigorous action in regard to Hawaii; he at once withdrew from the Senate the annexation treaty which President Harrison had negotiated, and started an attempt to restore the dethroned queen, Liliuokalani, but was not successful, owing to Hawaiian opposition.

During his second term Cleveland added no less than 44,004 places in the civil service to the classified list, bringing the whole number up to 86,932. Toward the end of this term the president became very much out of accord with his party on the free-silver question, in consequence of which the endorsement of the administration was withheld by the Democratic national convention at Chicago in 1896. In the ensuing campaign the president and his cabinet, with the exception of Hoke Smith (b. 1855), secretary of the interior, who resigned, gave their support to Palmer and Buckner, the national, or "Sound Money" Democratic nominees.

Cleveland's second term expired on March 4, 1897, and he then retired into private life, universally respected and constantly consulted, in the university town of Princeton, N.J., where he died on June 24, 1908. He was a trustee of Princeton university and Stafford Little lecturer on public affairs. Chosen in 1905 as a member of a committee of three to act as trustees of the majority of the stock of the Equitable Life Assurance company, he promoted the reorganization and the mutualization of that company, and acted as rebate referee for it and for the Mutual and New York Life insurance companies. He published *Presidential Problems* (1904) and *Fishing and Hunting Sketches* (1906). He was married in 1886 to Frances Folsom (1864–1947).

BIBLIOGRAPHY.—R. M. McElroy's authorized biography of Cleveland, *Grover Cleveland, the Man and the Statesman* (1925), is a comprehensive work. W. O. Stoddard's *Grover Cleveland* (1888; "Lives of the Presidents" series) and J. L. Whittle's *Grover Cleveland* (1896; "Public Men of Today" series) are judicious volumes; and "Campaign Biographies" (1884) were written by W. Dorsheimer, F. E. Goodrich, P. King and D. Welch; *Grover Cleveland, a Study in Political Courage* (1922) is interesting but perhaps too favourable, while the study of Cleveland by H. L. Stoddard in *As I Knew Them* (1927) takes a somewhat opposite viewpoint. A large amount of magazine literature has been devoted to President Cleveland's career. G. F. Parker had a series of articles in the *Saturday Evening Post* on Aug. 28, 1920, April 7, 1923, June 9, 1923, Nov. 10, 1923, March 29, 1924, under the titles "Grover Cleveland's Career in Buffalo," "Grover Cleveland's First Administration as President," "Grover Cleveland's Second Administration as President," "Grover Cleveland's Life in Princeton" and "Grover Cleveland's One Business Venture." See articles by Woodrow Wilson (*Atlantic Monthly*, vol. lxxix: "Cleveland as President"); Carl Schurz (*McClure's Magazine*, vol. ix: "Second Administration of Grover Cleveland"); William Allen White (*McClure's*, vol. xviii: "Character Sketch of Cleveland"); Gamaliel Bradford (*Atlantic Monthly*, Nov. 1920: "Grover Cleveland"); Walter B. Stevens (*Missouri Historical Review*, Jan. 1927: "When Cleveland Came to St. Louis"); and Henry L. Nelson (*North American Review*, vol clxxxviii). Also Jesse L. Williams, *Mr. Cleveland: A Personal Impression* (1909); G. F. Parker, *Recollections of Grover Cleveland* (1909); C. H. Armitage, *Grover Cleveland as Buffalo Knew Him* (1927); G. C. Griffin, *Writings on American History* (1906–23).

CLEVELAND, a city and port of entry of the state of Ohio, U.S., county seat of Cuyahoga county, the seventh largest city in the United States. It is on Lake Erie, at the mouth of the Cuyahoga river about 260 mi. N.E. of Cincinnati, 357 mi. E. of Chicago and 623 mi. W. of New York. Pop. (1950) 905,636; (1940) 878,336, of whom 179,784 were foreign-born and 84,504 Negroes. Of the 179,784 foreign-born, 24,771, or 13.8%, were born in Poland; 21,066, or 11.8%, in Czechoslovakia; 20,944, or 11.7%, in Hungary; 15,427, or 8.6%, in Germany; 14,103, or 7.9%, in Yugoslavia; and 11,967, or 6.7%, in Russia.

The city commands pleasant views from its position on a plateau, which, at places on bluffs along the shore, has elevations of about 75 ft. above the lake level and rises gradually toward the southeast to 115 ft., and on the extreme eastern border to more than 200 ft. above the lake, or about 800 ft. above sea level; the surface has, however, been cut deeply by the Cuyahoga, which there pursues a meandering course through a valley about ½ mi. wide. The city's shore line is 14.2 mi. long. The city has a land area of 73.1 sq.mi., much the greater part of which is east of the river. The streets are of unusual width (varying from 60 ft. to 132 ft.) and paved chiefly with asphalt and brick. For its many well-shaded streets, Cleveland became known as the "Forest City." The municipality maintains an efficient forestry department. About ½ mi. from the lake and the same distance east of the river is the public square, or Monumental park, in the business centre of the city. Thence the principal thoroughfares radiate. The river valley is spanned by several viaducts, of which the most noteworthy are the Main street bridge with its complete system of approaches, the double-deck Detroit-Superior high level bridge and the Lorain-Carnegie bridge. Lower Euclid avenue (the old country road to Euclid, O., and Erie, Pa.) is the centre of retail trade. This avenue, east of 12th street, was once bordered with handsome houses and spacious and beautifully ornamented grounds, and was famous as one of the finest residential streets in the country. Few homes remain and most of the residential areas are in the outlying sections of the city, in the suburban villages and the adjacent cities of Lakewood, Cleveland Heights, Euclid, East Cleveland, Parma, Shaker Heights, Garfield Heights, Maple Heights, South Euclid, Fairview Park, Lyndhurst, North Olmsted, Bay, Berea, Brooklyn, Mayfield Heights and Wickliffe. The building of the Union Terminal station radically changed lower Superior avenue, once the retail commercial centre, for the south side from the public square westward was vacated for buildings subsidiary to the railroad enterprises.

In 1902 the city arranged for grouping its public buildings—in the so-called "group plan." The courthouse and the city hall, separated by a park or mall, are on the edge of the plateau overlooking Lake Erie. The mall is 540 ft. wide and extends south 1,500 ft. to the federal building and public library on Superior avenue. East on 6th street, which leads to the city hall, are the board of education building and the public auditorium with 11,635 seats, housing also a music hall and little theatre. On the lower level near the lake is the stadium seating 78,189. The city has, besides, numerous fine office buildings, including that of the Society for Savings (an institution in which each depositor is virtually a stockholder), the Williamson, the National City, the Guardian, the Union Trust, the Engineers Bank, the Federal Reserve Bank and Hanna buildings; the Union Terminal building, with its tower 720 ft. high, visible for many miles from the city; the Ohio Bell Telephone building, of the newer pyramidal type; the *Plain Dealer* newspaper building; the Cleveland Trust company's bank; the Museum of Art; Trinity cathedral (Episcopalian); the Church of the Covenant (Presbyterian); St. John's cathedral (Catholic), which was rebuilt in 1947–48; the Temple (Jewish); the Severance hall of the symphony orchestra; the Allen Memorial Medical library. In the public square is a soldiers' and sailors' monument consisting of a granite shaft rising from a memorial room to a height of 125 ft., and surmounted with a figure of Liberty; in the same park also, are a bronze statue of Moses Cleaveland, the founder of the city, and a bronze statue of Tom L. Johnson, a notable mayor. On a commanding site in Lake View cemetery is the James A. Garfield memorial (finished in 1890) in the form of a tower (165 ft. high), designed by George Keller and built mostly of Ohio sandstone; in the base is a chapel containing a statue of Garfield, and several panels on which are portrayed various scenes in his life; his remains are in the crypt below the statue. In Rockefeller park are 20 "cultural gardens," where there are busts or statues of national heroes, including the Goethe-Schiller statue.

The 32 parks and parklands contain 2,129 ac., not including the airport of 1,200 ac. A chain of parks connected by driveways follows the picturesque valley of Doan brook, on the east border of the city. At the mouth of the brook, and on the lake front, is the beautiful Gordon park of 119 ac., formerly the private estate of William J. Gordon, but given by him to the city in 1893; from this extends up the Doan valley the large Rockefeller park, which was given to the city in 1896 by John D. Rockefeller and others, and which extends to and adjoins Wade park (86 ac., given by J. H. Wade) in which is the Museum of Art. Monumental park is divided into four sections (containing about 1 ac. each) by Superior avenue and Ontario street. There is also, under county authority, a system of metropolitan parks or "reservations," lying in river valleys on the borders of the county, in a half circle within a few miles of the city limits, and nearly touching Lake Erie on the east and west.

Education.—Cleveland has an excellent public-school system. A general state law, enacted in 1904, placed the management of school affairs in the hands of an elective council of seven members, five chosen at large and two by districts. This board has power to appoint a school director and a superintendent of instruction. The superintendent appoints the teachers; the director, all other employees; appointments are subject to confirmation by the board, and all employees are subject to removal by the executive officials alone. The plan of education minimizes routine, replacing traditional programs by new curricula based upon a more scientific study of childhood and youth. Greater attention is also paid to the differing interests and capacities of groups of pupils. In 1950 there were 13 senior and 20 junior high schools, and 115 schools for grades one to six, in the city. The budget for 1950 was

$24,805,316. Besides the public-school system there are many parochial schools; the University school for boys, with an eight years' course; the Hathaway Brown and the Laurel school for girls; the Western Reserve university, with its medical school (opened in 1843), the Franklin Thomas Backus law school (1892), the dental department (1892), Adelbert college (until 1882 the Western Reserve college, founded in 1826 at Hudson, O.), Flora Stone Mather college (1888), school of library science (1904), the school of applied social sciences (1916), the Frances Payne Bolton school of nursing (1923), the graduate school (reorganized in 1926); the Case Institute of Technology, founded in 1880 as the Case School of Applied Science by Leonard Case (1820–80) and opened in 1881; Cleveland college, a downtown branch of the university, under a separate board of trustees; Fenn college which offers day and evening classes on the co-operative plan; Notre Dame college (for women); Ursuline college (for women); Baldwin Wallace college; Schauffler College of Religious and Social Work; the Cleveland School of Art; John Carroll university, formerly St. Ignatius college (conducted by the Fathers of the Society of Jesus; incorporated 1890), which has an excellent seismological observatory. In 1950–51 Western Reserve university had 11,267 students, Case institute 1,999, John Carroll university 2,184, Baldwin Wallace college 1,725 (1949–50) and Fenn college 4,290. Educational work is carried on by the Museum of Art, through classes, lectures and special exhibitions and by the Museum of Natural History, opened in 1922, and by the Health museum, opened in 1940. The musical development of the city has been stimulated by the creation of a symphony orchestra and the organization of a school of music. The public library contained 2,634,533 vol. in 1949, the Western Reserve university libraries 600,000, including the affiliated Case library (separately endowed, formerly a subscription library) and the Mather college library. The Cleveland Medical library contained 70,000, the library of the Western Reserve Historical society more than 250,000 and the Cleveland Law library, in the courthouse, 75,000 vol. Many of the larger suburbs, notably East Cleveland, Cleveland Heights, Shaker Heights and Lakewood, have fine library systems of their own. In addition, the Cuyahoga county library system circulates books wherever there is no other library service. In the field of drama, the Play House, which owns two buildings, housing three theatres, is a widely known civic project which attracts students from all over the nation.

The city has a highly developed system of charitable and corrective institutions. A farm of approximately 2,000 ac., the Cleveland Farm colony, 11 mi. from the city, takes the place of workhouses, and has many cottages in which live those of the city's poor who were formerly classed as paupers and were sent to poorhouses, and who now apply their labour to the farm and are relieved from the stigma that generally attaches to inmates of poorhouses. On the "farm" the city maintains an "infirmary village," a tuberculosis sanatorium, a detention hospital, a convalescent hospital and houses of correction. On a farm 22 mi. from the city is the boys' home (maintained in connection with the juvenile court) for "incorrigible" boys. The "cottage" plan has been adopted; each cottage is presided over by a man and wife whom the boys call father and mother. At an equal distance from the city but farther west is a girls' home, similarly administered. Among the most important hospitals are the University hospitals group consisting of Lakeside, MacDonald House (maternity), Babies and Childrens and Hanna House; Cleveland State hospital (for the mentally ill); City; Cleveland Clinic; Deaconess Evangelical; Doctors'; Fairview Park; Glenville; Grace; Huron Road; Lutheran; Mount Sinai; Polyclinic; St. Alexis; St. John's; St. Luke's; St. Vincent Charity; Womans; and two U.S. hospitals, Marine and Brecksville Veterans Administration. The Goodrich House (1897) and Alta House are among the most efficient social settlements in the country. Cleveland has also its orphan asylums, homes for the aged, homes for incurables and day nurseries, besides a home for sailors, homes for young working women and retreats for unfortunate girls. The many charitable organizations, Protestant and Catholic, are united in a welfare federation. There is also a federation of Jewish charities. Their support comes from endowment funds and from the Community fund, created in 1919. The money for this fund is collected in annual "drives." The principal newspapers of the city are the *Plain Dealer* (1841, independent), which in 1917 acquired the *Leader* (1847, Republican); the *Press* (1878, independent); and the *News* (1889, Republican). Bohemian, Hungarian and German dailies are published.

Municipal Enterprise.—Municipal ownership was a prominent issue in Cleveland during the mayoralty of Tom Loftin Johnson (1854–1911), a street-railway owner, iron manufacturer, an ardent single-taxer, who was elected in 1901, and re-elected in 1903, 1905 and 1907. In transportation Johnson adopted the principle of service at cost, with the slogan "three-cent fare." The separate railways, with franchises expiring at different dates, had been consolidated into the Cleveland Electric Street Railway corporation. Since it was overcapitalized ($23,000,000), its managers considered the Johnson schemes visionary. His method of compulsion was through the council's right to grant or refuse franchises, or by organizing rival companies, which should lease their lines to a municipal traction company acting on behalf of the public. The war began by the organization of the Forest City Railway company in Nov. 1906. By 1908 the railway corporation was forced to lease its property to the municipal holding company. But Johnson's power began to wane and in 1909 he was defeated for re-election. The railway system was put in the hands of receivers. The receivership was administered under Federal Judge Robert W. Tayler, and the result in 1910 was a franchise for 25 years to the (renamed) Cleveland Railway company, embodying the "Tayler" plan, which also called for service at cost and a fare of three cents. With rising costs, especially after the outbreak of World War I, the fare had to be raised, partly because holders of the stock (radically deflated) were entitled to 6% dividends. With the depression which began in 1920, difficulties multiplied. In 1935 the franchise was not renewed, but the company had a right to a period of liquidation. In April 1942 the city acquired ownership and the system became known as the Cleveland Transit system. It was operated successfully thereafter under a transit board which spent millions of dollars to modernize the system and which in 1949–50 negotiated a loan from the Reconstruction Finance corporation for construction of a rapid transit system and further modernization. The municipality also owns a large electric power plant, an extensive water-pumping and -purification system (the water is taken from Lake Erie, 4½ mi. from shore) and garbage-reduction and sewage-disposal plants. The municipal airport (1,200 ac.) on the southwest edge of the city is one of the largest in the country. A smaller municipal airport on the lake front in the downtown area takes care of private planes.

Commerce and Transportation.—To meet the demands of the rapidly increasing commerce the harbour has been steadily improved. The outer harbour was formed by two breakwaters enclosing an area of 5 mi. long and 1,600 to 2,400 ft. wide; the main entrance, 700 ft. wide, lying opposite the mouth of the Cuyahoga river; the depth of the harbour ranges from 21 to 25 ft. The inner harbour comprises the Cuyahoga, the old river bed and connecting slips. The channel at the mouth of the river (325 ft. wide) is lined on the west side by a concrete jetty, 1,440 ft. long, and on the east side by commercial docks, 1,602 ft. long. The river and the old river bed furnish about 13 mi. of safe dock frontage, the channel having been dredged for 6 mi. to a depth of 21 ft. This work was extended by federal money.

Cleveland's rapid growth, both as a commercial and as a manufacturing city, is largely the result of its situation between the iron regions of Lake Superior and the coal and oil regions of Pennsylvania and Ohio. Cleveland is a great railway centre and is one of the most important ports on the Great Lakes. The city is served by the New York Central, the New York, Chicago and St. Louis, the Pennsylvania, the Erie, the Baltimore and Ohio and the Wheeling and Lake Erie railways and by steamboats to the principal ports on the Great Lakes. A number of domestic and international air lines also serve the city.

Cleveland is the largest ore market in the world, and its huge ore docks are among its most interesting features; the annual receipts and shipments of coal and iron ore are enormous. The most

important manufactures of the metropolitan area are iron and steel, automobile parts, machinery, chemicals and paints, printed products, petroleum products, fabricated metal products and clothing. More steel wire, wire nails and bolts and nuts are made there than in any other city in the world. The United States census of manufactures of 1947 showed the value added by manufacture to the following products in the Cleveland area to be: primary metal industries $219,272,000; fabricated metal products $184,485,000; chinery (except electrical) $138,126,000; chemical products, including paints, $123,162,000; transportation equipment $95,-102,000; printing and publishing $74,210,000; food processing $51,812,000; clothing $56,602,000; electrical machinery $51,-523,000. The total value added by manufacture in all Cleveland area industries in 1947 was $1,546,117,000. The value added by manufacture in Cuyahoga county alone exceeded that in any one of 34 entire states. Two suburban areas, one east in Euclid and the other in a group of southwestern suburbs, have had a rapid industrial growth beginning about 1940 as dozens of large factories arose there.

Government.—Since Cleveland became a city in 1836 it has undergone several important changes in government. The charter of that year placed the balance of power in a council composed of three members chosen from each ward and as many aldermen as there were wards, elected on a general ticket. From 1852 to 1891 the city was governed under general laws of the state which entrusted the more important powers to several administrative boards. Then, from 1891 to 1903, by what was practically a new charter, that which is known as the federal plan of government was tried; this centred power in the mayor by making him almost the only elective officer, by giving to him the appointment of his cabinet of directors—one for the head of each of the six municipal departments—and to each director the appointment of his subordinates. The federal plan was abandoned in 1903, a new municipal code coming into effect, which was in operation until 1909, when the Paine law established a board of control under a government resembling the old federal plan. In accordance with the authority conferred by the home-rule amendment of the state constitution, a charter, submitted by a special commission, was accepted by the citizens on July 1, 1913. This reduced the number of elected officers to the mayor and 25 councillors. By an amended charter, which took effect on Jan. 1, 1924, a manager system was introduced. This system was itself repealed in Nov. 1931 despite the advice of civic organizations. Under the amendment, a mayor and 33 councillors, one from each of the city's wards, are elected every odd year. The entire governmental setup was re-organized at the same time with the establishment of three administrative departments—law, finance and utilities—and several special commissions, with the mayor the dominant figure. The city has profited greatly from the interest in municipal problems which has been shown by organizations of leading citizens. Especially has this been manifested by the Cleveland Chamber of Commerce and the Citizens' league, an organization of influential professional and businessmen, which, by issuing bulletins concerning candidates at the primaries and at election time, has done much for the betterment of local politics. The Cleveland Chamber of Commerce, an organization of more than 4,200 business leaders, is a power for good in the city; besides its constant and aggressive work in promoting the commercial interests of the city, it was largely influential in the federal reform of the consular service; it studied the question of overcrowded tenements and secured the passage of a new tenement law with important sanitary provisions and fixed minimum air space; it urges and promotes home gardening, public baths, playgrounds, lunchrooms, etc., for employees in factories; and it was largely instrumental in devising and carrying out the so-called "group plan" creating the lake-front area.

History.—A trading post was established at the mouth of the Cuyahoga river as early as 1786, but the place was not permanently settled until 1796, when it was laid out as a town by Moses Cleaveland (1754–1806), who was then acting as the agent of the Connecticut Land company, which in the year before had purchased from the state of Connecticut a large portion of the Western Reserve. In 1800 the entire Western Reserve was erected into the county of Trumbull and a township government was given to Cleveland; ten years later Cleveland was made the seat of government of the new county of Cuyahoga, and in 1814 it was incorporated as a village. Cleveland's growth was, however, very slow until the opening of the Ohio canal as far as Akron, in 1827; about the same time the improvement of the harbour was begun, and by 1832 the canal was opened to the Ohio river. Cleveland was thus connected with the interior of the state, for whose mineral and agricultural products it became the lake outlet. The discovery of iron ore in the Lake Superior region made Cleveland the natural meeting point of the iron ore and the coal from the Ohio, Pennsylvania and West Virginia mines; and the city's great commercial importance dates from this time. The building of railways during the decade 1850–60 increased this importance, and the city grew with great rapidity. The growth during the Civil War was partly caused by the rapid development of the manufacturing interests of the city, which supplied large quantities of iron products and clothing to the federal government. The population of 1,076 in 1830 increased to 6,071 in 1840, 17,034 in 1850, 43,417 in 1860, 92,829 in 1870 and 160,146 in 1880. Until 1853 the city was confined to the east side of the river, but in that year Ohio City (which was founded in 1807, later incorporated as the village of Brooklyn, and in 1836 chartered as a city under the name Ohio City) was annexed. Other annexations followed: East Cleveland (a district east of the present 55th street, and not the suburban city of that name) in 1872, Newburg in 1873, West Cleveland and Brooklyn in 1893, Glenville and South Brooklyn in 1905, Collinwood in 1910 and West Park in 1923.

The most notable later events not mentioned elsewhere were the centennial celebration of 1896, the sesquicentennial observance of 1946, the establishment of a successful community fund, the successful Great Lakes exposition of 1936 and 1937 and the National Air races held at Cleveland airport.

CLEVELAND, a city of southern Tennessee, U.S., 29 mi. E.N.E. of Chattanooga, on federal highway 11 and the Southern railway; the county seat of Bradley county. The population in 1950 was 12,445; in 1940, 11,351; and in 1930, 9,136 by the federal census. There are manganese mines near by, and the city has more than 70 factories, employing 5,500 persons and producing goods valued at $15,000,000 annually. During the Civil War U. S. Grant and William T. Sherman for a time had headquarters there, in houses that are still standing. The battle of Ft. Hill was fought on the site of what is now Ft. Hill cemetery. Cleveland was settled about 1832 and was incorporated as a city in 1837. It was named after Col. Benjamin Cleveland, a commander at the battle of King's Mountain.

CLEVELAND HEIGHTS, a city of Cuyahoga county, Ohio, U.S., adjoining Cleveland on the east. It is a residential suburb, with a population of 58,782 in 1950; 54,992 in 1940 and 50,945 in 1930 by the federal census. It has a commission-manager form of government.

The village was incorporated in 1903 and in 1922 it became a city.

CLEVER, an adjective implying dexterous activity of mind or body, and ability to meet emergencies with readiness and adroitness. The etymology and the early history of the word are obscure. Some derive it, in the sense of "quick to seize," from M.E. *cliver* or *clivre*, a claw. This original sense probably survives in the frequent use of the word for nimble, dexterous, quick and skilful in the use of the hands, and so it is often applied to a

horse, "clever at his fences." The word has also been connected with O.E. *gléaw*, wise, which became in M.E. *gleu*, and is cognate with Scottish *gleg*, quick of eye.

CLEYNAERTS (CLENARDUS or CLÉNARD), **NICOLAS** (1495–1542), Belgian grammarian and traveller, was born at Diest, Brabant, on Dec. 5, 1495. Educated at the University of Louvain, he became a professor of Latin, which he taught by a conversational method. His *Institutiones in linguam graecam* (1530), and *Meditationes graecanicae* (1531) passed through a number of editions, and had many commentators. He maintained that the learner should not be puzzled by elaborate rules until he has obtained a working acquaintance with the language. In pursuit of a scheme for proselytism among the Arabs he travelled in 1532 to Spain, and tried in vain to gain access to the Arabic mss. in the possession of the Inquisition. Finally, in 1540, he set out for Africa to seek information for himself. He reached Fez, then a flourishing seat of Arab learning, but after 15 months of privation and suffering was obliged to return to Granada, and died in the autumn of 1542. He was buried in the Alhambra palace.

See his Latin letters to his friends in Belgium, *Nicolai Clenardi, Peregrinationum ac de rebus machometicis epistolae elegantissimae* (Louvain, 1550), and a more complete edition, *Nic. Clenardi Epistolarum libri duo* (Antwerp, 1561); also Victor Chauvin and Alphonse Roersch, "Étude sur la vie et les travaux de Nicolas Clénard" in *Mémoires couronnés* (vol. lx., 1900–01) of the Royal Academy of Belgium, which contains an extensive bibliography.

CLICHÉ. In the process of stereotype printing a matrix or mould is made in papier-mâché from the set type, and a solid casting is produced from this mould, which thus bears a surface of letters cast in relief, from which the actual prints are taken. The papier-mâché mould is called a cliché.

This term, representing as it does a mould for mechanical reproduction, has passed into use as an effective name for any hackneyed term or phrase. The cliché is the vice of the writer who trades in second-hand thought and expression; for him the sea becomes "the rolling wave," fire "the devouring element," and the sun "the orb of day."

CLICHTOVE, JOSSE VAN (d. 1543), Belgian theologian, educated at Louvain and Paris, became librarian of the Sorbonne. In 1519 he was elected bishop of Tournai, and in 1521 was translated to the see of Chartres. He is known as an antagonist of Luther. When Cardinal Duprat convened his Synod of Paris in 1528 to discuss the new religion, Clichtove was charged to collect and summarize the objections to the Lutheran doctrine. This he did in his *Compendium veritatum . . . contra erroneas Lutheranorum assertiones* (Paris, 1529). He died at Chartres on Sept. 22, 1543.

CLICHY, a manufacturing suburb of Paris. Pop. (1936) 56,475. It was, under the name of *Clippiacum*, a residence of the Merovingian kings. The church dates from the 17th century. The industries include the manufacture of starch, rubber, oil and grease, glass, chemicals and soap.

CLICKS, peculiar sounds of unknown origin, found in many languages. The German term *Schnalze* and the Afrikaans *klukken* are both attempts to give a descriptive name, but the English word *Click* is as onomatopoeic as any. The outstanding examples of click-speech are the Hottentot languages (Nama, !kora, Griqua, etc.) with four or five different clicks and those of the Bushmen of South Africa (!kung, kham, !ai, etc.), with as many as nine different clicks. From contiguity with the Hottentots and Bushmen several Bantu stocks have acquired clicks, which are alien to Bantu speech-systems. Such stocks are the Zulus and Kaffirs while the Damaras, (originally Bantu), have dropped their language entirely and speak only Hottentot. In the interior, Afrikaans (Cape Dutch), has even acquired clicks.

It seems fairly well established now, that clicks are by no means confined to these South African tongues. There are cases of their presence in the Melanesian languages of the Eastern Pacific, the Q of Codrington and Paterson representing a click-sound. Clicks never appear very far north of the equator and a definite "click-zone" can be found girdling the earth with, and south of, the equator. A recent study of the Quichua language of the Incas of Peru shows the existence of click-sounds, later rubbed down to simple gutturals, in the ancient tongue. The Aztec or Nahuatl tongue also had clicks and in the surviving Aztec spoken by Mexicans in the hills of the interior, the *tl*, final and initial, sounds exactly like a Hottentot dental click.

In the Nama speech (Standard Hottentot), there are four clicks, represented thus:

	Tindall	German system	International Phonetic Association
Dental . .	c	/	ǀ
Cerebral . .	q	!	ǃ
Palatal . .	v	ǂ	ǂ
Lateral . .	x	//	ǁ

In the Bushman languages (so far as classified, 16 in number) other clicks exist having such signs as:

Guttural ʃ Semi-labial ʗ Labial ʘ

The sounds must be heard; no description can do more than convey a general idea of their nature. The dental click, for example, is pronounced by pressing the flattened tip of the tongue against the front teeth at the gums and quickly withdrawing it. Early attempts to define and describe these sounds will be found in the works mentioned below.

See H. Tindall, *A Grammar of the Namaqua-Hottentot Language* (Cape Town, n.d.); J. L. Döhne, *Zulu-Kafir Dictionary* (Cape Town, 1857); Meinhof, *Lehrbuch der Namasprache* (1909); Leonhard, *Aus Namaland und Kalahari* (1905); N. Whymant, *The Zone of Clicks* (Tokyo, 1923). *See* also BUSHMAN LANGUAGES and HOTTENTOTS.

CLIFF-DWELLERS. Once believed to be a mysterious vanished race, the inhabitants of the cliff-dwellings in the south-western United States are now recognized as but Pueblo Indians of the prehistoric period characterized by black-on-white pottery; who, when under hostile pressure, lodged their homes and granaries on ledges under overhanging cliffs, where such were available; in other cases excavated horizontally into bluff faces, or built on steep-walled mesas. Their skeletal remains, artifacts, and masonry are identical with those of the same period found in ruins in canyon bottoms and valleys. The romantically inaccessible situation of the cliff ruins, however, is impressive. Among the best known are Cliff Palace and Spruce Tree House in Mesa Verde National Park, Colorado, and a series in Canyon de Chelly, Arizona.

See Nordenskiöld, *Cliff Dwellings of the Mesa Verde* (1893).

CLIFF-DWELLINGS, the general archaeological term for the habitations of certain primitive peoples, formed by utilizing natural recesses or shallow caverns in the faces of cliffs, sometimes with more or less modification to adapt them to the requirements of the buildings. They are to be distinguished from cave-dwellings, which, not necessarily high in cliff walls, usually were or are occupied in their natural state; and from rock-shelters, used for temporary shelter, for storage, as lookouts, and sometimes for sacrificial deposits and for burial of the dead. Dry caves have been used as habitations in all parts of the world, some of those in France and Spain dating from the earliest periods of human history. Caves are still inhabited in Tunis and in Central Africa, and as winter habitations by the Tarahumare and other Piman tribes of northern Mexico, who have modified the natural recesses by the addition of masonry windbreaks, storage-bins, etc. A class of cave-dwellers known as Basket-makers, of a culture older than that of the cliff-dwellers, lived in Utah, Colorado, Arizona and New Mexico; and another culture, known as Bluff-dwellers, occupied caves in the Ozark mountains of western Missouri-Arkansas. Other caves, such as Mammoth and Salts caves in Kentucky and Lovelock cave in Nevada, have yielded important artifacts of their primitive occupants.

Eskimo of King island in Bering strait, Alaska, as late at least as 1881, occupied winter houses made by excavating the loose granite rocks to form niches in a steep slope and by walling up the front and sides with stones placed over a driftwood framework, access being had by a long covered passage leading to an

CLIFF-DWELLINGS OF THE SOUTH-WESTERN UNITED STATES

1. Spruce Tree House, Mesa Verde National park, south-western Colorado, one of the largest Mesa Verde structures (216 feet long and 89 feet wide, containing 114 rooms and 8 kivas or assembly rooms). It is three storeys high in its loftiest part, and its chambers are round, rectangular or triangular to adapt themselves to the limited ground space which the dwelling occupies
2. The westerly edge of the Betátakin ruins, in the Navaho National Monument, in Arizona. These ancient stone houses are built more than a hundred feet above the canyon floor. Cliff-dwellings of this type extend over a wide area from southern Colorado as far south as the central part of Mexico
3. Cliff Palace, Mesa Verde National park. Among the Mesa Verde ruins have been found pottery remains; yucca sandals; woven cotton cloth; indications of reservoirs for irrigating; stone and bone implements; graves containing flexed skeletons; mummies; evidences of turkey domestication; and other mementos of the lives of the cliff-dwellers
4. Montezuma Castle, in Arizona. This cliff-dwelling, although distant from Mesa Verde, is similar to it, even in small details of construction
5. Cavate lodges of Puye, New Mexico, a type of cliff-dwelling consisting of communicating rooms excavated in the soft volcanic tuff of the cliffside, with terraced, flat-roofed houses built in front. These occur also along the Rio Verde in Arizona

opening in the floor. Ancient cliff-dwellings are found in the States of Chihuahua and Jalisco, Mexico, and especially in Colorado, Utah, Arizona and New Mexico, those in the Mesa Verde National park in southwestern Colorado being noted for the excellence of their architecture. It was once believed that the cliff-dwellers of southwestern United States were of a pre-Indian pygmy race, but archaeological study has shown the structures and the objects found in them to be unquestionably of Pueblo origin, contemporaneous with numerous mesa-top and valley ruins, the selection of their sites, made accessible only by hand-and-toe holes pecked in the cliff, having been due to hostile pressure. In the Mesa Verde canyons the largest and most noted cliff-dwellings are: Cliff Palace, consisting of about 150 secular rooms and 23 kivas or ceremonial chambers, together with various square and circular towers, all built in a very compact group and following the curving face of the recess for about 300 feet. Spruce-tree house, 216 ft. long and 89 ft. wide (114 rooms and 8 kivas), was three storeys high in its loftiest part; its chambers were built round, rectangular, or triangular according to the exigencies of the limited ground space. Balcony house (25 rooms) is named from a wide shelf extending along the front of two of the houses and is built on the projecting floorbeams. There are many other similar dwellings in the Mesa Verde canyons, some of which have been excavated; and on the summit of the mesa are massive related pueblo-like structures, used perhaps chiefly for ceremonial purposes, as well as many pit-houses. Other important cliff-dwellings of Arizona are Casa Blanca in Canyon de Chelly, Montezuma castle on Beaver creek of Verde river, and various examples (*e.g.*, Betátakin, Kitsil), in the Navaho National monument. Cliff-dwellings of this class extend from southern Colorado to central Mexico. Another type, known as cavate lodges, consists of groups of a few communicating rooms excavated in the friable volcano tuff of the cliffs, in front of which terraced houses of masonry with flat roofs were built. This class is common to the Puye and Rito de los Frijoles areas in northern New Mexico, and occurs also on the Rio Verde in Arizona.

CLIFFORD, the name of a famous English family and barony, taken from the village of Clifford in Herefordshire.

ROBERT DE CLIFFORD (1274–1314), one of the most powerful barons of his age, won great renown at the siege of Carlaverock castle in 1300, and after taking part in the movement against Edward II's favourite, Piers Gaveston, was killed at Bannockburn. His son ROGER, 2nd baron (1300–1322), shared in the rebellion of Thomas, earl of Lancaster, and was probably executed at York on March 23, 1322. JOHN, the 9th baron (1435–1461) earned the name of the "butcher," in the Wars of the Roses, in which he fought for Henry VI; after the battle of Wakefield in 1460 he murdered Edmund, earl of Rutland, son of Richard, duke of York. Shakespeare refers to this incident in King Henry VI, and also represents Clifford as taking part in the murder of York, though it is practically certain that York was slain in the battle. Clifford was killed at Ferrybridge on March 28, 1461, and was afterward attainted. His young son HENRY, the 10th baron (*c.* 1454–1523), lived disguised as a shepherd for some years; hence he is sometimes called the "shepherd lord." On the accession of Henry VII the attainder was reversed and he received his father's estate. He fought at Flodden in 1513, and died on April 23, 1523. He is the subject of two of Wordsworth's poems, "The White Doe of Rylstone" and the "Song at the Feast of Brougham Castle." HENRY, the 11th baron, was created earl of Cumberland (*q.v.*) in 1525, and from this time until the extinction of the title in 1643 the main line of Cliffords was associated with this earldom.

On the death of George, 3rd earl of Cumberland, in 1605, the barony of Clifford, separated from the earldom, was claimed by his daughter Anne, later countess of Dorset, Pembroke and Montgomery; and in 1628 a new barony of Clifford was created in favour of Henry, afterwards 5th and last earl of Cumberland. After Anne's death in 1676 the claim to the older barony passed to her daughter Margaret (d. 1676), wife of John Tufton, 2nd earl of Thanet, and her descendants, whose title was definitely recognized in 1691. After the Tuftons the barony was held with intervening abeyances by the Southwells and the Russells, and to this latter family the present Lord De Clifford belongs.

When the last earl of Cumberland died in 1643 the newer barony of Clifford passed to his daughter Elizabeth, wife of Richard Boyle, 2nd earl of Cork, and from the Boyles it passed to the Cavendishes, falling into abeyance in 1858.

The barony of Clifford of Lanesborough was held by the Boyles from 1644 to 1753, and the Devonshire branch of the family still holds the barony of Clifford of Chudleigh, created in 1672.

See G. E. C.(okayne), *Complete Peerage*, vol. iii, new ed. (London, 1913); and T. D. Whitaker, *The History and Antiquities of the Deanery of Craven*, 3rd ed. (Leeds, London, 1878).

CLIFFORD OF CHUDLEIGH, THOMAS CLIFFORD, 1ST BARON (1630–1673), English lord treasurer, the son of Hugh Clifford of Ugbrooke, near Exeter, was born on Aug. 1, 1630, matriculated at Exeter college, Oxford, in 1647, and entered the Middle Temple in 1648. He represented Totnes in the convention parliament of 1660 and in the parliament of 1661, and became a steady supporter of the earl of Arlington, in opposition to the chancellor, earl of Clarendon. On the outbreak of the Dutch war in 1664 Clifford was appointed commissioner for the care of the sick and of prisoners; afterward knighted and appointed ambassador to Denmark and Sweden, he served with the fleet in 1665 and 1666, and in Oct. 1667 was one of those selected by the commons to prepare papers concerning the naval operations. In 1666 he was made controller of the household and a privy councillor, in 1667 a commissioner for the treasury and in 1668 treasurer of the household.

As one of the Cabal ministry, Clifford co-operated zealously with the king in breaking through the Triple Alliance with Holland and Sweden and in effecting an understanding with France. He was the only minister, besides Arlington, entrusted with the secret treaty of Dover of 1670, which he signed as well as the ostensible treaty shown to all the members of the Cabal. In 1672, during the absence of Arlington and Coventry abroad, Clifford acted as principal secretary of state. He was chiefly responsible for the "stop of the exchequer" (which, through the suspension of all payments for 12 months, gave Charles the use of all revenue) and probably also for the attack upon the Dutch Smyrna fleet. He was appointed that year a commissioner to inquire into the settlement of Ireland. On April 22 he was raised to the peerage, and on Nov. 28, by the duke of York's interest, was made lord treasurer. This excited the jealousy of Arlington, who had always aspired to that office. It was, however, the Test Act of 1673 that brought about Clifford's downfall. On the passing of the bill Clifford followed the duke of York into retirement. He had, it would seem, been gradually moving towards Roman Catholicism and probably the Test act precipitated his conversion to the Roman faith. His resignation caused astonishment, since he had never publicly professed his religion, and in 1671 had even built a new Protestant chapel at his home at Ugbrooke. According to John Evelyn, however, his conduct was governed by a promise previously given to James. He gave up the treasurership and his seat in the privy council in June. On July 3, 1673, he received a general pardon

from the king as a safeguard against a possible impeachment by the commons. In August he said a last farewell to Evelyn, and in less than a month he died at Ugbrooke. In Evelyn's opinion the cause of death was suicide, but this seems very unlikely. The evidence is not strong nor was such an action in keeping with his character. Clifford was one of the worst advisers of Charles II, but sincere and consistent. Evelyn declares him "a valiant, uncorrupt gentleman; ambitious, not covetous; generous, passionate, a most constant, sincere friend." He married Elizabeth, daughter of William Martin of Lindridge, Devonshire (by whom he had 15 children, 3 sons and 6 daughters surviving him). He was succeeded by Hugh, his 5th but eldest surviving son.

See C. H. Hartmann, *Clifford of the Cabal* (London, Toronto, 1937).

CLIFFORD, SIR HUGH, G.C.M.G.; G.B.E. (1866–1941), British colonial governor, son of Maj.-Gen. Sir H. H. Clifford, V.C., K.C.M.G., was born in London on March 5, 1866, and was educated at Woburn Park. In 1883 Clifford passed into the Malay States civil service, and, after executing a special mission towards the sultan of Pahang in 1887, became the governor's agent there. After filling several other administrative posts, he returned to Pahang as British resident during the years 1896–99. Four years later he became colonial secretary at Trinidad, and was transferred in the same capacity to Ceylon in 1907, where he remained until his appointment as governor of the Gold Coast in 1912. He was governor of Nigeria, 1919–25; Ceylon, 1925–27; and the Straits Settlements, 1927–29. Apart from his career in the colonial service, Sir Hugh Clifford made his name as a writer of distinction, his stories of the Malay peninsula being among the best of his works of fiction. He married as his second wife the novelist, Mrs. Henry de la Pasture. Among his numerous works may be mentioned the following: *Studies in Brown Humanity* (1898); *Bush-Whacking* (1901); *Malayan Monochromes* (1913) and *The Further Side of Silence* (1916). Sir Hugh also compiled with Sir Frank Swettenham a *Dictionary of the Malay Language*. He retired from the colonial service in 1929 and died Dec. 19, 1941.

CLIFFORD, JOHN (1836–1923), British Nonconformist minister and politician, son of a warp-machinist at Sawley, Derbyshire, was born on Oct. 16, 1836. He worked in a lace factory where he attracted the notice of Baptists, who sent him to the academy at Leicester and the Baptist college at Nottingham to be educated for the ministry. In 1858 he was called to Praed Street chapel, Paddington (London), and while officiating there he attended University college and pursued his education at the British Museum. He took his B.A. (1861), B.Sc. (1862), M.A. (1864), and LL.B. (1866), and in 1883 he was given an honorary D.D. by Bates college, U.S.A. At Praed Street chapel he obtained a large following, and in 1877 Westbourne Park chapel was opened for him. As a preacher, writer, propagandist, and ardent Liberal politician he became a power in the Nonconformist body. He was president of the London Baptist Association in 1879, of the Baptist Union in 1888 and 1899, and of the National Council of Evangelical Churches in 1898. His prominence in politics dates from 1903, in consequence of his advocacy of "passive resistance" by non-payment of taxes to the Education Act of 1902. Into this movement he threw himself with militant ardour, his own goods being distrained upon, with those of numerous other Nonconformists. The "passive resistance" movement, with Dr. Clifford as its chief leader, contributed to the defeat of the Unionist Government in Jan. 1906, and his efforts were then directed to getting a new act passed which should be undenominational. The rejection of Mr. Birrell's bill in 1906 by the House of Lords led Dr. Clifford and his followers to denounce the House of Lords, but as year by year went by, up to 1909, with nothing but failure on the part of the Liberal ministry to solve the education problem —failure due not to the House of Lords but to the inherent difficulties of the subject—"passive resistance" lost its interest. Dr. Clifford received a C.H. in 1921, and died on Nov. 20, 1923.

His chief writings are *The English Baptists* (1881); *The Christian Certainties*, 2nd ed. (1904); *The Ultimate Problems of Christianity* (1906). *See* C. T. Bateman: *John Clifford* (1904); D. Crane: *John Clifford* (1908); *Life and Letters*, ed. by Sir James Marchant (1924).

CLIFFORD, NATHAN (1803–1881), U.S. supreme court justice, was born at Rumney, N.H., on Aug. 18, 1803. He read law in an office at Rumney and was admitted to the bar in 1827. Clifford settled in Maine and in 1830 was elected to the lower house of the state legislature. In 1834 he was appointed attorney general of the state and four years later was elected to the U.S. house of representatives. U.S. attorney general under Pres. James Polk, 1846–48, he also served as a diplomatic representative to Mexico at the end of the war with that country. From 1858 until his death on July 25, 1881, he was an associate justice of the U.S. supreme court.

Clifford became known as an able and articulate advocate of Jacksonian democracy. Although his early formal education was limited, he won wide respect for his comprehensive and learned legal opinions. His areas of special competence were maritime and commercial law and law pertaining to Mexican land grants and procedure and practice. Clifford did not write any of the court's majority opinions on leading points of constitutional law, however. Clifford, who headed the electoral commission which investigated the disputed Hayes-Tilden election of 1876, protested against its decisions in 1877 in favour of Rutherford Hayes, the Republican presidential candidate.

CLIFFORD, WILLIAM KINGDON (1845–1879), English mathematician and philosopher, was born on May 4, 1845, at Exeter. He was educated at King's college, London, and at Trinity college, Cambridge, where he was elected fellow in 1868. He was appointed professor of mathematics at University college, London, in 1871 and was elected a fellow of the Royal society in 1874. In 1875 he married Lucy (d. 1929), daughter of John Lane, of Barbados, who became well-known under her married name as a novelist and dramatist, her most successful story being *Mrs. Keith's Crime* (1885). A man of athletic but not robust physique, Clifford began to fall into ill-health in 1876 and, after two voyages to the south, died, during the third, of pulmonary consumption at Madeira, on March 3, 1879, leaving his widow with two daughters.

Clifford impressed all his contemporaries as a man of extraordinary originality; he had also quickness of thought and speech, a lucid style, wit, poetic fancy and social warmth. He was a mathematician of the front rank and, contrary to the excessively analytic tendency of the Cambridge mathematicians, "above all and before all a geometer." He developed the theory of biquaternions as a generalization of Sir W. R. Hamilton's quaternions and linked them with the general idea of a linear associative algebra. He recognized the serious difficulties created for Kant's theory of *a priori* synthetic propositions by the non-Euclidean geometries of Nikolai Lobachevski and Georg F. B. Riemann (*qq.v.*) and drew attention at the same time to the partly tautological character of arithmetic. He showed that spaces of constant curvature could have several different topological structures in the large and proved the topological equivalence of a Riemann surface to a box with holes in it. His suggestion (1870) that matter is a type of curvature of space foreshadowed Einstein's general theory of relativity. Other important papers of his dealt with Abelian functions, algebraic forms and projective and algebraic geometry.

Karl Pearson took up and developed further Clifford's views on the philosophy of science, which were related to those of Hermann von Helmholtz and Ernst Mach. In general philosophy, Clifford's name is chiefly associated with two phrases of his coining, "mind-stuff" and "the tribal self." The latter gives the key to his ethical view, which explains conscience and the moral law by the development in each individual of a "self" that prescribes the conduct conducive to the welfare of the "tribe." He was prominent in the battle between theology and Darwinian science.

His works are: *Elements of Dynamic* (1879–87); *Seeing and Thinking* (1879); *Lectures and Essays* (1879); *Mathematical Papers*, ed. by R. Tucker (1882); and *The Common Sense of the Exact Sciences*, completed by Karl Pearson (1885).

CLIFFSIDE PARK, a borough of Bergen county, N.J., U.S., on the Palisades overlooking the Hudson river. The railroad station is Weehawken (*q.v.*). A residential suburb, it had a population of 17,116 in 1950; 16,892 in 1940 by the federal census.

CLIFTON, a town of Arizona, U.S., on the San Francisco river and the Southern Pacific railway, near the eastern boundary of the state; the county seat of Greenlee county. Pop. (1950) 3,466; (1940) 2,668. It was formerly in the Morenci-Metcalf copper-mining district. Metcalf was abandoned and all the buildings removed. Morenci became the site of a large open-pit copper-mine development, to make available low-grade copper ore. Clifton was settled about 1870, and was incorporated in 1908. It is the oldest copper-mining camp in the state.

CLIFTON, a city of Passaic county, N.J., U.S., between Paterson and Passaic, served by the Delaware, Lackawanna and Western and the Erie railroads. Pop. (1950) 64,511. There are about 200 major industries manufacturing television sets, dry batteries and flashlights, electronic equipment, printing machinery, tire machinery, precision instruments and tools, calendars, chemicals, drugs, aircraft parts, steel springs, railroad boxcars, textiles and telephones. Production in 1950 was valued at $600,000,000. It has a city manager form of government.

CLIFTON FORGE, a city of western Virginia, U.S., amid the superb scenery of the Allegheny mountains, on the Jackson river; in Alleghany county, but administratively independent of it. It is on federal highways 60 and 220, and is served by the Chesapeake and Ohio railway. Pop. (1950) 5,795; (1940) 6,461. The city has railroad repair shops, is a distributing point for coal from the near-by fields and is headquarters of the western division of the Virginia Electric & Power company. Clifton Forge, formerly called Williamson, was incorporated in 1884. Iron Gate gap with the rainbow rock formation on either side, is the natural pass through the mountains formed by the river and used by travellers since Indian days. Douthat State park is near by.

CLIMACTERIC, a critical period in human life (from the Gr. *κλιμακτήρ*, the rung or step of a ladder); in a medical sense, the period known as the "change of life," marked in women by the menopause (*q.v.*). The word is also used of any turning point in the history of a nation, a career, etc.

CLIMATE, ARTIFICIAL. Climate usually signifies the external factors which affect animals and plants, such as solar radiation, humidity, gaseous composition of the air, temperature and air movement. The mechanical control of these factors constitutes artificial climate. In 1933 the John B. Pierce Laboratory of Hygiene was established in New York city for the study of man's relationship to his thermal environment both from the physical and physiological standpoints, marking the beginning of the modern approach to the science of air conditioning. That climatic conditions affect health is generally recognized, and records can be found showing increased mortality rates accompanying local periods of unseasonal weather such as the "hot week" of 1934 in the U.S. during which the death rate was doubled. That the human body periodically displays seasonal variations to climatic changes is shown by variations in blood chemistry, endocrine functions, resistance to infectious diseases and, as noted, even mortality.

The modern aspect of artificial climate regulation for animals and man involves primarily temperature, humidity and air movement: *i.e.*, it is physical more than chemical. As F. S. Lee pointed out, the major problems are physical rather than chemical, cutaneous rather than respiratory. Oversimplification of the problem is dangerous, however. Simple measurement of total heat exchange has been replaced by partitional calorimetry. Since heat production by the body is chemical and heat loss physical, the maintenance of body temperature becomes the balance between heat production (thermogenesis) and heat loss (thermolysis).

Man.—Of major importance to comfort is humidity. Under proper humidity conditions greater extremes of temperature can be tolerated by man, especially high temperatures. In dry air, for example, man has endured an external temperature of 164° F., which is high enough to cook meat.

The proper use of clothing aids man to keep comfortable in extremely warm or cold climates. If rate of air movement is adequate, relative humidity becomes less important at high temperatures. The lower room temperatures used in England are related to the heavier clothing worn and acclimatization. Up until about 1930–40, homes in the U.S. were less well heated, and heavier clothes were worn than in the following decades.

A. P. Gagge and his coworkers found that ideal comfort is experienced when three conditions are maintained—a skin temperature of 91.5° F., a minimum heat change in the body tissues and a minimum evaporative rate. An average person radiates enough heat to raise the temperature of 30 cu.ft. of air 9° F. per minute; thus air movement in public gathering places should be equivalent to 30 ft. per person per minute. The incoming air should be slightly cooler than the room air to remove the heat produced by the occupants. In modern homes with air conditioning it becomes necessary to humidify the air in winter by various means for best respiratory comfort. In summer, conversely, moisture should be removed from the air in many localities for best physiological comfort. Often humidity control alone is adequate for comfort. Relative humidity of from 55% to 60% is usually sought. In critical experiments by C. E. A. Winslow and L. P. Herrington the effect of humidity on the drying of mucous membranes of the nose and throat was measured. They found the absolute moisture content of the air and not the relative humidity to be the critical factor. Thus the air of the schoolroom in winter with 10% relative humidity at 70° F. is no more harmful to the child than outside air of 14° F. saturated with moisture. Based on the fact that the critical point for drying of the mucosae of the mouth is 0.40 in. vapour pressure, drying must occur at air temperatures below 53° F. with any moisture content, at 60° with less than 77% relative humidity, at 70° with less than 54% relative humidity, and at 80° with less than 39% relative humidity. D. H. K. Lee disagreed with the generally accepted opinion that a hot, moist climate tends to impair vigour in children. He compared the "ideal" climate of D. Brunt of 66° to 68° F. and 60% humidity with air-conditioned houses in the U.S. with temperatures up to 78° F. Man can be acclimatized to tropical climates with greater ease than generally expected once infectious tropical diseases are overcome.

Plants.—The artificial control of climate finds extensive use in the culture and storage of plants. Temperature and light are the factors most commonly controlled. Widespread use of such controls is made by the greenhouse industry, which covered nearly 1,000 ac. in the United States alone in 1950; and, in addition, temperature controls are used considerably in the storage of fruits and vegetables.

Storage facilities for horticultural products included more than 500,000 cu.ft. in the United States in 1950. Artificial climates also find an extremely valuable use in research relating to the growth and development of plants.

Temperature Control.—A wide variety of plant physiological processes are influenced by temperature, such as the rate of water evaporation from leaves, the rate of photosynthesis, the translocation of food materials and the type of metabolism carried out in the cells of the plant. Some crops require a high temperature for healthy growth, for example, Saintpaulia or African violet, which thrives only when temperatures are 70° F. or above. Others require low temperatures, especially at night. An example of this is the poinsettia, which is normally grown with day temperatures of from 75° to 85° F. and a night temperature of 60° F. It is very common for plants to require lowered temperatures at night. This requirement for a daily temperature cycle is termed thermoperiodism. The requirement for low night temperatures is thought to be a consequence of improved transport of food substances about the plant. Small plants commonly do not require a diurnal temperature function, apparently because transport is relatively unimportant to them. As the plant becomes larger, however, the diurnal temperature cycle is required.

Temperatures may be controlled for special physiological effects; *e.g.*, low temperatures are commonly used to bring about flowering in poinsettias or to increase the vigour of winter species of grains (a process called vernalization). High temperatures are used to hasten the flowering of many florist crops, particularly the spring bulbs.

Light Control.—A primary function of light is supplying the energy for photosynthesis, the basic source of all plant foods.

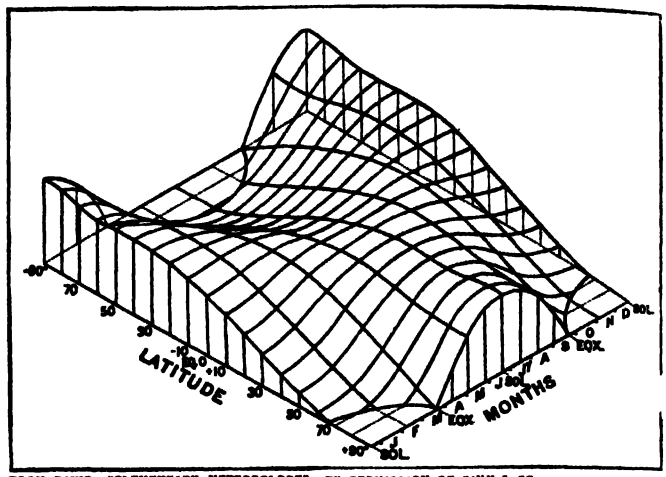
Artificial light is sometimes used to increase the light intensity in the culture of winter greenhouse crops. This practice is common in the low countries of northern Europe for the culture of greenhouse tomatoes. For other crops shading is frequently used to reduce light intensity in the summer. Large houses of cheesecloth are commonly erected in fields of tobacco for shading.

In greenhouses, however, light is artificially altered not so much for the photosynthetic effect as for the effects on plant development. As in the case of temperature, many plants are highly sensitive to the diurnal cycle of light and darkness. Some plants will flower only under cycles in which they experience short days and long nights, chrysanthemum and ragweed being common examples. Other plants require the opposite situation for flowering, in which they experience long days and short nights as do sugar beet, spinach and onions. Because of such sensitivity to day and night length (photoperiodism), artificial control of the length of day (or the length of night) can be used effectively to prevent or force flowering in many plants.

Research workers have discovered that the length of the night is generally the determining factor in responses to seasonal changes of day length both in plants and in animals. Hence long-day type of behaviour can be maintained by simply supplying a brief exposure to light in the middle of each long night. This technique is commonly used to prevent flowering of chrysanthemums and poinsettias until appropriate seasons for the advantageous sale in the winter. Chrysanthemums are commercially forced into early flowering for the autumn market by means of large tents of black cloth which are draped over the plants daily so as to give them the long night required for flowering.

Egg laying by chickens is carried on only under long-day conditions, and lights are used to extend the day in winter seasons when natural days are too short.

In artificial climates for the maintenance of plants in homes or business establishments it is generally sufficient to suspend 150-w. reflector-flood lights over the plants about 3 ft. from the foliage. For the growth of plants over longer periods of time, the filament type light bulb does not provide enough blue light, and hence a closely packed bank of fluorescent light bulbs is necessary as well. For disrupting the night period, very weak light intensities are sufficient. Some plants will not respond to long nights if they receive as little as 0.1 foot candle of light through the night. This intensity is only slightly above the maximum intensity of moonlight.



Other Factors.—Beside temperature and light, other factors of climate which are commonly controlled are humidity, air movement and the carbon dioxide content of the air. Humidity can be raised conveniently in greenhouses by spreading a porous material like coke over the ground and keeping this sprinkled with water. Mist nozzle sprayers are also used. Most fruits and vegetables wilt in storage if the humidity is below 85%. Air movement is controlled in the storage of fruit products known to emit gases which either alter the flavour or the maturation of the fruit itself. Rapid air movement is maintained commonly in apple storages to prevent accumulation of volatile gases, especially ethylene. Control of carbon dioxide is not usually carried out commercially even though large increases in plant growth can be obtained by increasing the air content of this gas. CLIMATE AND CLIMATOLOGY.

The word *clima* (from Gr. κλίνειν, to lean or incline) was used by the Greeks for the supposed slope of the earth towards the pole, or for the inclination of the earth's axis. A change of *clima* then meant a change of latitude. The latter was gradually seen to mean a change in atmospheric conditions as well as in length of day, and *clima* thus came to have its present meaning. "Climate" is the average condition of the atmosphere. "Weather" denotes a single occurrence, or event, in the series of conditions which make up climate. The climate of a place is thus in a sense its average weather. Climatology is the study or science of climates; it is a branch of the science of meteorology (*q.v.*).

Climatic Elements and Their Treatment.—Climatology has to deal with the atmospheric conditions which affect human

FROM DAVIS, "ELEMENTARY METEOROLOGY" BY PERMISSION OF GINN & CO.

FIG. 1.—CLIMATOLOGY: DIAGRAM OF RELATIVE AMOUNTS OF INSOLATION RECEIVED AT DIFFERENT LATITUDES IN DIFFERENT MONTHS
Latitudes are shown on left margin, months on right, and values by the vertical distance above the plane of the two margins

life, viz., temperature (including radiation); moisture (including humidity, precipitation and cloudiness); wind (including storms) and evaporation. Climate deals first with average conditions, but a satisfactory presentation of a climate must take account, also, of regular and irregular daily, monthly and annual changes, and of local departures, mean and extreme, from the average conditions The mean minimum and maximum temperatures or rainfalls of a month or a season are important data. Further, a determination of the frequency of occurrence of a given condition, or of certain values of that condition, is important, for periods of a day, month or year, as for example the frequency of winds according to direction or velocity; or of different amounts of cloudiness. The probability of occurrence of any condition, as of rain in a certain month, is also a useful thing to know.

Solar Climate.—Climate, in so far as it is controlled solely by the amount of solar radiation which any place receives by reason of its latitude, is called solar climate. Solar climate alone would prevail if the earth had a homogeneous land surface, and if there were no atmosphere. The relative amounts of insolation received at different latitudes and at different times at the upper limit of the earth's atmosphere, *i.e.*, without the effect of absorption by the atmosphere, are shown in fig. 1 after Davis. The latitudes are given at the left margin and the time of year at the right margin. The values of insolation are shown by the vertical distance above the plane of the two margins. At the Equator, where the day is always 12 hours long, there are two maxima of insolation at the equinoxes, when the sun is vertical at noon, and two minima at the solstices when the sun is farthest off the Equator. The values do not vary much through the year because the sun is never very far from the zenith, and day and night are always equal. As latitude increases, the angle of insolation becomes more oblique and the intensity decreases, but at the same time the length of day rapidly increases during the summer, and towards the pole of the hemisphere which is having its summer, the gain in insolation from the latter cause more than compensates for the loss by the former. The double period of insolation above noted for the equator prevails as far as about lat. 12° N. and S.; at lat. 15° the two maxima have united in one, and the same is true of the minima. At the pole there is one maximum at the summer solstice, and no insolation at all while the sun is below the horizon. On June 21 the Equator has a day 12hr. long, but the sun does not reach the zenith, and the amount of insolation is therefore less

than at the equinox. On the northern tropic, however, the sun is vertical at noon, and the day is more than 12hr. long. Hence the amount of insolation received at this latitude is greater than that received at the equinox at the Equator. From the tropic to the pole the sun stands lower and lower at noon, and the value of insolation would steadily decrease with latitude if it were not for the increase in the length of day. Going polewards from the northern tropic on June 21, the value of insolation increases for a time, because although the sun is lower, the number of hours during which it shines is greater. A maximum value is reached at about lat. 43½°N. The decreasing altitude of the sun then more than compensates for the increasing length of day, and the value of insolation diminishes, a secondary minimum being reached at about lat. 62°. Then the rapidly increasing length of day towards the pole again brings about an increase in the value of insolation, until a maximum is reached at the pole which is greater than the value received at the Equator at any time.

On June 21 there are therefore two maxima of insolation, one at lat. 43½° and one at the north pole. From lat. 43½° N., insolation decreases to zero on the Antarctic circle, for sunshine falls more and more obliquely, and the day becomes shorter and shorter. Beyond lat. 66½° S. the night lasts 24 hours. On Dec. 21 the conditions in southern latitudes are similar to those in the northern hemisphere on June 21, but the southern latitudes have higher values of insolation because the earth is then nearer the sun. At the equinox the days are equal everywhere, but the noon sun is lower and lower with increasing latitude in both hemispheres until the rays are tangent to the earth's surface at the poles (except for the effect of refraction). Therefore, the values of insolation diminish from a maximum at the Equator to a minimum at both poles.

The earth's atmosphere weakens the sun's rays. The more nearly vertical the sun, the less the thickness of atmosphere traversed by the rays. The values of insolation at the earth's surface vary with the condition of the air as to dust, clouds, water vapour, etc. As a rule, even when the sky is clear, about one-half of the solar radiation is lost during the day by atmospheric absorption. The great weakening of insolation at the pole, where the sun is very low, is especially noticeable. The following table (after Angot) shows the effect of the earth's atmosphere (coefficient of transmission 0·7) upon the value of insolation received at sea-level.

Values of Daily Insolation at the Upper Limit of the Earth's Atmosphere and at Sea-Level

Lat.	Upper limit of atmosphere			Earth's surface		
	Equator	40°	N. pole	Equator	40°	N. pole
Winter solstice	948	360	0	552	124	0
Equinoxes	1000	773	0	612	411	0
Summer solstice	888	1115	1210	517	660	494

These values are relative only; during the present century the Astrophysical Observatory of the Smithsonian Institution of Washington, under the direction of C. G. Abbot, has estimated the actual intensity of the sun's radiation at the limit of the earth's atmosphere as 1·95 gramme-calories per sq.cm. per minute. (See RADIATION, RAYS.) This value is termed the "solar constant," though it varies within about five per cent. on either side of this mean value. The value of 1,000 on the above scale represents about 940 gramme-calories per sq.cm. of horizontal surface.

Physical Climate.—The distribution of insolation explains many of the large facts of temperature distribution; for example, the decrease of temperature from Equator to poles; the double maximum of temperature on and near the Equator; the increasing seasonal contrasts with increasing latitude, etc. But the regular distribution of solar climate between Equator and poles which would exist on a homogeneous earth, whereby similar conditions prevail along each latitude circle, is very much modified by the unequal distribution of land and water; by difference of altitude; by air and ocean currents, by varying conditions of cloudiness and so on. The uniform arrangement of solar climatic belts arranged latitudinally is interfered with, and what is known as *physical climate* results. According to the dominant control we have solar, continental and marine, and mountain climates. In the first-named, latitude is the essential; in the second and third, the influence of land or water; in the fourth, the effect of altitude.

Classification of the Zones by Latitude Circles.—The five familiar zones are the so-called torrid, the two temperate and the two frigid zones. The torrid zone is limited north and south by the Tropics of Cancer and Capricorn, the Equator dividing the zone into two equal parts. The temperate zones are limited towards the Equator by the Tropics, and towards the poles by the Arctic and Antarctic circles. The two polar zones are caps covering both polar regions, and bounded on the side towards the Equator by the Arctic and Antarctic circles. These are really zones of solar climate. The tropical zone has the greatest annual amount and the least annual variation of insolation. Its annual range of temperature is very slight. Beyond the Tropics the contrasts between the seasons rapidly become more marked. The polar zones have the greatest variation in insolation between summer and winter. They also have the minimum amount of insolation for the whole year; their summer is so short and cool that the heat is insufficient for most forms of vegetation, especially for trees. The temperate zones are intermediate between the tropical and the polar in the matter of annual amount and of annual variation of insolation. Temperate conditions do not characterize these zones as a whole. They are rather the seasonal belts of the world.

Temperature Zones.—The astronomical classification of the zones serves very well for purposes of simple description, but a glance at any isothermal chart shows that the isotherms do not coincide with the latitude lines. In fact, in the higher latitudes, the former sometimes follow the meridians more closely than they do the parallels of latitude. Hence it has been suggested that the zones be limited by isotherms rather than by parallels of latitude, and that a closer approach be thus made to the actual conditions of climate. Supan[1] has suggested limiting the hot belt, which corresponds to, but is slightly greater than, the old torrid zone, by the two mean annual isotherms of 68° F—an isothermal line which approximately coincides with the polar limits of the

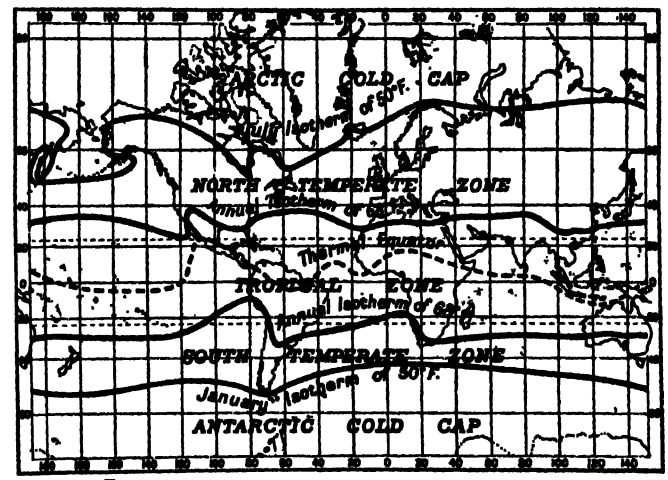

FIG. 2.—DIAGRAM SHOWING ZONES OF TEMPERATURE

trade-winds and with the natural distribution of palms. The limits of these zones, according to the most recent information, are shown in fig. 2. The hot belt widens somewhat over the continents, chiefly because there is a tendency towards an equalization of the temperature between Equator and poles in the oceans, while the stable lands acquire a temperature suitable to their own latitude. Furthermore, the unsymmetrical distribution of land in low latitudes of northern and southern hemispheres makes the hot belt

[1] A Supan, *Grundzüge der physischen Erdkunde* (Leipzig, 1896), 88–89. Also *Atlas of Meteorology*, Pl. 1.

extend farther north than south of the Equator. The polar limits of the temperate zones are fixed by the isotherm of 50° F for the warmest month. Summer heat is more important for vegetation than winter cold, and where the warmest month has a temperature below 50° F cereals and forest trees do not grow. The two polar caps are not symmetrical. Extended land masses in high northern latitudes carry the temperature of 50° F in the warmest month farther poleward there than is the case in high southern latitudes occupied by the oceans which warm less easily and are constantly in motion. Hence the southern cold cap, with equatorial limits at about lat. 50° S., is much larger than the northern polar cap. The northern temperate belt in which the great land areas lie is much broader than the southern belt, especially over the continents. These temperature zones emphasize the natural conditions of climate more than is the case in any subdivision by latitude circles, and they bear a fairly close resemblance to the old zonal classification of the Greeks.

Classification of Climates.—The best and most logical form of classification is one which takes account of all the different climatic elements. Such a scheme has been prepared by W. Köppen (*Die Klimate der Erde,* Berlin and Leipzig 1923) and assigns almost as much importance to rainfall as to temperature. Since the rainfall depends largely on prevailing winds, this classification also takes account of the zones of wind. Eight main zones are distinguished and divided and subdivided into a number of climatic provinces and smaller areas. Each subdivision is distinguished by a formula comprised of the main division followed by the initial letters of its characteristics: *e.g.,* the climate of Swakopmund is described as *BWkn,* which means a sub-tropical (B) desert (Wüste) climate with a cold (kalt) winter and frequent fog (Nebel). The eight zones are: A tropical rain zone with the coldest month usually above 64° F and rainfall above the limit of dryness (which varies according to the temperature and the seasonal distribution of rain); two zones of dry (steppe and desert) climate; two zones of warm temperate rain climate with the mean temperature of the coldest month between 64° and 27° F. (these include the "Mediterranean" and most of the "monsoon" climatic areas); a zone of "boreal" or snow and forest climate (with hot summers and cold winters below 27° F), which requires a large area of land and is consequently missing in the southern hemisphere; and two polar caps of "snow climate" with the mean temperature of the warmest month below 50° F.

Marine or Oceanic Climate.—Areas can also be classified climatically according to their position relative to the great land masses, and irrespective of their latitude. Land warms and cools readily, and to a considerable degree; water slowly and but little. The slow changes in temperature of the ocean waters involve retardation in times of occurrence of maxima and minima, and a marine climate, therefore, has cool spring and warm autumn, seasonal changes slight, a prevailingly higher relative humidity, a larger amount of cloudiness, and a heavier rainfall than is found over continental interiors. In middle latitudes oceans have distinctly rainy winters, while over continental interiors the colder months have minimum precipitation. Ocean air is cleaner and purer than land air and is generally in more active motion.

Continental Climate.—Annual temperature ranges increase, as a whole, with increasing distance from the oceans. The coldest and warmest months are usually January and July, times of maximum and minimum temperatures being less retarded than in marine climates. The greater seasonal contrasts in temperature over the continents than over the oceans are furthered by the smaller humidity and cloudiness over the former. Diurnal and annual changes of nearly all elements of climate, irregular as well as regular, are greater over continents than over oceans. Fig. 3 illustrates the annual march of temperature in marine and continental climates. Jacobabad in India (J), and Funchal on the island of Madeira (M) are representative continental and marine stations for a low latitude. Olekminsk in Siberia (Ol) and Lerwick in the Shetlands (L) are good examples of continental and marine climates of higher latitudes in the northern hemisphere.

Owing to distance from chief source of water vapour—the oceans—air over the larger land areas is drier and dustier than that over the oceans. Yet even in arid continental interiors in summer absolute vapour content is surprisingly large, and in the hottest months percentages of relative humidity may reach 20% or 30%; *e.g.,* in July, Luktschum with an average temperature of 90° and a relative humidity of 31 per cent. has more moisture in the air than Valentia with a temperature of 59° and a relative humidity of 83 per cent. Cloudiness, as a rule, decreases inland, and with this lower relative humidity, more abundant sunshine and higher temperature, the evaporating power of a continental climate in summer is much greater than that of the more humid, cloudier and cooler marine climate. Both amount and frequency of rainfall, as a rule, decrease inland, but conditions are very largely controlled by local topography and prevailing winds. Winds average somewhat lower in velocity, and calms are more frequent, over continents than over oceans. Seasonal changes of pressure over the former give rise to systems of inflowing and out-flowing, so-called continental, winds, sometimes so well developed as to become true monsoons. Extreme temperature changes over continents are the more easily borne because of the dryness of the air; because the minimum temperature of winter occurs when there is little or no wind, and because during the warmer hours of the summer there is the most air-movement.

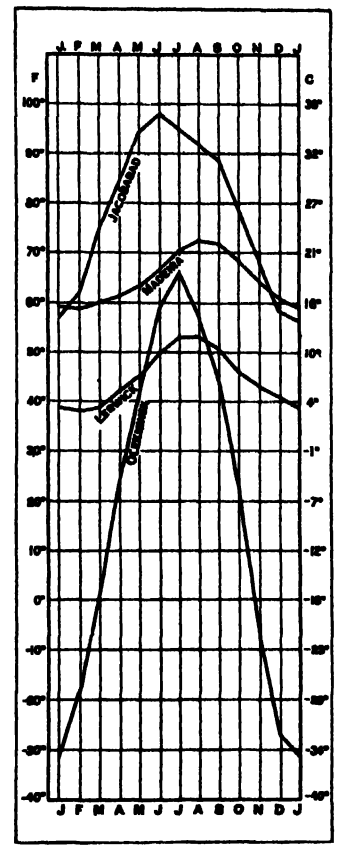

FIG. 3.—ANNUAL TREND OF AIR TEMPERATURE, SHOWING INFLUENCE OF CLIMATES IN LOW AND HIGH LATITUDES

Desert Climate.—Desert air is notably free from micro-organisms. The large diurnal temperature ranges of inland regions, which are most marked where there is little or no vegetation, give rise to active convectional currents during the warmer hours of the day. Hence high winds are common by day, while the nights are apt to be calm and relatively cool. Diurnal cumulus clouds, often absent because of excessive dryness, are replaced by clouds of blowing dust. Excessive diurnal ranges of temperature cause rocks to split and break up. Wind-driven sand erodes and polishes the rocks. When the separate fragments become small enough they, in their turn, are transported by the winds and further eroded by friction during their journey. Rivers "wither" away, or end in brackish lakes.

Coast or Littoral Climate.—Between pure marine and pure continental types coasts furnish almost every grade of transition. Prevailing winds are here important controls. When these blow from the ocean, climates are marine in character, but when they are off-shore, a modified continental climate prevails, even up to the immediate sea-coast. The former have smaller range of temperature; the air is damp, and there is much cloud. All these marine features diminish with increasing distance from the ocean, especially when there are mountain ranges near the coast. In the Tropics, windward coasts are usually well supplied with rainfall, and temperatures are modified by sea breezes. Leeward coasts in the trade-wind belts offer special conditions. Here deserts often reach the sea, as on the western coasts of South America, Africa and Australia. Cold ocean currents, with prevailing winds along-shore rather than on-shore, are here hostile to cloud and rainfall, although the lower air is often damp, and fog is common in these regions.

Monsoon Climate.—Exceptions to the general rule of rainier eastern coasts in trade-wind latitudes are found in monsoon regions, as in India, for example, where the western coast gets much rain from the south-west monsoon. As monsoons often sweep over large districts, not only coast but interior, a separate group of monsoon climates is desirable. In India there are really three seasons—the cool winter, the hot transition, and the wet summer monsoon. Little precipitation occurs in winter, and that chiefly in the northern provinces. The winter monsoon is normally off-shore and the summer monsoon on-shore, but exceptional cases are found where the opposite is true, as in north-east Ceylon. In higher latitudes the seasonal changes of the winds, although not truly monsoonal, involve differences in temperature and in other climatic elements. The only well-developed monsoons on the coast of the continents of higher latitudes are those of eastern Asia. These are off-shore during the winter, giving dry, clear and cold weather; while the on-shore movement in summer gives cool, damp and cloudy weather.

Mountain and Plateau Climate.—Temperature decreases upwards at an average rate of 3° per 1,000ft., and for this reason and also because of their obstructive effects, mountains are important climatic factors. Mountains as contrasted with lowlands are characterized by decrease in pressure, temperature and absolute humidity; increased intensity of insolation and radiation; usually greater frequency of, and up to a certain altitude more, precipitation. The highest habitations are about 16,000ft. above sea-level, at which altitude pressure has about half its sea-level value. The intensity of the sun's rays is very great in the cleaner, drier and thinner mountain air. Vertical decrease of temperature is especially rapid during warmer months and hours; mountains are then cooler than lowlands. The inversions of temperature characteristic of the colder months, and of the night, give mountains the advantage of a higher temperature then. At such times cold air flows down the mountain sides and collects in the valleys, being replaced by warmer air aloft. Hence diurnal and annual ranges of temperature on the mountain tops of middle and higher latitudes are lessened and the climate in this respect resembles the marine. High enclosed valleys often show continental conditions of large temperature range and such valleys in Europe open to the north-east form local "Siberias." Plateaus, as compared with mountains at the same altitude, have relatively higher temperatures and larger temperature ranges. Altitude tempers heat in low latitudes. High mountain peaks, even on the Equator, can remain snow-covered all the year round.

No general law governs variations of relative humidity with altitude, but on the mountains of Europe winter is the driest season, and summer the dampest. At well-exposed stations there is a rapid increase in the vapour content soon after noon, especially in summer. The same is true of cloudiness, often greater on mountains than at lower levels, and usually greatest in summer when it is least in the lowlands. The higher Alpine valleys in winter have little cloud. This, combined with their low wind velocity and strong sunshine and the night temperature inversions, makes them winter health resorts. Owing to forced ascent of air over rising ground, rainfall usually increases with height up to a certain point, beyond which, owing to loss of water vapour, this increase stops. The zone of maximum rainfall averages about 6,000ft. to 7,000ft. in altitude in intermediate latitudes, being lower in winter and higher in summer. When there is a prevailing wind from one direction, the lee side of the mountains, and the neighbouring lowlands, are relatively dry, forming a "rain shadow." Mountains resemble marine climates in having higher wind velocities than continental lowlands. Mountain summits have a nocturnal maximum of wind velocity, while plateaus usually have a diurnal maximum.

THE TORRID ZONE

Climate and Weather.—Climatic features here are simple and uniform. Periodic phenomena, depending upon the daily and annual march of the sun, are dominant; non-periodic weather changes are wholly subordinate. In special regions only, and at special seasons, is the regular sequence interrupted by an occasional tropical cyclone. These cyclones are comparatively infrequent and generally bring very heavy rains; the devastation one may produce often affects the economic conditions for many years.

Temperature.—Mean temperature is very high, and very uniform over the whole zone, with little variation during the year. The mean annual isotherm of 68° F. is a rational limit at the polar margins of the zone, and the mean annual isotherm of 80° F. encloses the greater portion of the land areas, as well as much of the inter-tropical oceans. The warmest latitude circle for the year is not the equator, but latitude 10° N. The highest mean annual temperatures, shown by the isotherm of 85°F., are in Central Africa, in India, the north of Australia and Central America, but, with the exception of the first, these areas are small. The temperatures average highest where there is little rain. In June, July and August there are large districts in the south of Asia and north of Africa with temperatures over 90° F.

Over nearly all the zone mean annual range of temperature is less than 10° F., and over much of it, especially on the oceans, less than 5° F. Even near the margins of the zone the ranges are less than 25° F., as at Calcutta, Hongkong, Rio de Janeiro and Khartoum. Mean daily range is usually larger than mean annual; "night is the winter of the Tropics." Over parts of the Pacific and Indian oceans from Arabia to the Caroline islands and from Zanzibar to New Guinea, as well as on the Guiana coast, minimum temperatures do not normally fall below 68° F. Towards the margins of the zone, however, the minima on the continents fall to or even below 32° F. Maxima of over 120° F. occur over the deserts of northern Africa and a reading of 136° F. at Azizia in Tunis is the highest known shade temperature. A district where the mean maxima exceed 113° F. extends from the western Sahara to north-western India, and over Central Australia. Near the Equator the maxima are not so high; and inter-tropical oceans show remarkably small variations in temperature.

The Seasons.—In a true inter-tropical climate the seasons depend not on temperature, but on rainfall and the prevailing winds. Life is regulated in some cases almost wholly by rainfall. Although the rain is characteristically associated with a vertical sun, that season is not necessarily the hottest. Towards the margins of the zone, with increasing annual ranges of temperature, seasons in the extra-tropical sense gradually appear. The association of uniformly high heat and humidity at most low-level places near the Equator is very enervating, and energetic physical or mental activity is difficult or impossible for white men. The absence of a bracing cold winter is a great drawback and the uniformity of conditions makes one sensitive to slight changes of temperature. The drier interior regions are more healthy, and the most energetic natives are the desert dwellers.

Pressure, Winds and Rainfall.—Pressure is lowest near the equator, in the belt of doldrums. Here the pressure gradients are small, and calms, variable winds and heavy rain and thunderstorms prevail. This region is one of the rainiest in the world, averaging about 100in., and the sky is generally cloudy; it includes the dense forests of the Amazon and equatorial Africa. The doldrums extend from the Equator to about 10° N., but do not include any part of the southern hemisphere; on either side are the belts of trade winds, the north-east trade from about 10° to 30° N. and the south-east trade from about 0° to 25° S. The trades are extremely regular and stable and except where they strike windward coasts or high mountains they bring fine bracing weather. Over oceans the skies show small detached clouds (trade cumulus) but over the western and central parts of the continents the trade wind latitudes are desert—the Sahara and Arabia, Kalahari and the desert of Australia. The boundaries between the trade winds and the doldrums move north and south following the sun, giving a "winter" dry season and a "summer" rainy season, which near the equator is divided into two by a minor dry season shortly after the summer solstice. Monsoons occur on many of the tropical lands, the best known being those of southern and eastern Asia. In the northern summer the south-west monsoon, warm and moist, blows over the latitudes from about 10°

N. to and beyond the northern tropic, between Africa and the Philippines, giving rains over India, the East Indian archipelago and the eastern coasts of China. In winter, the north-east monsoon, the normal cold-season outflow from Asia, combined with the north-east trade, and generally cool and dry, covers the same district, coming from as far north as lat. 30° N. Crossing the Equator, these winds reach northern Australia and the western islands of the South Pacific as a north-west rainy monsoon, while this region in the opposite season has the normal south-east trade. Other monsoons are found in the Gulf of Guinea and in equatorial Africa. Wherever they occur they control the seasonal changes.

The regular occurrence and cool, clean air of the sea breeze make many districts habitable for white settlers. On not a few coasts the sea breeze is a true prevailing wind. The location of dwellings is often determined by exposure of a site to the sea breeze.

Local thunderstorms are frequent, have a marked diurnal periodicity, find their best opportunity in the equatorial belt of weak pressure gradients and high temperature, and are commonly associated with the rainy season, being most common at the beginning and end of the regular rains. In many places intense thunderstorms occur daily throughout the rainy season.

Cloudiness.—The average cloudiness of the tropics does not differ greatly from that in temperate regions. The mean, in tenths of sky covered, is shown by the following table:—

Latitude	30°–20° N.	20°–10° N.	10°N–0°.	0°–10° S.	10°–20° S.	20°–30° S.
Land .	3·4	4·0	5·2	5·6	4·6	3·8
Sea . .	4·9	5·3	5·3	5·0	4·9	5·3
Mean .	4·1	4·7	5·3	5·2	4·8	4·8

Both wholly clear and wholly overcast days are rare in the Tropics; the sky is more usually about half clouded.

CLIMATIC SUBDIVISIONS

The Equatorial Belt.—Within a few degrees of the Equator and when not interfered with by other controls, the annual curve of temperature has two maxima following the two zenithal positions of the sun, and two minima at about the time of the solstices. This equatorial type of annual march of temperature is illustrated in the three curves for Brazzaville, Batavia and Ocean island (fig. 4). The greatest range is shown in the curve for Brazzaville, inland in the Congo valley; the curve for Batavia illustrates insular conditions with less range, and that for Ocean island oceanic conditions with a range of only 0·5° F.

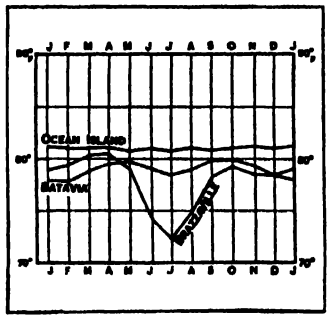

FIG. 4.—ANNUAL TREND OF TEMPERATURE FOR EQUATORIAL REGIONS
Heat for Brazzaville (Congo) is greatest

As the belt of rains swings back and forth across the Equator after the sun, there should be two rainy seasons with the sun vertical, and two dry seasons when the sun is farthest from the zenith, and while the trades blow. These conditions prevail on the Equator, and as far north and south of the Equator (about 10°–12°) as sufficient time elapses between the two zenithal positions of the sun for the two rainy seasons to be distinguished from one another. In this belt there is therefore normally no long dry season. The double rainy season is clearly seen in equatorial Africa and in parts of equatorial South America. The maxima lag somewhat behind the vertical sun, coming in April and November, and the first is the greater one. The minima are also unsymmetrically developed, and the so-called "dry seasons" are seldom wholly rainless. This rainfall type with double maxima and minima has been called the equatorial type, and is illustrated in the curves for Entebbe and Bogota (fig. 5). The annual totals are given. These double rainy and dry seasons are easily modified by other conditions, as by the monsoons of the Indo-Australian areas, so that there is no rigid belt of equatorial rains extending around the world. In South America, east of the Andes the distinction between rainy and dry seasons is often much confused. The annual variation of cloudiness is illustrated by the curve for Ocean island (Oc) in fig. 6, but the annual period varies greatly under local controls.

At greater distances from the Equator than about 10° or 12° the sun is still vertical twice a year within the Tropics, but the interval between these two dates is so short that the two rainy seasons merge into one, in summer, and there is also but one dry season, in winter. This is the so-called tropical type of rainfall, and is found where the trade belts are encroached upon by the equatorial rains during the migration of these rains into each hemisphere. It is illustrated in the curves for São Paulo, Brazil, and for the city of Mexico (fig. 5). The tropical type of rainfall occurs beyond the margins of the region of equatorial rainfall and as we go farther towards the lines of the tropics the rainy season shortens to four months or less, lowlands often become parched during the long dry season (winter), while life resumes activity when the rains return (summer). The Sudan receives rains, and its vegetation grows actively when the doldrum belt is north of the equator (May–August). But when the trades blow (December–March) the ground is parched and dusty. The Venezuelan *llanos* have a dry season in the northern winter, when the trade blows. The rains come in May–October. The *campos* of Brazil, south of the Equator, have their rains in October–April, and are dry the remainder of the year. The Nile overflow results from the rainfall on the mountains of Abyssinia during the northward migration of the belt of equatorial rains.

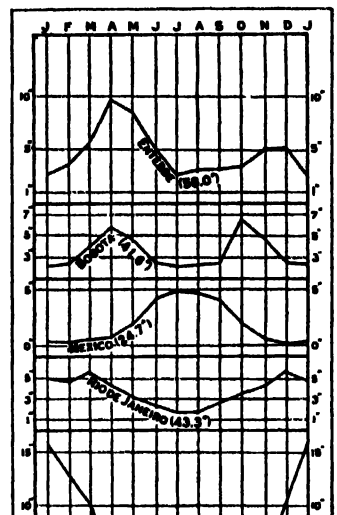

FIG. 5.—ANNUAL TREND OF RAINFALL IN TROPICS, TOTALS GIVEN IN INCHES

The so-called tropical type of temperature variation, with one maximum and one minimum, is illustrated in the accompanying curves for Wadi Halfa, in upper Egypt; Alice Springs, Australia; Nagpur, India; and St. Helena (fig. 7). The effect of the rainy season is often shown in a displacement of the time of maximum temperature to an earlier month than the usual one as at Nagpur.

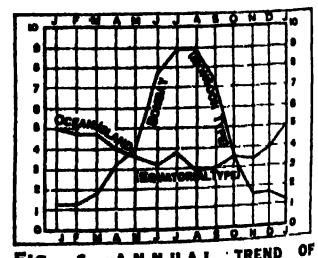

FIG. 6.—ANNUAL TREND OF CLOUDINESS IN TROPICS, WITH EFFECT OF MONSOON

Trade-Wind Belts.—The trade belts near sea-level have fair weather, steady winds, infrequent light rains or even an almost complete absence of rain, very regular, although slight, annual and diurnal ranges of temperature, and constancy and regularity of weather. The climate of ocean areas in the trade-wind belts is indeed the simplest and most equable in the world, the greatest extremes over these oceans being found to leeward of the larger lands. On the lowlands swept over by the trades, beyond the polar limits of the equatorial rain belt (roughly between lats. 20° and 30°), are most of the great deserts of the world. These deserts extend directly to the water's edge on the leeward western coasts of Australia, Africa and America. Ranges and extremes of temperature are much greater over continental interiors than

over oceans in trade-wind belts. Minima of 32° or less occur during clear, quiet nights, and daily ranges of over 50° are common. Midsummer mean temperature rises above 90°, with noon maxima of 110° or more in the non-cloudy, dry air of a desert day. The days, with high, dry winds, carrying dust and sand, with extreme heat, accentuated by absence of vegetation, are disagreeable, but the calmer nights, with active radiation under clear skies, are much more comfortable. Nocturnal temperatures are often low, and thin sheets of ice may form.

While the trades are drying winds as long as they blow strongly over the oceans, or over lowlands, they readily become rainy if cooled by ascent. Hence the windward eastern sides of mountains or bold coasts in the trade-wind belts are well watered, while the leeward sides, or interiors, are dry. Mountainous islands in the trades, like the Hawaiian islands, many of the East and West Indies, the Philippines, Borneo, Ceylon, Madagascar, Teneriffe, etc., show marked differences of this sort. The eastern coasts of Guiana, Central America, south-east Brazil, south-east Africa and eastern Australia are well watered, while the interiors are dry. South America in the south-east trade belt is not well enclosed on the east and the most arid portion is an interior district close to the eastern base of the Andes where the land is low. Even far inland the Andes again provoke precipitation along their eastern slopes and the narrow Pacific coastal strip to leeward of the Andes is a very pronounced desert from near the equator to about lat. 30° S. The cold ocean waters, with prevailing southerly (drying) winds alongshore, are additional factors causing this aridity. The rainfall associated with the conditions just described is known as the *trade* type, and has a maximum in winter when the trades are most active. In cases where the trade blows steadily throughout the year against mountains or bold coasts, as on the Atlantic coast of Central America, there is no real dry season. The curve for Hilo (mean annual rainfall 145·24 in.) on the windward side of the Hawaiian islands, shows typical conditions (*see* fig. 5).

Monsoon Belts.—In a typical monsoon region the rains follow the vertical sun, and therefore have a simple annual period much like that of the tropical type above described. This monsoon type of rainfall is well illustrated in the curve for Port Darwin in Australia (*see* fig. 5). This summer monsoon rainfall results from the inflow of a body of warm, moist air from the sea upon a land area, the rainfall being particularly heavy where the winds have to climb over high lands. In India, the precipitation is heaviest in Assam (where Cherrapunji, at the height of 4,455ft. in the Khasi hills, has a mean annual rainfall of between 400in. and 500in.), on the bold western coast of the peninsula (western Ghats) (120in. and over), and on the mountains of Burma (up to 226in.). In the rain-shadow of the western Ghats, the Deccan often suffers from drought and famine unless the monsoon rains are abundant and well distributed. The prevailing direction of the rainy monsoon wind in India is south-west; on the Pacific coast of Asia, it is south-east. This monsoon district is very large, including the Indian ocean, Arabian sea, Bay of Bengal, and adjoining continental areas; the Pacific coast of China, the Yellow and Japan seas and numerous islands from Borneo to Sakhalin on the north and to the Ladrone islands on the east. A typical temperature curve for a monsoon district is that for Nagpur, in the Deccan (fig. 7), and a typical monsoon cloudiness curve is given in fig. 6, the maximum coming near the time of the vertical sun, in the rainy season, and the minimum in the dry season.

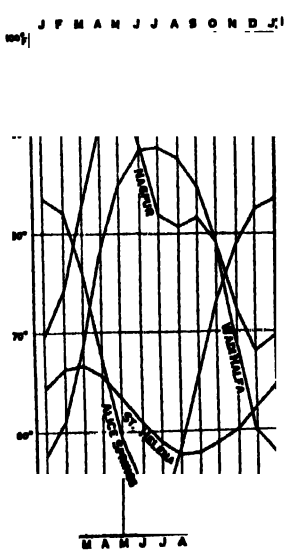

FIG. 7.—ANNUAL TREND OF TEMPERATURE: TROPICAL TYPE IN NORTHERN AND SOUTHERN HEMISPHERES

In the Australian monsoon region, which reaches across New Guinea and the Sunda islands, and west of Australia, in the Indian ocean, over latitudes 0°–10° S., the monsoon rains come with north-west winds between November and March or April. The general rule that eastern coasts between the Tropics are the rainiest finds exceptions in the case of the rainy western coasts in India and other districts with similar monsoon rains. On the coast of the Gulf of Guinea, for example, there is a small rainy monsoon area during the summer; heavy rains fall on the seaward slopes of the Cameroon Mountains where Debundscha averages 369 inches. Gorée, lat. 15° N., on the coast of Senegambia, gives a fine example of a rainy (summer) and a dry (winter) monsoon. In island groups such as the Malay Archipelago where trade winds alternate with monsoons the annual variation of rainfall becomes very complex.

Mountain Climate.—In the torrid zone altitude is chiefly important because of its effect in tempering the heat of the lowlands, especially at night. If mountains are high enough, they carry snow all the year round, even on the Equator. The highlands and mountains within the Tropics are thus often sharply contrasted with the lowlands, and offer more agreeable conditions in Africa and South America. In India, the hill stations are crowded during the hot months by Europeans. The climate of many tropical plateaus and mountains has the reputation of being a "perpetual spring." The rainfall between the Tropics on mountains and highlands often differs considerably in amount from that on the lowlands, and other features common to mountain climates the world over are also noted.

TEMPERATE ZONES

The designation "temperate" is appropriate for the middle latitudes of the southern hemisphere and of the oceans and western coasts in the northern hemisphere, but not for the continental interiors and eastern coasts of Asia and North America, for which Köppen's term "boreal" is better. The temperate zones as a whole are however characterized by the extreme changeableness of their weather, resulting from the frequent passage of barometric depressions.

Temperature.—The annual range of temperature exceeds the diurnal range in all parts of the temperate zone, but the former varies greatly from one part to another. It is smallest on windward islands and coasts and greatest in the interior of the continents, but nearer the east coasts than the west. Thus at Lerwick the range is 15° F from 38° F in February to 53° F in August, while at Iakutsk in Siberia it is 112° F from −46° F in January to 66° F in July, and the average difference between two consecutive months at Iakutsk is greater than the change in six months at Lerwick. Even at Vladivostok on the Pacific coast of Siberia the mean annual range is 61°. The southern part of the temperate zone in central Asia has very hot summers; thus Luktchun in 43° N. has a mean July temperature of 90° and a mean daily maximum in that month of 109°. Over much of the oceans of the temperate zones the annual range is less than 10°. In the south temperate zone there are no extreme ranges, the maxima, slightly over 30°, being near the margin of the zone in the interior of South America, Africa and Australia.

The north-east Atlantic and north-western Europe are about 35° too warm for their latitude in January, while north-eastern Siberia is 30° too cold. The lands north of Hudson bay are 25° too cold, and the waters of the Alaskan bay 20° too warm. In July, and in the southern hemisphere, anomalies are small. The diurnal variability of temperature is greater in the north temperate zone than elsewhere and the same month may differ greatly in its character in different years. The annual temperature curve has one maximum and one minimum. In the continental type the times of maximum and minimum are about one month behind the solstices. In the marine type the retardation may amount to nearly two months. Coasts and islands have a tendency to a cool spring and warm autumn; continents, to similar temperatures in both spring and autumn.

Pressure and Winds.—Over the oceans pressure decreases steadily from the sub-tropical anticyclones to the semi-permanent low pressure areas in about lat. 60°. Hence the prevailing winds are westerly but they are frequently disturbed by the passage of barometric depressions, and the wind may blow from any direction. In the northern hemisphere pressure is higher over the continents than over the oceans in winter, but higher over the oceans than the continents in summer. Hence winter is the stormiest season over the oceans and the prevailing winds become south westerly on the western coasts of the continents and northerly on the eastern coasts, while in summer they are north-westerly on the western and south-easterly on the eastern coasts. These seasonal changes are best developed on the eastern coast of Asia, where they have the regularity of true monsoons. The winter anticyclone of central Asia has produced the highest known readings of pressure. In the southern hemisphere the seasonal changes are less marked, owing to the preponderance of water, and between lat. 40° and 50° S. the winds blow from some westerly point with considerable regularity and force. These are the "roaring forties" or "brave west winds." Between 50° and 60° S. the winds, while still mainly westerly, are more irregular in direction owing to the frequent passage of storm-centres. Winter in these latitudes is stormier than summer, but seasonal difference is less than north of the Equator.

Rainfall.—Rainfall is fairly abundant over the oceans and also over a considerable part of the lands (30–80in. and more). It comes chiefly in connection with the usual cyclonic storms, or in thunderstorms. The variations, geographic and periodic, in rainfall produced by differences in temperature, topography, cyclonic conditions, etc., are very complex. The equatorial margin of the temperate zone rains is clearly defined on the west coasts, at points where coast deserts are replaced by belts of light or moderate rainfall. Bold west coasts, on the polar side of lat. 40°, are very rainy (100in. to 200in. a year in special situations). The hearts of the continents, far from the sea, especially when well enclosed by mountains, or when blown over by cool ocean winds which warm while crossing the land, have light rainfall (less than 20in.). East coasts are wetter than interiors but drier than west coasts. Autumn and winter are the seasons of maximum rainfall over oceans, islands and west coasts, for the westerlies are then most active, cyclonic storms are most numerous and best developed, and the relatively cold lands chill inflowing damp air. In winter, however, low temperatures, high pressures, and tendency to outflowing winds over continents are unfavourable to rainfall, and the interior land areas as a rule then have their minimum. The warmer months bring the maximum rainfall over the continents. Conditions are then favourable for inflowing damp winds from the adjacent oceans; there is the best opportunity for convection; thunder-showers readily develop on the hot afternoons; the capacity of the air for water vapour is greatest. The marine type of rainfall, with a winter maximum, extends in over the western borders of the continents, and is also found in the winter rainfall of the sub-tropical belts. Rainfalls are heaviest along the tracks of most frequent cyclonic storms. For continental stations the typical daily march of rainfall shows a chief maximum in the afternoon, and a secondary maximum in the night or early morning. The chief minimum comes between 10 A.M. and 2 P.M. Coast stations generally have a night maximum and a minimum between 10 A.M. and 4 P.M.

Humidity and Cloudiness.—Relative humidity is high (80–90%) over the oceans and western coasts and islands. On the eastern coasts and the neighbouring parts of the continents which come under the influence of the inblowing summer winds relative humidity is high in summer but low in winter. In the dry interior of the continents relative humidity is low (20–40%) in summer, though owing to the great heat the absolute humidity may be surprisingly high. In winter in the cold interiors the reverse holds; the absolute humidity is very low but the relative humidity comparatively high. Owing to difficulties of measurement at low temperatures, however, the data available are of doubtful accuracy.

The distribution of cloudiness resembles that of humidity, ranging from one-tenth in the interior deserts to nine-tenths in the oceanic storm areas. The averages for different latitudes are as follows:

Latitude	60°–50° N.	50°–40° N.	40°–30° N.	30°–40° S.	40°–50° S.	50°–60° S.
Land .	6·0	5·0	4·0	4·8	5·8	7·0
Sea . .	6·7	6·6	5·2	5·7	6·7	7·2
Mean .	6·2	5·6	4·5	5·4	6·6	7·2

Seasons in the temperate zones are classified according to temperature, not, as in the Tropics, by rainfall. The four seasons are important characteristics, especially of the middle latitudes of the north temperate zone. Towards the equatorial margins of the zones the difference in temperature between summer and winter becomes smaller, and the transition seasons weaken and even disappear. At the polar margins the change from winter to summer, and vice versa, is so sudden that there also the transition seasons disappear. These seasonal changes are of the greatest importance in the life of man. The monotonous heat of the Tropics and the continued cold of the polar zones are both depressing. The seasonal changes of the temperate zones stimulate man to activity and encourage higher civilization.

Climatic Subdivisions.—There are fundamental differences between north and south temperate zones. Marginal sub-tropical belts must also be considered as a separate group by themselves. The north temperate zone includes large and diverse areas of land, stretching over many degrees of latitude, as well as of water, and has a remarkable diversity of climates. Thus there are the ocean areas and the land areas. The latter are then subdivided into western (windward) and eastern (leeward) coasts and interiors. Mountain climates remain as a separate group.

South Temperate Zone.—Because of the large ocean surface, the régime in the south temperate zone is more uniform than in the northern. The south temperate zone may properly be called "temperate." Temperature changes are small, prevailing winds are stronger and steadier than in the northern hemisphere; seasons are more uniform; weather is prevailingly stormier, more changeable, and more under cyclonic control. The uniformity of the climatic conditions over the far southern oceans is monotonous. The continental areas are small, and develop to a limited degree only the more marked seasonal and diurnal changes which are characteristic of lands in general. Summers are less stormy than winters, but even summer temperatures are not high. New Zealand, with mild climate and fairly regular rains, is really at the margin of the zone, and has much more favourable conditions than the islands farther south, which have dull, cheerless climates. The zone enjoys a good reputation for healthfulness, which fact has been ascribed chiefly to the strong and active air movement and the cool summers. It must be remembered, also, that the lands are mostly in the sub-tropical belt, which possesses peculiar climatic advantages, as will be seen.

Sub-tropical Belts: *Mediterranean Climates.*—At the tropical margins of the temperate zones are the so-called sub-tropical belts. Their rainfall régime is alternately that of the westerlies and of the trades. In winter the equatorward migration of the great pressure and wind systems brings these latitudes under the control of the westerlies, whose frequent irregular storms give a moderate winter precipitation. These winter rains are not steady and continuous, but are separated by spells of fine sunny weather. The amounts vary greatly; much of the area has less than 20in., but Crkvice, on the Gulf of Cattaro, has 183 in. In summer, when the trades are extended polewards by the out-flowing equatorward winds on the eastern side of the ocean anticyclones, mild, dry and nearly continuous fair weather prevails, with northerly winds blowing towards the tropic.

Sub-tropical belts of winter rains and dry summers are mainly limited to western coasts of continents, and to the islands off these coasts in latitudes between about 28° and 40°. The sub-tropical belt is exceptionally wide in the Old World, and reaches far inland there, embracing countries bordering on the Mediterranean in southern Europe and northern Africa, and then extend-

ing eastward across the Dalmatian coast and the southern part of the Balkan peninsula into Syria, Mesopotamia, Arabia, north of the tropic, Persia and adjacent lands. This distribution has led to the use of the name "Mediterranean climate." Owing to great irregularity of topography and outline, the Mediterranean province embraces many varieties of climate, but the dominant characteristics are the mild temperatures, except on the heights, and the winter rains.

On the western coasts of the two Americas the sub-tropical belt of winter rains is clearly seen in California and in north Chile, on the west of the coast mountains. Between the region which has rain throughout the year from the stormy westerlies, and the districts which are permanently arid under the trades, there is an indefinite belt over which rains fall in winter. In south Africa, which is controlled by high pressure areas of the south Atlantic and south Indian oceans, the south-western coastal belt has winter rains, decreasing to the north while the east coast and adjoining interior have summer rains, from the south-east trade. Southern Australia is climatically similar to south Africa. In summer the trades give rainfall on the eastern coast decreasing inland. In winter the westerlies give moderate rains, chiefly on the south-western coast. Sub-tropical climates follow the tropical high pressure belts across the oceans, but do not retain their distinctive character far inland from the west coasts of the continents (except in the Mediterranean), nor on the east coasts. On the latter, summer monsoons and the occurrence of general summer rains interfere, as in east Asia and in Florida.

Strictly, winter rains are typical of the coasts and islands of this belt. The more continental areas have a tendency to spring and autumn rains. The rainy and dry seasons are most marked at the equatorward margins of the belt. With increasing latitude, the rain is more evenly distributed through the year, the summer becoming more and more rainy until, in the continental interiors of the higher latitudes, summer becomes the season of maximum rainfall. The monthly distribution of rainfall in two sub-tropical regions is shown in the accompanying curves for Malta and for Perth (Western Australia) (fig. 8). In Alexandria the dry season lasts nearly eight months; in Palestine from six to seven months; in Greece about four months. The winter rains which migrate equatorward are separated by the Sahara from the equatorial rains which migrate poleward. Large variations in annual rainfall may be expected towards the equatorial margins of sub-tropical belts.

The main features of the sub-tropical rains east of the Atlantic are repeated on the Pacific coasts of the two Americas. In North America the rainfall decreases from Alaska, Washington and northern Oregon southwards to lower California, and the length of the summer dry season increases. At San Diego, six months (May–October) have each less than 5% of the annual precipitation, and four of these have 1%. The southern extremity of Chile, from about latitude 38° S. southward, has heavy rainfall throughout the year from the westerlies, with a winter maximum. Northern Chile is persistently dry. Between these two there are winter rains and dry summers. Neither Africa nor Australia extends far enough south to show the different members of this system well. New Zealand is almost wholly in the prevailing westerly belt. Northern India is unique in having summer monsoon rains and also winter rains, the latter from weak cyclonic storms which correspond with sub-tropical winter rains.

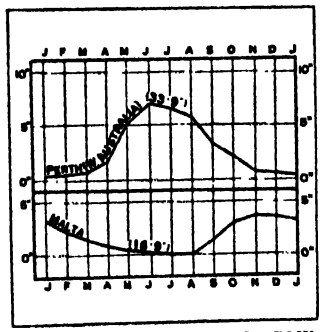

FIG. 8.—ANNUAL TREND OF RAINFALL, SUBTROPICAL TYPE, AT PERTH (W. AUSTRALIA) AND MALTA

From the position of the sub-tropical belts to leeward of the oceans, and at the equatorial margins of the temperate zones, it follows that their temperatures are not extreme. Further, the protection afforded by mountain ranges, as by the Alps in Europe and the Sierra Nevada in the United States, is an important factor in keeping out extremes of winter cold. The annual march and ranges of temperature depend upon position with reference to continental or marine influences (fig. 9). The Mediterranean basin is particularly favoured in winter, not only in the protection against cold afforded by the mountains, but also in the high temperature of the sea itself. The southern Alpine valleys and the Riviera are well situated, having good protection and a southern exposure. The coldest month usually has a mean temperature well above 32°. Mean minimum temperatures of about, and somewhat below, freezing occur in the northern portion of the district, and in the more continental localities such as northern Spain and the Balkans minima a good deal lower have been observed. Somewhat similar conditions obtain in the sub-tropical district of North America. Under the control of passing cyclonic storm areas, hot or cold winds, which often owe some of their special characteristics to the topography, bring into the sub-tropical belts, from higher or lower latitudes, unseasonably high or low temperatures. These winds have been given special names (mistral, sirocco, bora, etc.). Cloudiness is moderate in winter but very small in summer. The winter rains do not bring continuously overcast skies, and a summer month with a mean cloudiness of one tenth is not exceptional in the drier parts of the sub-tropics. With prevailing fair skies, even temperatures and moderate rainfall, the sub-tropical belts possess many climatic advantages which fit them for health resorts. The long list of well-known resorts on the Mediterranean coast, and the shorter list for California, bear witness to this fact.

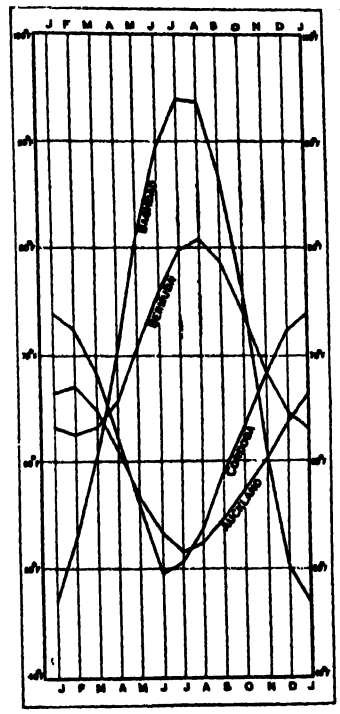

FIG. 9.—ANNUAL TREND OF TEMPERATURE FOR SELECTED SUBTROPICAL STATIONS

North Temperate Zone: *West Coasts:*—Marine climatic types are carried by the prevailing westerlies on to the western coasts of the continents, giving them mild winters and cool summers, abundant rainfall, and a high degree of cloudiness and relative humidity. North-western Europe is particularly favoured because of the remarkably high temperatures of the north Atlantic Ocean. January means of 40° to 50°F in the British Isles and on the northern French coast occur in the same latitudes as those of below 0° in the far interior of Asia. In July means of 60° to 70° in the former contrast with 70° to 80°F in the latter districts. The conditions are somewhat similar in North America. Along the western coasts of North America and of Europe the mean annual ranges are under 25°—actually no greater than some of those between the tropics. Irregular cyclonic temperature changes, are, however, marked in the temperate zone, while absent between the Tropics. The figures for the Scilly isles and for Thorshavn, Faröe islands, illustrate the insular type of temperature on the west coasts. The annual march of rainfall, with the slight maximum in the autumn and winter characteristic of the marine régime, is illustrated in the curve for north-western Europe (fig. 10). On the northern Pacific coast of North America the distribution is similar, and in the southern hemisphere the western coasts of southern America, Tasmania and New Zealand show the same type. The cloudiness and relative humidity average high on western coasts, with the maximum in the colder season.

Continental Interiors.—The equable climate of western coasts changes, gradually or suddenly, into the more extreme climates of the interiors. In Europe, where no high mountain ranges intervene, the transition is gradual, and broad stretches benefit by the tempering influences of the Atlantic. In North America the

change is abrupt and comes on crossing the lofty western mountain barrier. The figures in the accompanying table illustrate well the gradually increasing continentality of climate with increasing distance inland in Eurasia. Continental interiors of the north temperate zone have the greatest extremes in the world. Towards the arctic circle winters are extremely severe, and January mean temperatures of −10° and −20° are widespread. At the cold pole of north-east Siberia a January mean of −60° is found. Mean minimum temperatures of −40° occur in the area from eastern Russia, over Siberia and down to about latitude 50°N. Over no small part of Siberia minimum temperatures below −70° may be looked for every winter. Thorshavn and Yakutsk are excellent examples of temperature differences along the same latitude line. Fortunately in Siberia the lowest temperatures are always accompanied by calm weather. A temperature of 0° accompanied by a strong wind is harder to bear than −50° in a calm, and the gales (*buran, purga*), which carry loose snow, are very dangerous. North American winter weather in middle latitudes is often interrupted by cyclones, which, under the steep poleward temperature gradient then prevailing, cause frequent, marked and sudden changes in wind direction and temperature over the central and eastern United States. Cold waves and warm waves are common, and blizzards resemble the buran or purga of Russia and Siberia. With cold northerly winds, temperatures below freezing are carried far south towards the tropic.

The January mean temperatures in the southern portions of the continental interiors average about 50°. In summer the northern continental interiors are warm, with July means of 60° and thereabouts. These temperatures are not much higher than those on the west coasts, but as the northern interior winters are much colder than those on the coasts, the interior ranges are very large. Mean maximum temperatures of 86° occur beyond the Arctic circle in north-eastern Siberia, and beyond latitude 60° in North America. In spite of the extreme winter cold, agriculture extends remarkably far north in these regions, because of warm, though short summers, with favourable rainfall distribution. Summer heat is sufficient to thaw the upper surface of the frozen ground, and vegetation prospers for its short season; great stretches of flat surface become swamps. The southern interiors have torrid heat in summer, temperatures of over 90° being recorded in the south-western United States and in southern Asia. The diurnal ranges of temperature are very large, often exceeding 40°, and mean maxima exceed 110°.

The winter maximum of rainfall and cloud on the west coasts becomes a summer maximum in the interiors. The change is gradual in Europe, as is the change in temperature, but more sudden in North America. The rainfall curves for central Europe and for northern Asia illustrate these continental summer rains (*see* fig.10). The summer maximum becomes more marked with increasing continental character of the climate. There is also a well-marked decrease in the amount of rainfall inland. In western Europe rainfall averages 20in. to 30in., with much larger amounts (reaching 120in. and even more) on bold west coasts, as in the British Isles and Scandinavia, where moist Atlantic winds are deflected upwards, and also locally on mountain ranges, as on the Alps. There are small rainfalls (below 20in.) in eastern Scandinavia and on the Iberian peninsula. Eastern Europe has generally less than 20in., western Siberia about 15in., and eastern Siberia about 10in. In the southern part of the great overgrown continent of Asia an extended region of steppes and deserts, too far from the sea to receive sufficient precipitation, shut in, furthermore, by mountains, controlled in summer by drying northerly winds, receives less than 10in. a year, and in places less than 5in.

The North American interior because of its small area has more favourable rainfall conditions than Asia. The heavy rainfalls on the western slopes of the Pacific coast mountains correspond, in a general way, with those on the western coast of Europe. The coast mountains cause a much more rapid decrease of rainfall inland than in Europe and a considerable south-western interior region has deficient rainfall (less than 10in.). The eastern part of the continent is freely open to the Atlantic and the Gulf of Mexico, so moist cyclonic winds have access, and rainfalls of over 20in. are found everywhere east of the 100th meridian. These conditions are much more favourable than those in eastern Asia. The greater part of the interior of North America has the usual warm-season rains. In the interior basin, between the Rocky and Sierra Nevada mountains, the higher plateaux and mountains receive much more rain (largely from thunderstorms) than the desert lowlands. Forests grow on the higher elevations, while irrigation is necessary for agriculture below. In southern South America the narrow Pacific slope has heavy rainfall (over 80in.); east of the Andes the plains are dry (mostly less than 10in.). The southern part of the continent is very narrow, and is open to the east as well as more open to the west owing to decreasing height of the mountains. Hence the rainfall increases somewhat to the south with passing cyclones. Tasmania and New Zealand have most rain on their western slopes.

East Coasts.—Prevailing winds carry the interior continental climates off over the eastern coasts of the temperate zone lands and even on to the adjacent oceans. The east coasts therefore have continental climates, with modifications resulting from the presence of the oceans to leeward, and have little in common with the west coasts. On west coasts of north temperate lands isotherms are far apart. On east coasts they crowd together. The east coasts share with the interiors large annual and cyclonic ranges of temperature. A glance at isothermal maps of the world will show at once how favoured, because of its position to leeward of the warm North Atlantic waters, is western Europe as compared with eastern North America. A similar contrast, less marked, is seen in eastern Asia and western North America. In eastern Asia coast mountains give some shelter from extreme cold of the interior, but in North America, with no such barrier, severe cold winds sweep across the Atlantic coast States, even far to the south. Owing to prevailing offshore winds, oceans to leeward have relatively little effect.

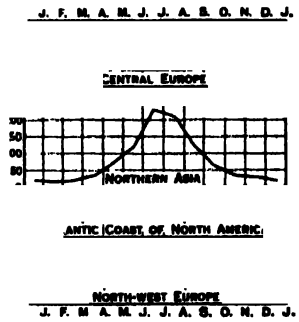

FIG. 10.—ANNUAL TREND OF RAINFALL IN NORTH TEMPERATE ZONE, IN THOUSANDTHS OF ANNUAL TOTALS

The rainfall increases from the interiors towards the east coasts. In North America the distribution through the year is very uniform, with some tendency to a summer maximum, as in the interior (N. A. fig.10). In eastern Asia winters are relatively dry and clear, under the influence of the cold offshore monsoon, and summers are warm and rainy. Rainfalls of 40in. are found on the east coasts of Korea, Kamchatka and Japan, while in North America, which is more open, they reach farther inland. Japan, although occupying an insular position, has a modified continental

rather than a marine climate. The winter monsoon after crossing the water, gives abundant rain and snow on the western coast, while the winter is relatively dry in the lee of the mountains, on the east. Japan has smaller temperature ranges than the mainland.

Mountain Climates.—If the altitude is sufficient, decreased temperature gives mountains a polar climate, with the difference that summers are relatively cool while winters are mild owing to inversions of temperature in anticyclonic weather. Hence annual ranges are smaller than over lowlands. At such times of inversion mountain-tops often appear as local areas of higher temperature in a general region of colder air over valleys and lowlands. Increased intensity of insolation aloft is important for certain mountain resorts in winter (*e.g.*, Davos and Meran). Of Meran it has been well said that from December to March the nights are winter, but the days are mild spring. The diurnal ascending air currents of summer usually give mountains their maximum cloudiness and highest relative humidity in the warmer months, while winter is the drier and clearer season.

CHARACTERISTICS OF THE POLAR ZONES

The temperate zones merge into the polar zones at the Arctic and Antarctic circles, or, if temperature be used as the basis of classification, at the isotherms of 50°F for the warmest month, as suggested by Supan. The longer or shorter absence of the sun gives the climate a peculiar character. Beyond the isotherm of 50°F for the warmest month forest trees and cereals do not grow. In the northern hemisphere this line is well north of the Arctic circle, in the continental climate of Asia, and north of it also in north-western North America and in northern Scandinavia, but falls well south in eastern British America, Labrador and Greenland, and also in the north Pacific Ocean. In the southern hemisphere this isotherm crosses the southern extremity of South America, and runs fairly east and west around the globe. There is a minimum of life, but more in the north polar than the south polar zone. Plants and land animals are few. Farming and cattle raising cease. Population is small and scattered. Man seeks his food chiefly in the sea and lives near the sea-coast. There are no permanent settlements at all within the Antarctic circle. Interior lands are deserted. Arctic vegetation must make rapid growth in the short, cool summer. In the highest latitudes summer temperatures are not high enough to melt snow on a level. Arctic plants grow and blossom rapidly and luxuriantly where the exposure is favourable, and the water from melting snow can run off; the soil then dries quickly and can be effectively warmed. Protection against cold winds is another important factor. Over great stretches of the northern plains the surface only is thawed out in the warmer months, and swamps, mosses and lichens are found over perpetually frozen ground.

Temperature.—At the solstices the two poles receive the largest amounts of insolation which any part of the earth's surface ever receives. Temperatures do not follow insolation in this case because much of the latter never reaches the earth's surface and because much energy which does reach the surface is expended in melting snow and ice of the polar areas. In the winter months there are three cold poles, in Siberia, in Greenland and at the pole itself. In January the mean temperatures at these three cold poles are −49°, −40° and −40° F respectively. The Siberian cold pole becomes a maximum of temperature during the summer, but the Greenland and polar minima remain throughout the year. In July the temperature distribution shows considerable uniformity; the gradients are relatively weak. A large area in the interior of Greenland, and one of about equal extent around the pole, are within the isotherm of 32°. For the year a large area around the pole is enclosed by the isotherm of −4°, with an isotherm of the same value in the interior of Greenland. The annual range of temperature is about 120° in Siberia, 80° in North America, 76° at the North Pole and 72° in Greenland. The North Pole obviously has a continental climate.

For the Antarctic our knowledge is still very fragmentary, and relates chiefly to summer months. Meinardus has determined mean temperatures of higher southern latitudes as follows:—

Mean Temperatures of High Southern Latitudes

S. Lat.	50°	60°	70°	80°
Mean Annual	41·9F	24·6F	8·1F	−12·5F
January	46·9	34·2	29·7	18·7
July	37·4	13·5	−11·0	−33·3

The whole southern hemisphere is colder than the northern. Antarctic summers are decidedly cold. Mean annual temperatures are about 10°, and minima of an ordinary Antarctic winter go to −40° and below, but so far no minima of the severest Siberian intensity have been noted. Maxima have varied between 35° and 50°. Temperatures at the South Pole itself suggest interesting speculations. It is likely that near the South Pole will prove to be the coldest point on the earth's surface for the year, as the distribution of insolation implies and as the conditions of land, ice and snow there suggest. The lowest winter and summer temperatures in the southern hemisphere will probably be found near the pole. Isotherms in the antarctic region bend polewards and equatorwards at different meridians, although much less so than in the Arctic.

The annual march of temperature in the north polar zone, for which we have the best comparable data, is peculiar in having a much retarded minimum in February or even in March—the result of the long cold winter. Temperature rises rapidly towards summer, reaching a maximum in July. Autumn is warmer than spring. The continents do not penetrate far enough into the Arctic zone to develop a pure continental climate in the highest latitudes. Verkhoyansk, latitude 67° 33′N., has an exaggerated continental type for the margin of the zone, with an annual range of 120°. One-third as large a range is found on Novaya Zemlya. Polar climate as a whole has large annual and small diurnal ranges, but sudden changes of wind may cause marked irregular temperature changes especially in winter. The smaller ranges are associated with greater cloudiness, and vice versa.

Pressure and Winds.—Pressure and winds follow a simpler scheme in the southern than in the northern hemisphere, because of the large extent of ocean. The southward decrease of pressure in temperate latitudes, previously described, ceases in about 60°S., where a trough of low pressure encircles the globe, widening somewhat over the Ross and Weddell Seas, while still farther south pressure rises again. On the northern side of this trough westerly winds prevail, on the southern side easterly winds. Over the Antarctic continent itself periods of calm, and, in winter, intense cold alternate with periods of high winds, which often develop into blizzards. Blizzards are not equally developed on all parts of the Antarctic coast, their frequency depending on the local topography and distribution of pressure; they are especially numerous in Adelie Land. Winds of any force sweep away the surface layer of cold air and cause a marked rise of temperature. They whirl up the loose surface snow but are also accompanied by fresh snow, and visibility is limited to a few yards.

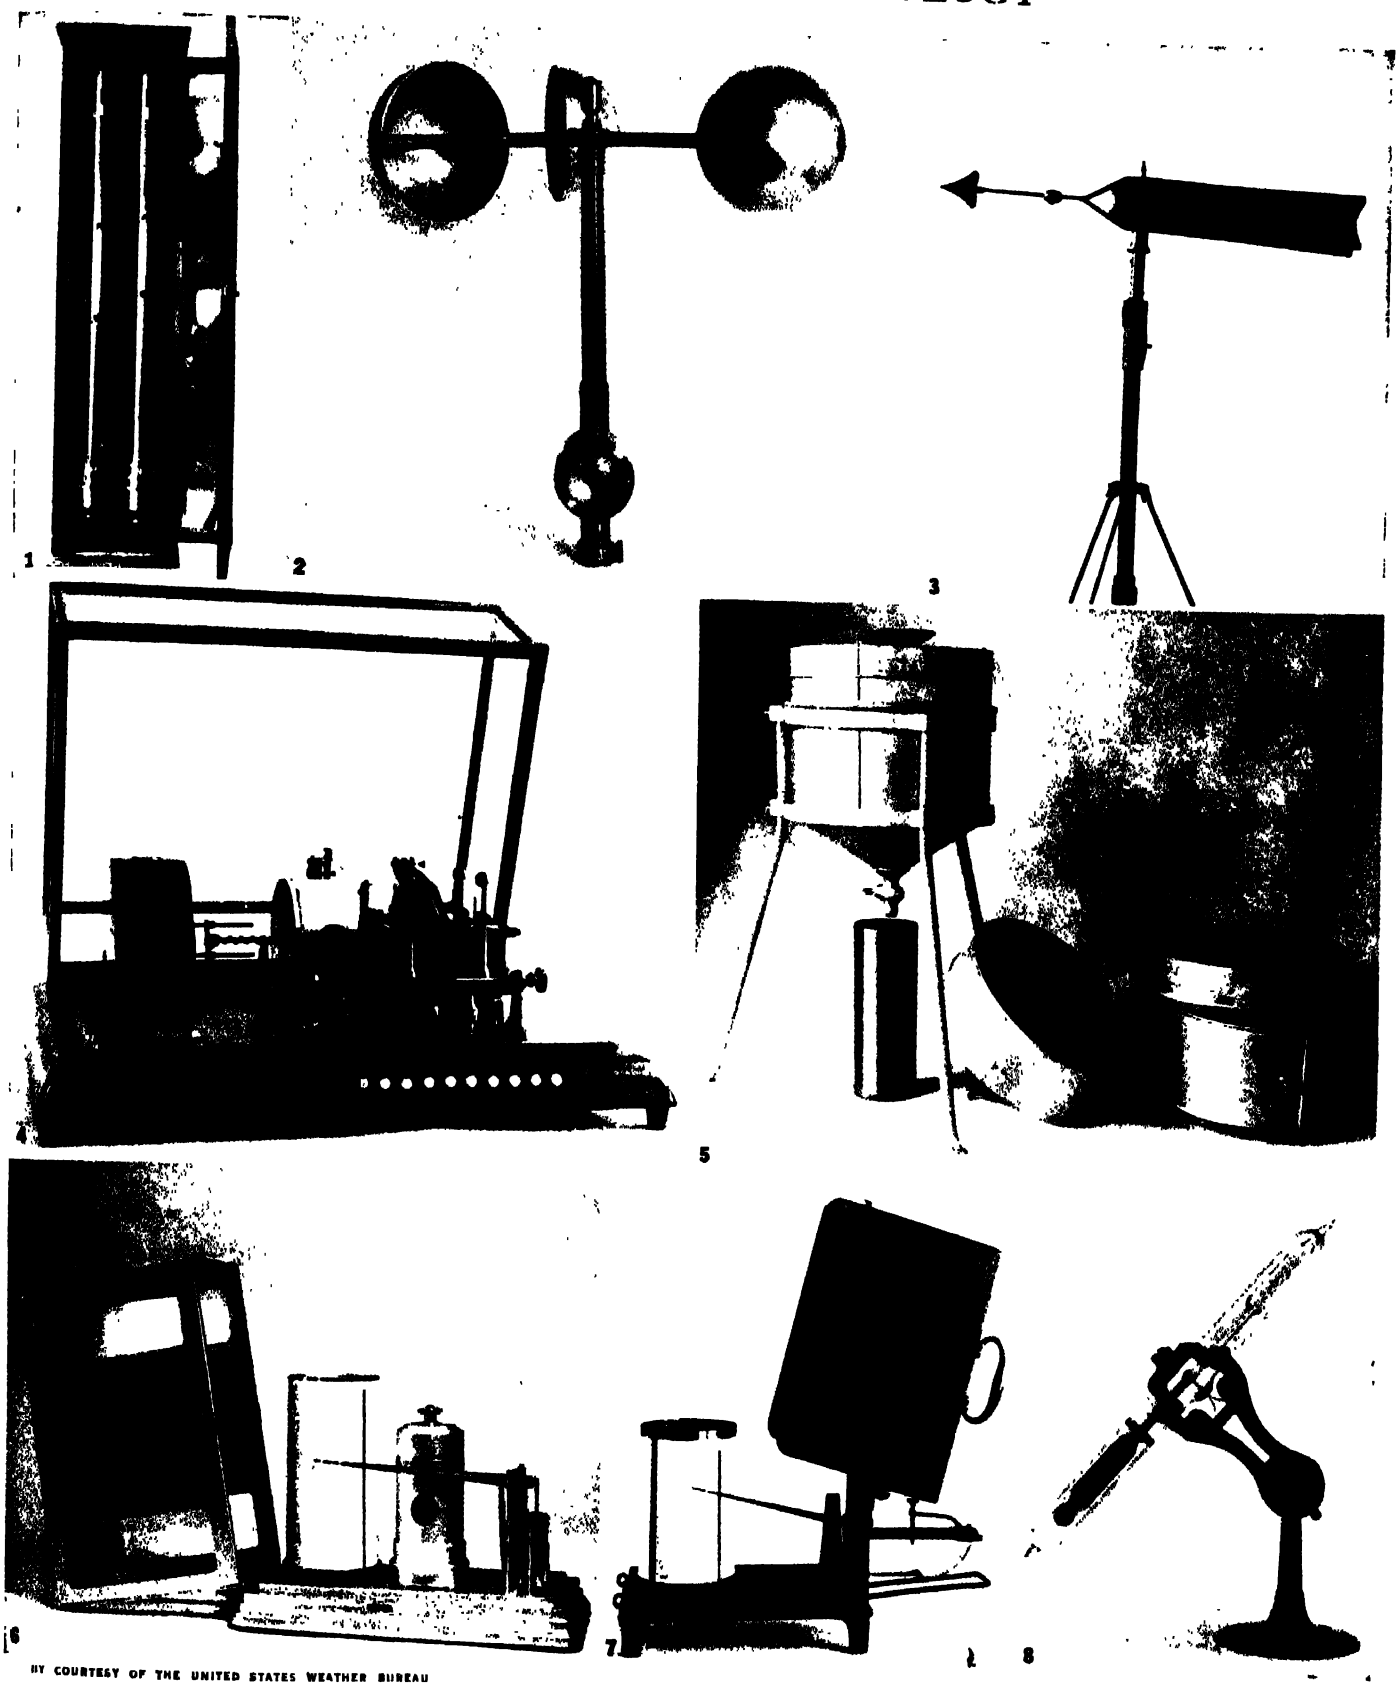
In the Arctic area wind systems are less clearly defined and pressure distribution is much less regular, on account of irregular distribution of land and water. The North Atlantic low-pressure area is more or less well developed in all months. Except in June, when it lies over Southern Greenland, this tongue-shaped trough of low pressure lies in Davis strait, to the south-west or west of Iceland, and over the Norwegian sea. In winter it greatly extends its limits farther east into the inner Arctic ocean, to the north of Russia and Siberia. The Pacific minimum of pressure is found south of Bering strait and in Alaska. Between these two regions a ridge of higher pressure extends from North America to eastern Siberia. This has been called by Supan the *"Arktische Windscheide."* Pressure gradients are steepest in winter. The prevailing westerlies which in the high southern latitudes are so symmetrically developed, are interfered with by the varying pressures over the northern continents and oceans in summer and winter. Isobaric and wind charts show that on the whole winds blow out from the inner polar basin, especially in winter and spring.

Rain and Snow.—The amount of precipitation is comparatively slight in the polar zones, chiefly because of the small capacity of the air for water vapour at the low temperatures there prevailing; partly also because of the rarity of local convectional

storms and thunder-showers. Even cyclonic storms cannot yield much precipitation. Extended snow and ice fields tend to give an exaggerated idea of the actual amount of precipitation. It must be remembered, however, that evaporation is slow at low temperatures, and melting is not excessive. Hence the polar store of fallen snow is well preserved; interior snowfields, ice sheets and glaciers are produced. The commonest form of precipitation is naturally snow, the summer limit of which, in the northern hemisphere, is near the Arctic circle, with the exception of Norway. So far as exploration has yet gone into the highest northern latitudes, rain falls in summer, but probably over most of the Antarctic continent rain never falls. The snow of the polar regions is characteristically fine and dry. At low polar temperatures flakes of snow are not found, but precipitation is in the form of ice spicules. The finest glittering ice needles often fill the air even on clear days, and in calm weather, and, gradually descending to the surface, slowly add to the depth of snow on the ground. Dry snow is also blown from the snowfields on windy days, interfering with the transparency of the air.

Humidity, Cloudiness and Fog.—Absolute humidity is low in polar latitudes, especially in winter, on account of low temperatures. Relative humidity varies greatly, and very low readings have often been recorded. Cloudiness seems to decrease somewhat towards the inner polar areas, after passing the belt of high cloudiness in the higher latitudes of the temperate zones. In marine climates of high latitudes summer has the maximum cloudiness; winter is clearer. The summer maximum is associated with fogs, produced where warm, damp air is chilled by contact with ice. They are also formed over open waters, as among the Faroe islands, for example, and open water spaces, in the midst of an ice-covered sea, are commonly detected at a distance by means of "steam fog." Fogs are less common in winter, when they occur as radiation fogs, of no great thickness. The small winter cloudiness, reported also from the Antarctic zone, corresponds with low absolute humidity and small precipitation. Coasts and islands bathed by warm water of the Gulf Stream drift are usually more cloudy in winter than in summer. The place of fog is in winter taken by fine snow crystals, which often darken the air like fog when strong winds raise the dry snow from the surfaces on which it is lying. Cumulus cloud forms are rare, even in summer. Stratus is probably the commonest cloud of high latitudes, often covering the sky for days without a break.

Physiological Effects.—The north polar summer, in spite of its lack of warmth, is in some respects pleasant and healthful, but the polar night is monotonous, depressing and repelling. Sir W. E. Parry said that it would be difficult to conceive of two things which are more alike than two polar winters. An everlasting uniform snow covering, rigidity, lifelessness and silence—except for the howl of the gale or the cracking of the ice. Small wonder that the polar night has sometimes unbalanced men's minds. The first effects are often a strong desire for sleep and indifference. Later effects have been sleeplessness and nervousness, tending in extreme cases to insanity, anaemia and digestive troubles. Extraordinarily low winter temperatures are easily borne if the air be dry and still. Zero weather seems pleasantly refreshing if clear and calm. But high relative humidity and wind —even a light breeze—give the same degree of cold a penetrating feeling of chill which may be unbearable. Large temperature ranges are endured without danger in the polar winter when the air is dry. Under direct insolation skin burns and blisters; lips swell and crack. Thirst has been much complained of by polar explorers, and is due to the active evaporation from the warm body into the dry, relatively cold air. Polar air is singularly free from micro-organisms owing to lack of communication with other parts; hence many diseases common in temperate zones, "colds" among them, are rare.

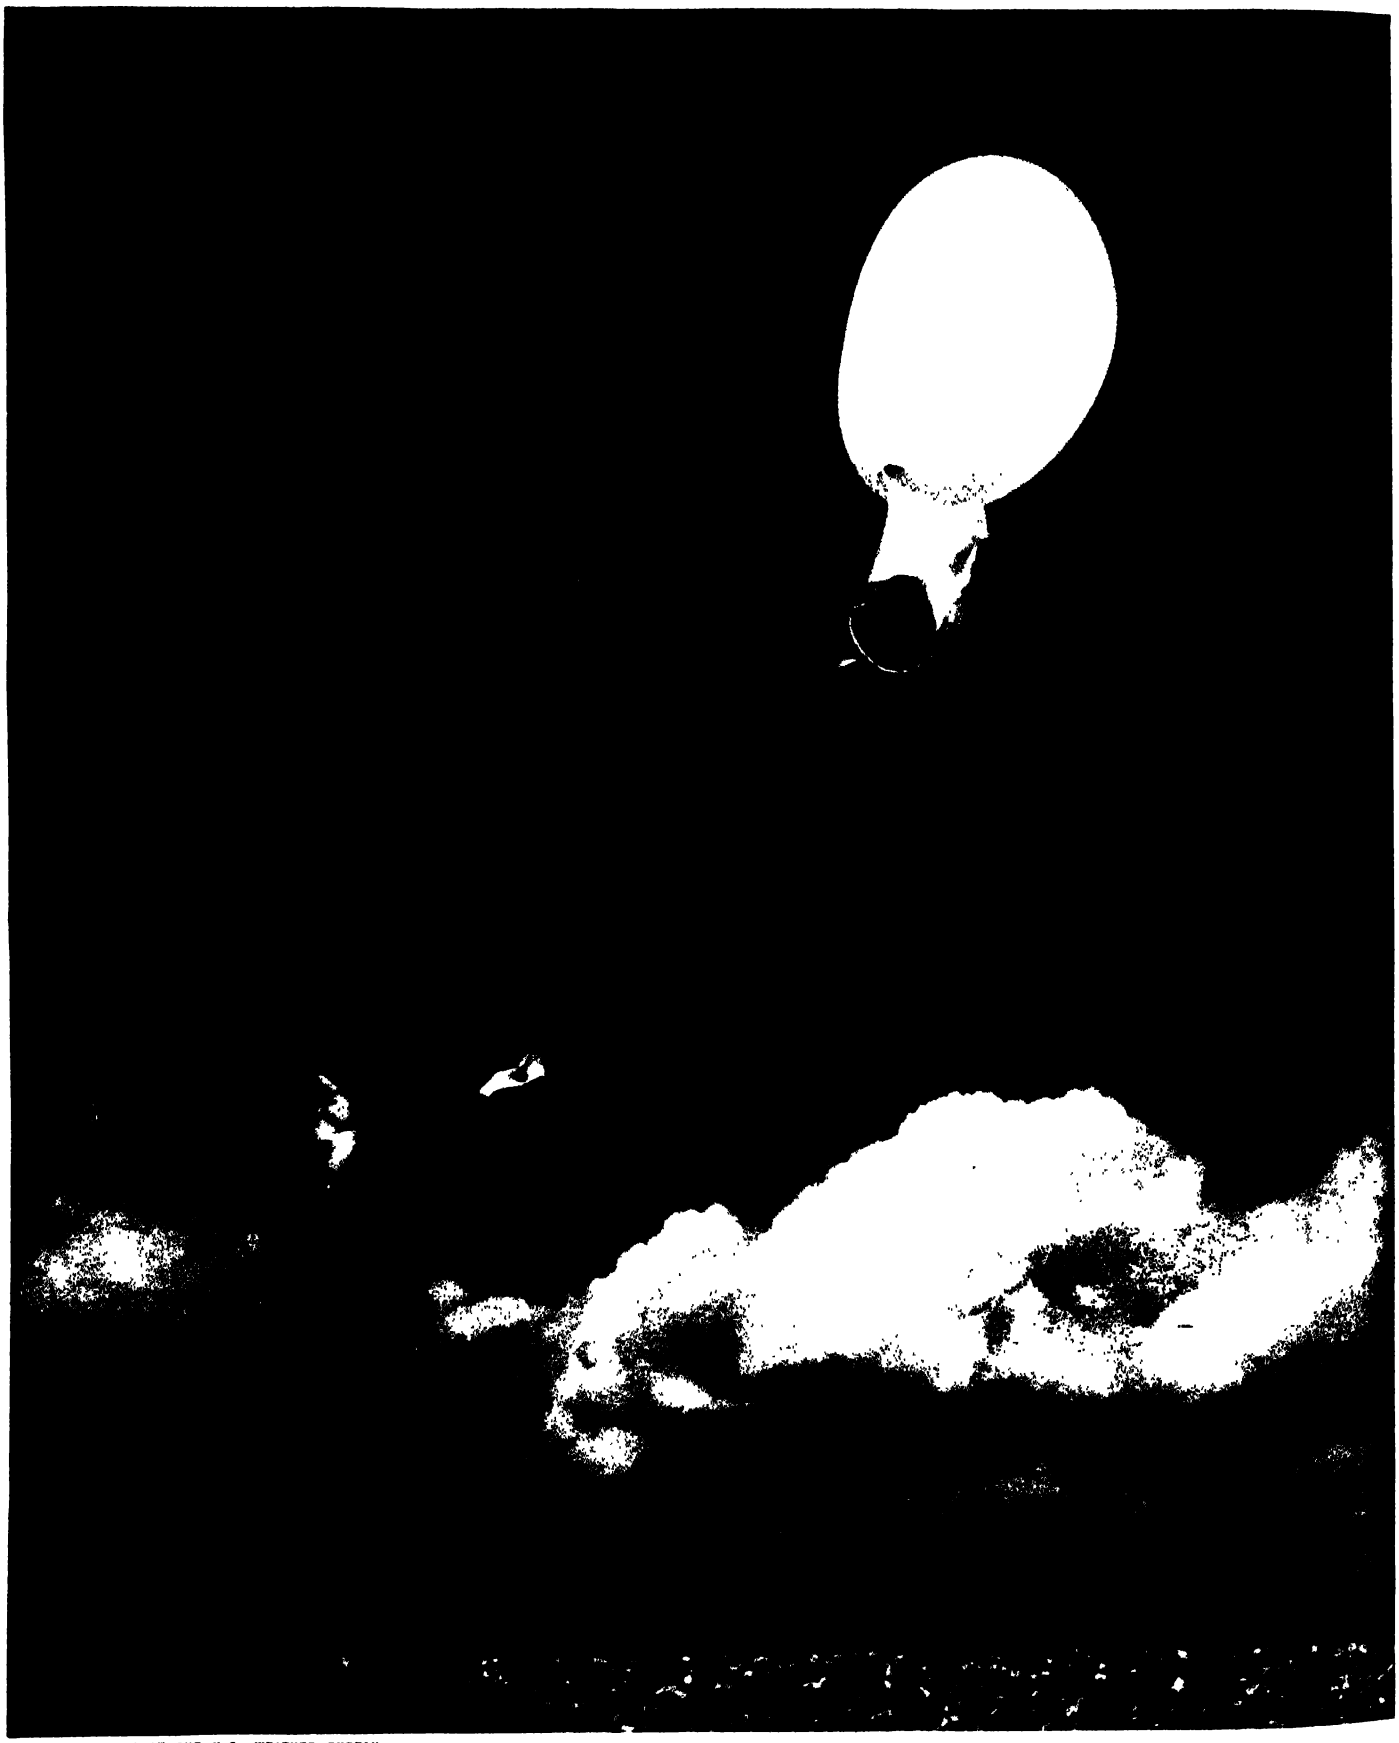


Changes of Climate.—The climatic divisions of the world appear to be constant in their broad outlines, but are subject to minor fluctuations which have a duration from a few years up to many centuries. Some known fluctuations of climate have been irregular, but others recur with some regularity. The best known of these meteorological periodicities are the 11-year sunspot cycle, best shown in the tropics, and the Brückner cycle, of about 35 years, in temperate regions. In the geological past there have been far more extensive changes (see *e.g.*, CLIMATIC HISTORY).

BIBLIOGRAPHY.—Scientific climatology is based upon numerical results, obtained by systematic, long continued, accurate meteorological observations. The essential part of its literature is therefore found in the collection of data published by the various meteorological services. The only comprehensive text-book of climatology is the *Handbuch der Klimatologie* of the late J. von Hann (Stuttgart, 1908–11). The first volume deals with general climatology, and has been translated into English (London and New York, 1903). Reference should be made to this book for further details than are here given. The second and third volumes are devoted to the climates of the different countries of the world. Köppen's *Die Klimate der Erde* and Kendrew's *Climates of the Continents* are valuable reference books. The standard meteorological journal of the world, the *Meteorologische Zeitschrift* (Braunschweig, monthly), is indispensable. The *Quarterly Journal of the Royal Meteorological Society* (London), the *Meteorological Magazine* (London), and the *Monthly Weather Review* (Washington, D. C.) are also valuable. The best collection of charts is that in the *Atlas of Meteorology* (London, 1899) which gives an excellent working bibliography. *See* also the bibliography issued by the Royal Meteorological Society.

CLIMATE IN THE TREATMENT OF DISEASE.

Broadly speaking, purity of air (*i.e.*, freedom from solid particles and irritating gases), average temperature, range of temperature, amounts of sunshine and of humidity are the most important considerations in the climatic treatment of disease. Social and economic conditions in any given locality are important but are not discussed here. Individuals react both to heat and cold very differently. At health resorts, where the temperature varies between 55° and 70° F., strong individuals gradually lose strength, whereas a delicate person gains vigour of mind and body and puts on weight. And a corresponding intensity of cold acts in the reverse manner in each case. Thus a moderately warm health resort suits delicate, convalescent or elderly people. Cold, however, when combined with wind and damp, must be avoided by the aged, the delicate, and those prone to gouty and rheumatic affections. The moisture of the atmosphere controls the distribution of warmth on the earth, and is closely bound up with the prevailing winds, temperature, light and pressure. In dry air the evaporation from skin and lungs is increased, especially if the sunshine be plentiful and the altitude high. In warm moist air strength is lost and digestive troubles are common. In moist cold air perspiration is checked, and rheumatic and joint affections are common. The main differences between mountain air and that of the plains depend on the former being more rarefied, colder, of a lower absolute humidity, and offering less resistance to the sun's rays. As the altitude is raised, circulation and respiration are quickened, probably as an effort on the part of the organism to compensate for the diminished supply of oxygen, and somewhat more gradually body weight and the number of red blood corpuscles increase, this increase persisting after a return to lower ground. Thus children and young people are especially likely to benefit by the impetus given to growth and the blood-forming organs. For older people, however, the benefit depends on whether their organs of circulation and respiration can respond to the increased demands on them. For anaemia, pulmonary tuberculosis, deficient expansion of the lungs, neurasthenia, and the debility following fevers and malaria, mountain air is invaluable. But where there is valvular disease of the heart, or rapidly advancing disease of the lungs, it is to be avoided. Light, especially direct sunlight, is of primary importance, the lack of it tending to depression and dyspeptic troubles. Indeed, the modern view is that the value of a climate is determined chiefly by the average intensity of ultra-violet light. Probably its germicidal power accounts in part for the aseptic character of the air of the Alps, the desert and other places.



A "good" climate is that in which all the organs and tissues of the body are kept evenly at work in alternation with rest. Thus a climate with constant moderate variations in its principal factors is the best for the maintenance of health. But the best climate for an invalid depends on the particular weakness from which he suffers. Thus in pulmonary tuberculosis a cool sunny climate is greatly superior to a tropical one. Exposure to strong winds is harmful, since it increases cough. A high altitude, from the sunshine, the purity and stimulating properties of the air, is of value

INSTRUMENTS FOR DETERMINING CONDITIONS OF THE WEATHER

1. Mercurial barometer, invented by Torricelli in 1643. Each tube holds a column of mercury, which rises and falls according to pressure of surrounding air. 2. Anemometer, for measuring velocity of wind. Three cups attached to horizontal arms revolve at speed varying according to wind velocity. 3. Windvane or anemoscope, indicates direction of the wind. This 4-ft. vane may be connected with the recording instrument (fig. 4). 4. Weather recording register equipped to record changes at one-minute intervals. Instrument registers the velocity and direction of wind, rainfall in hundredths inches and the duration of sunshine. 5. Tipping bucket rain gauge, in parts. 6. Standard barograph or recording aneroid barometer, with cover removed. 7. Intermediate range thermograph which traces a continuous record of the temperature on a revolving drum. 8. Thermal sunshine recorder, electrically connected with recording instrument (fig. 4), determines duration of sunshine

BY COURTESY OF THE U.S. WEATHER BUREAU

LAUNCHING A RADIOSONDE, ROBOT WEATHER OBSERVER

A sounding balloon carries the radiosonde to heights of 10 to 15 mi. During the flight the instrument emits, at brief intervals, radio signals which are recorded by the station's ground equipment. By referring these recorded signals to a calibration chart the pressure, temperature and humidity of the atmosphere through which the instrument has been carried are obtained. An attached parachute retards the fall of the radiosonde to the ground after the balloon has burst

to many mild or very early cases, but where the disease is extensive or the heart is irritable, or there is insomnia, high altitudes are contra-indicated. Where the disease is of long standing, with much expectoration, or accompanied by albuminuria, the patient appears to do best in a humid atmosphere but little above the sea level. The climate of Egypt is suitable for cases complicated with bronchitis or bronchiectasis, but is contra-indicated where there is attendant diarrhoea. Madeira and the Canaries are useful when emphysema is present. Bronchitis in young people is best treated by high altitudes, but in older patients by a moist mild climate, except where much expectoration is present.

Delicate children benefit by residence at the seaside and if very delicate, with small power of reaction, the winter should be passed at some mild coast resort. Gouty and rheumatic affections require a dry soil and warm dry climate, cold and moist winds being especially injurious.

For heart affections high altitudes are to be avoided, though some physicians make an exception of mitral cases where the compensation is good. Moderate elevations of 500 to 1,500ft. are preferable to the sea level.

In diseases of the kidneys, a warm dry climate, by stimulating the action of the skin, lessens the work to be done by these organs, and thus is the most beneficial. Extremes of heat and cold and elevated regions are all to be avoided. (*See* HELIOTHERAPY.)

CLIMATIC HISTORY. The geological history of the earth is divided into five main divisions, Archaean or Pre-Cambrian, Palaeozoic, Mesozoic, Tertiary and Quaternary periods (*see* GEOLOGY). These different periods contain evidence of many great changes of climate, but this article is limited to those which have occurred since the appearance of man. The earliest forms of man-like creatures probably appeared towards the close of the Tertiary period, and their development has been greatly influenced by a series of climatic changes which occurred during the Quaternary. The Tertiary is divided into Eocene, Oligocene, Miocene and Pliocene; a fifth stage, the Pleistocene, is now generally included with the Quaternary. The Eocene began 60 million years ago, the Pliocene ended probably 600,000 to a million years ago. At the beginning of the Eocene the climate of middle latitudes was somewhat warmer than it is at present, and in the later Eocene and Oligocene it became very much warmer. Beds of fossil plants of warm temperate aspect dating from these periods have been found north of the Arctic Circle in many regions. In the Miocene the climate was somewhat cooler than in the Oligocene, though probably warmer than the present. At the beginning of Pliocene times, ten to 15 million years ago, the climate of the north temperate regions again became warmer, but this was temporary, and towards the close of this period there was a rapid cooling. This change is well shown in East Anglia, where the earlier Pliocene beds contain mainly southern mollusca, while in the upper part of the Red Crag northern species become increasingly frequent. The later Pliocene beds of East Anglia, the Chillesford beds and Weybourne Crag, contain large numbers of arctic species, and are probably contemporaneous with the first glaciations of Scandinavia and the Alps. The latest bed in this country which was formerly attributed to the Pliocene, the Cromer Forest bed, indicates a return of somewhat warmer conditions; it is succeeded by boulder clays and other deposits of land ice, indicating the oncoming of glacial conditions in England itself. The discovery of Palaeolithic implements in this bed indicates, however, that the forest bed and the underlying Weybourne crag should be removed to the Pleistocene. The "Quaternary" Ice age began on the continent of Europe and in North America in the Pliocene, but it is convenient to ignore this somewhat arbitrary division and to consider the Ice Age as a whole.

The Quaternary Ice Age.—The Quaternary or Pleistocene Ice Age was characterized by the advance of great glaciers or ice-sheets from a number of centres, of which the most important were Scandinavia and the Alps in Europe, the Cordilleras and various other centres in North America. Minor centres of glaciation were located in Spitsbergen, Iceland, Ireland, Scotland and northern England, the Pyrenees, the Caucasus Range, the Himalayas, the mountain ranges of central Asia, Alaska and the whole chain of the Rockies and Andes, the highest mountains of equatorial Africa, south-eastern Australia and New Zealand. The ice-sheets of Greenland and Antarctica are remnants of the Quaternary glaciation, and illustrate the character of the great inland ice-sheets of northern Europe and North America.

Glaciation of the Alps.—The classical work of A. Penck and E. Brückner in the Alpine region has shown that there were four main advances of the glaciers in Central Europe, which they designated Gunz, Mindel, Riss and Wurm. The intervening periods during which the ice retreated (interglacial periods) are termed Gunz-Mindel, Mindel-Riss and Riss-Wurm. In the Gunz glaciation the snow-line probably lay 3,900ft. lower than now, but the remains of this glaciation have been almost entirely obliterated by the later advances. Of the Gunz-Mindel interglacial nothing is known with certainty, but from the amount of erosion performed by the rivers its duration is estimated as 60,000 years. The Mindel glaciation was regarded by Penck and Brückner as the greatest advance of the ice over the eastern half of the Alpine region. The snow-line lay about 4,250ft. below the present. The Mindel-Riss interglacial was very long (about 240,000 years), and for part of the time warmer than the present. The Riss was regarded as the greatest glaciation in the south-west and west, with a snow-line about 4,250ft. below the present. The Riss-Wurm interglacial was relatively short (about 60,000 years), but probably for a time warmer than the present. The Wurm glaciation was considered by Penck and Brückner to have been smaller in extent than the Riss (depression of snow-line 3,900ft.), but the latest worker, W. Soergel, regards it as the greatest glaciation of the Alps. The Wurm was double, the two maxima being separated by a slight retreat. The final retreat of the ice was interrupted by three re-advances, the Bühl, Gschnitz and Daun stages. The interval between the second maximum of the Wurm (Wurm II.) and the Bühl, which is important archaeologically, is termed the Achen oscillation. Penck and Brückner estimated the length of the post-Wurm period as 20,000 years.

Changes of Sea Level.—The changes of sea level during the Quaternary are best known from the work of E. Dépéret in the Mediterranean. He recognizes four shore-lines or raised beaches, representing periods when the sea was considerably above its present level. These were separated by periods of land elevation when the sea was below its present level and the Mediterranean was divided into two separate basins.

TABLE I. *The Divisions of the Quaternary Ice Age* (*the latest are at the top*).

Changes of level.		Glacial stages.	Human Industries.
Monastirian	Upper: Elevation Lower: Submergence to 60ft.	Bühl Re-advance Achen Retreat Wurm Glaciation Riss-Wurm	Magdalenian Solutrean Aurignacian Mousterian Acheulean Evolved Chellean
Tyrrhenian	Upper: Elevation Lower: Submergence to 100ft.	Riss Glaciation Mindel-Riss	Chellean
Milazzian	Upper: Elevation Lower: Submergence to 190ft.	Mindel Glaciation Gunz-Mindel	Pre-Chellean
Sicilian	Upper: Elevation Lower: Submergence to 330ft.	Gunz Glaciation	

Glaciation in Northern Europe.—The history of the Scandinavian ice-sheet is not known so fully as that of the Alps. The ice probably formed first on the Norwegian mountains, but the centre soon shifted to Sweden and the Gulf of Bothnia. The ice-sheet extended into Russia, Germany, Denmark and Holland, and at its maximum filled the North Sea and encroached on the east coast of England, especially over East Anglia, where for a time it united with the ice from northern England. The edge of the

ice-sheet over Europe underwent great fluctuations; it is not known with certainty whether it ever completely melted during the whole course of the Quaternary glaciation, but it is highly probable that this happened during at least the Mindel-Riss interglacial. In East Anglia the Scandinavian ice was followed by English ice bearing great quantities of chalk, which formed the Great Chalky Boulder Clay, but the time relations of the various glacial deposits are not yet settled. Gerard de Geer's study of the deposits left by the retreating ice in Sweden has shown that the last ice-sheet began its final retreat about 20,000 years ago. As in the Alps, the retreat of the ice was interrupted by several re-advances, indicated by great terminal moraines (*see* below).

North America.—In North America great ice-sheets reached lower latitudes than anywhere else on the earth. The ice spread out from three main centres, the Cordilleras in the west, the Keewatin west of Hudson's Bay, and Labrador in the east. The deposits of these various centres are complex, but a succession of five glacial and four interglacial stages has been made out in the Mississippi Valley. The latest glaciation, termed the Wisconsin, was double, like the Wurm, and de Geer has succeeded in correlating the stages of its final retreat with those of the last Scandinavian ice-sheet, but the relations of the earlier glacial stages with those in Europe are uncertain. Interglacial beds in Toronto indicate a long period of retreat and perhaps of complete disappearance of the ice, but their position in the Mississippi sequence is uncertain. In most other parts of the world the glaciation has been shown to include three or four advances of the ice, indicating a general similarity with the sequence in the Alps, but direct correlation is not yet possible.

Stages of Human Culture.—The Quaternary Ice Age roughly coincides with the Palaeolithic (*see* ARCHAEOLOGY: *Old World*) stage of human culture. The industries into which the Palaeolithic of western Europe is divided are shown in table 1 with their probable positions in the glacial sequence, but there is still doubt as to the early Palaeolithic. The Magdalenian falls in the period of arctic climate about the Bühl re-advance, while the Solutrean and Aurignacian occupy the Achen oscillation, a period of dry steppe-like climate which followed Wurm II. The whole Wurm glaciation (Upper Monastirian) is occupied by the Mousterian, which extends back into the Riss-Wurm interglacial (Lower Monastirian), but how far is not quite settled. The controversy has been concerned chiefly with the position of the Chellean industry, which some assign to the Riss-Wurm, others to the Mindel-Riss interglacial. The correlation in table 1 is a compromise, due to Prof. W. J. Sollas, who places the Chellean proper in the Mindel-Riss (Lower Tyrrhenian) and a later development of it, the "evolved Chellean," in the early part of the Riss-Wurm, while the Acheulean occupies the central and latter parts of that interglacial and the Lower Mousterian its closing stages. The fore-runners of the Chellean types (Pre-Chellean) apparently belong to the Gunz-Mindel interglacial (Lower Milazzian).

Late-Glacial and Post-Glacial Periods.—The climatic history of the concluding stages of the Ice Age is best known from Scandinavia, and thanks to the researches of G. de Geer the various stages have been dated. About 20,000 B.C. the ice-edge lay for a time across Denmark and the Baltic coast of Germany and formed the *Daniglacial* moraine. After a period of retreat, the ice-edge halted again near the coast of the Scandinavian peninsula, where it formed the *Gotiglacial* moraine. The ice then vacated Scania, but there was another long halt about 9000 B.C., forming the great *Fennoscandian* moraines. Up to this time the recession had been comparatively slow, and the edge of the ice had changed but little on the coast of Norway and in northern Finland, while it had everywhere been bordered by a belt of Arctic plants, showing that the temperature was still very low. After the formation of the Fennoscandian moraines, however, there followed a period of very rapid retreat, termed *Finiglacial* time, during which temperate plants occupied almost immediately the ground vacated by the ice, indicating a comparatively high temperature. By about 7000 B.C. the remnants of the ice-sheet had shrunk to a long narrow strip along the centre of Scandinavia. After a short halt termed the *Ragunda* Pause, the ice-sheet split into two separate portions about 6500 B.C., and this date is regarded by Scandinavian geologists as the "official" end of the Ice Age. The correlation between the stages of retreat in Scandinavia and the Alps is not yet known, but it is not unlikely that the great Fennoscandian moraines represent the Bühl stage.

In Britain various Arctic plant beds are known which were presumably formed during the halts represented by the Gotiglacial and Fennoscandian moraines, and there were local re-advances of mountain glaciers in Scotland at the same times. The retreat stages of other centres of glaciation are not yet known in detail, but de Geer and Ernst Antevs have been able to date parts of the retreat stages of the ice-sheets in Canada and southern Argentina by comparing the relative thicknesses of successive annual clay deposits with those in Sweden.

Changes in Land and Sea Distribution.—As the Scandinavian ice-sheet began to vacate the Baltic basin, the latter was occupied by a fresh-water lake, bounded on the north by the ice. After the formation of the Fennoscandian moraines a subsidence of the land allowed the ingress of the sea, both from the Atlantic across Scania and from the White sea across Finland. The site of the Baltic was now occupied by the Arctic sea, called the *Yoldia sea* from the presence of the high northern mollusc *Yoldia arctica*. About the time of the Ragunda Pause the land rose again and both outlets to the ocean were closed. The Baltic now became a fresh-water lake, which from its characteristic mollusc is termed the *Ancylus* lake. The greater part of the Ancylus lake stage falls in post-glacial time, during which the last remnants of the ice-sheet disappeared. About 4000 B.C. a new period of submergence began in the south-west Baltic, again admitting the waters of the Atlantic and forming the *Littorina sea*. This sea was warmer and more saline than the present Baltic, because the inlet from the Atlantic was wider and deeper. The maximum subsidence probably occurred about 3000 B.C., after which the land gradually rose again and conditions approached those of the present.

A raised beach at a height of about ten ft. above the present beach is found almost all over the world, and in many parts is accompanied by a kind of fauna now known only from lower latitudes. Such a widespread change of level indicates a rise of the sea, due to a greater volume of water in the oceans. The additional water can only have come from a melting back of the still existing ice-sheets, especially of Greenland and Antarctica, beyond their present limits; there is also independent evidence that this occurred. This general warm period is termed the *Climatic Optimum*; it falls somewhere within the time of the Littorina sea and probably between 2000 and 1000 B.C.

Vegetation.—Much information as to late-glacial and post-glacial climates is provided by the vegetation, especially of peat-bogs. In central Europe the Wurm glaciation was accompanied and followed by tundra, which gave place during the latter half of the Achen oscillation to dry cold steppe conditions during which Solutrean man, who hunted the horse, penetrated Europe from the east. In the Lower Magdalenian, the culture of which is based on the reindeer, conditions again became moister and colder, and the tundra returned for a short time, to be rapidly replaced by pine forest spreading up from the south-east. In the Upper Magdalenian the pine began to be replaced by dense forests of oak and the reindeer gave way to the red deer. Dense forests were almost impenetrable to primitive man, and in central Europe there is almost a gap—the "hiatus"—between Palaeolithic and neolithic industries.

In Scandinavia the retreating ice-sheet was bordered by a broad zone of Arctic vegetation until the close of the Fennoscandian halt. The aspen appeared in the much warmer Finiglacial, the fir in the Ancylus period. The very favourable conditions of Littorina time were marked by a wealth of new trees, including oak, hazel and beech; at one time the hazel greatly exceeded its present limits both of latitude and height.

Wet and Dry Periods.—The post-glacial period has had marked alternations of wet and dry climates, which were first set out by the Norwegian Axel Blytt. The time of the Ancylus lake was generally dry, with warm summers but cold winters; Blytt termed this the *Boreal* stage. The early part of Littorina time

was moist, with very mild winters and summers probably as warm as at present, forming the *Atlantic* stage, which was marked by a great growth of peat in northern and western Europe. About 3000 B.C. the warm moist conditions gave way to a dry climate, with very warm summers and winters no colder than the present. The surfaces of the peat-bogs dried up, and in Scandinavia, Scotland and Ireland they were occupied by oak forests; in Germany there is instead a layer of dry heath peat. Blytt terms this the *Sub-Boreal* period. About 850 B.C. there was a marked deterioration of climate, which became moist and cold, forming the *Sub-Atlantic* period, when the forests on the peat-bogs died and were replaced by a new and very rapid growth of peat. The change from the very favourable climate of the Sub-Boreal to the unfavourable climate of the Sub-Atlantic was very marked in the Alps; during the Bronze Age and the beginning of the Early Iron Age the climate was highly favourable and there was free communication across the passes; but early in the Iron Age the passes were closed and human occupation was banished to the lowest and warmest valleys, while at the same time many of the lake-dwellings were submerged. It seems probable that the Daun re-advance of the Alpine glaciers should be attributed to this stage; Penck and Brückner dated the Daun re-advance as older than the Bronze Age, but on very scanty evidence.

The Boreal period is not well shown in the British Isles, but the succession of Atlantic peat, Sub-Boreal forest and Sub-Atlantic peat is well seen in Ireland, most of Scotland and western England but not well developed in eastern England.

Summary.—The various late-glacial and post-glacial stages in Scandinavia may be summarized as follows:

TABLE 2. *Late-glacial and Post-glacial Stages.*

Date B.C.	Scandinavian Ice Sheet.	Land and Sea.	Trees.	Wet and dry periods.
0	Post-glacial	Littorina Sea	Oak Beech Hazel	Sub-Atlantic
1000				
2000				Sub-Boreal
3000				
4000				Atlantic
5000		Ancylus Lake	Fir	
6000				Boreal
7000	Ragunda Pause		Aspen	
8000	Finiglacial Retreat	Yoldia Sea	Arctic Plants	Sub-Arctic and Arctic
9000	Fennoscandian Halt	Ice-Lakes		
10000				

THE HISTORICAL PERIOD

There is no clear boundary between the geological and historical periods, for in Egypt and south-west Asia the beginnings of history are almost contemporary with the end of the Ice Age in Scandinavia. In the arid regions of Arabia, Mesopotamia and central Asia variations of rainfall are of much greater importance than small variations of temperature, and this discussion is accordingly limited to the alternations of wet and dry periods.

Persia.—The semi-arid settlement of Anau on the northern margin of Persia is important. This site was occupied from time to time and abandoned during the intervening periods, and since there is no evidence of conquest, while the periods of abandonment are represented by desert formations, it is highly probable that the interruptions were due to drought. These settlements were investigated by Mr. Raphael Pumpelly, who dated them by means of the relative thickness of deposits. According to Pumpelly's estimates the first settlement began about 9000 B.C., the second, which immediately succeeded it, about 6000 B.C. The last part of the first settlement and the whole of the second show evidence of gradually increasing drought, and the site was abandoned soon after 6000 B.C. It was reoccupied, after an interval of desert conditions, about 5200 B.C. The third settlement continued until about 2200 B.C., with a short interruption, probably due to drought, about 3000 B.C. These estimates of the age of Anau appear to be far too great, and H. Peake and H. J. Fleure suggest that the first settlement did not begin till about 3900 B.C., while the third settlement lasted from about 2500 to 1600 B.C. At the close of the third period there began a period of intense drought, and Anau was not reoccupied until the Iron Age, probably about 750 B.C.

It is highly probable that in semi-arid regions the amount of unrest and migration increases during periods of drought, so that we can infer the variations of dryness from the frequencies of migrations. A period of extensive migration began about 2650 B.C. and culminated between 2300 and 2050. Another maximum occurred about 1350 to 1300, after which the desert peoples began to settle down, and remained quiet until the Arabian dispersal of the seventh century A.D. (which began before the birth of Mohammed).

Caspian Sea.—During the Christian era our information is mainly derived from the variations of level of the Caspian Sea, amplified and supported by records of other lakes in Asia, and by Chinese archives. There is some doubtful evidence that the level of the Caspian was high about A.D. 0, but this is not confirmed by other sources. In the 5th century A.D. the Caspian was very low. Then follows a period of rapid fluctuations; high level about 920, low about 1125, very high from 1306 to 1325 and again early in the 15th century and about 1560 to 1640.

Africa.—The evidence from northern Africa is mainly provided by the levels of the Nile floods, the history of Kharga Oasis, and the variations in the level of civilization in the Sahara. These point to a rainfall much higher than the present about 500 B.C., a minimum about A.D. 200, a slight improvement about 400, a very dry season from 700 to 1000, and a great improvement from about 1225 to 1300, followed by a decline to present conditions. It is interesting that E. J. Wayland has recently shown the existence of a marked dry period in central Africa in Neolithic times, probably representing the Sub-Boreal period.

America.—In North America the evidence is derived mainly from the width of the annual rings of growth of the "Big Trees" of California; the curve of tree growth can be checked and adjusted by the variations in the levels of the salt lakes of western America, and by archaeological evidence. The result shows that a long dry period ended about 1000 to 800 B.C., followed by a period of high rainfall from 700 B.C. to A.D. 200, reaching a strongly marked maximum at 400 B.C. A long dry period began about A.D. 400 and continued until about 1250, with one break at about 1000, and there was a further dry spell in the 15th century.

In Yucatan and central America the Mayan civilization reached its highest level apparently from 100 B.C. to A.D. 350. After about 350 came the Mayan "Dark Ages," when southern Yucatan relapsed into barbarism. A revival occurred about A.D. 1000, but did not reach the level of the earlier period and probably lasted little more than two centuries. The ruins are now overgrown by dense forests, and Ellsworth Huntington makes the plausible assumption that the periods of high culture represent dry periods. If so, these are contemporaneous with the wet periods of Arizona, and represent a southward swing of all the climatic belts.

Recent excavations in southern Greenland have shown that its climate was far more favourable in the tenth century than it is to-day, and Baffin Bay seems to have been almost free of ice. There was a deterioration about A.D. 1000, followed by a slight improvement during the 11th and 12th centuries, after which the climate rapidly became very bad. The ground, which at first thawed to a considerable depth every summer, became permanently frozen about A.D. 1400.

CLIMAX, JOHN (*c.* 525–600 A.D.), ascetic and mystic, also called Scholasticus and Sinaïtes. After 40 years in a cave at the foot of Mount Sinai, he became abbot of the monastery. His life has been written by Daniel, a monk of the monastery of Raithu on the Red sea. He derives his name Climax (or Climacus) from his work of the same name (Κλῖμαξ τοῦ Παραδείσου, "Ladder to Paradise"), in 30 sections, corresponding to the 30 years of the life of Christ. It is written in a simple and popular style, and treats of the vices that hinder the attainment of holiness and the Christian virtues.

BIBLIOGRAPHY.—Migne, *Patr. graeca*, lxxxviii (including the biography by Daniel); *see* also C. Krumbacher, *Geschichte der byzantinischen Litteratur* (1897); Herzog-Hauck, *Realencyklopädie*. The *Ladder* has been translated into several languages—into English by Father Robert, Mount St. Bernard's abbey, Leicestershire (1856).

CLIMB INDICATOR: *see* ALTIMETRY.

CLIMBING BITTERSWEET (*Celastrus scandens*), a North American climbing shrub of the staff-tree family (Celastraceae), called also false bittersweet and waxwork. It grows, mostly in rich soil, from Quebec to Manitoba and southward to North Carolina and New Mexico, usually trailing on banks or small shrubs but sometimes climbing to a height of 25 ft. on trees. It has smooth, pointed leaves and small greenish flowers and matures in autumn showy clusters of orange-yellow, berrylike capsules, which split open after frost, disclosing the crimson coverings (arils) enclosing the seeds. The handsome, persistent fruit is used in winter for indoor decoration. (*See* BITTERSWEET.)

CLIMBING FERN, the botanical genus *Lygodium*, with 40 species, chiefly in the warmer parts of the old world. The plants have a creeping stem, on the upper face of which is borne a row of leaves. Each leaf has a slender, stemlike axis, which twines round a support and bears leaflets at intervals; it goes on growing indefinitely. Several species are favourite greenhouse plants. The American climbing fern (*L. palmatum*), called also Hartford fern and Windsor fern, one of the most beautiful ferns native to the United States, grows in open woods from New Hampshire to Pennsylvania and Ohio south to Florida and Tennessee.

CLIM (OR CLYM) **OF THE CLOUGH,** a legendary English archer, a supposed companion of the Robin Hood band. He is commemorated in the ballad "Adam Bell, Clym of the Cloughe and Wyllyam of Cloudeslee." The three were outlaws who had many adventures of the Robin Hood type. The oldest printed copy of this ballad is dated 1550.

CLINCHANT, JUSTIN (1820–1881), French soldier, was born at Thiaucourt (Meurthe) on Dec. 24, 1820, and died in Paris on March 20, 1881. He entered the army from St. Cyr in 1841. He served in Algeria (1847–52), in the Crimea (1854–55) and in Mexico. He held a brigade command in 1870, was captured at Metz but escaped and was placed in command of the 20th corps of the army of the east. He was under Gen. Charles Bourbaki during the campaign of the Jura; and when Bourbaki attempted to commit suicide, he succeeded to the command (Jan. 23, 1871), only to be driven with 84,000 men over the Swiss frontier at Pontarlier. In 1871 Clinchant commanded the 5th corps operating against the commune. He was military governor of Paris when he died.

CLINIC, an organized medical service offering diagnostic, therapeutic or preventive treatment to ambulatory patients. The word originally meant a bedside lecture about a sick patient before a group of physicians or medical students. In medical education clinic is still so used but may also mean a particular lecture, classroom or outpatient examination where several medical men discuss their views. Often in Europe and occasionally in America the term covers an entire teaching centre, including the hospital and the ambulatory facilities. The usual meaning, however, has come to include any organized medical service to ambulatory patients. Such service may or may not be connected with a hospital. In addition, clinic is used to designate the entire activities of a general clinic or may be used to designate only a particular division of the work; *e.g.*, the neurology clinic, the surgery clinic, etc.

The first clinic in the English-speaking world, the London dispensary, was founded in 1696 as a central means of dispensing medicines to the sick poor whom the physicians were treating in the patients' homes. The New York, Philadelphia and Boston dispensaries, founded in 1771, 1786 and 1796, respectively, had the same object in view. Later, for the sake of convenience, physicians began to treat their free patients at the dispensary. The number of such clinics did not increase rapidly and as late as 1890 only 132 were operating in the United States. The impetus for the mushroomlike growth that occurred after that time came from the hospitals and from the public-health movement.

During the latter part of the 1800s the modern hospital as a complex of skilled technical personnel and extensive diagnostic equipment began to take shape. During this period some of the hospitals connected with medical schools inaugurated outpatient departments for teaching as well as for charitable purposes. Johns Hopkins and Massachusetts General hospitals are believed to be the American pioneers in this form of medical education. The advantages of ambulatory care in close proximity to the facilities of a hospital became apparent and such hospital clinics multiplied rapidly. In 1945 about 2,623 hospitals in the United States had organized clinic services. The number of different patients treated reached 4,420,406 and the visits totalled 30,784,890.

A hospital clinic in general follows the same pattern of medical departmentation as the hospital developed for its inpatient work. For this reason hospital clinics are mostly concerned with acute diseases. The physicians in the clinics are usually the same physicians who treat bed patients in the hospital. Many hospitals operating charity clinics require the recent appointees to the medical staff to serve a period in the clinics as a step to senior staff membership. Such physicians ordinarily work no more than one half-day each week in the clinics and usually receive no compensation for this part-time work. In most hospital clinics care is made available only to the medically indigent and no professional fee is charged. Practically all such clinics, however, charge a small registration fee to help cover operating costs if the patient is able to make such a payment. A number of successful attempts have been made to extend hospital clinic care to pay patients. Most of this effort was in the area of the lower-income groups although in a few hospitals no income restrictions were imposed for admission to clinic care.

The public-health movements, mainly concerned with preventive medicine, child and maternal welfare and other medical problems affecting broad segments of the population, contributed to the establishment of more than 6,000 public health clinics in the United States after 1900. Unlike the hospital clinics, which had their greatest growth in the metropolitan areas, the public-health clinics are located in large numbers in the smaller towns and villages as well as in the cities. Because so many of the clinics are located outside of congested population areas the total number of annual visits, despite the large number of clinics, probably does not exceed 15,000,000. The first great movement in this field resulted in the founding of the National Association for the Study and Prevention of Tuberculosis in 1904. It was the association's goal to study and prevent tuberculosis by making clinic facilities available in every city and county for free examination and treatment. Ten years later about 500 clinics were established. Other associations in related fields quickly adopted this method to improve the quality and extend the quantity of their medical service. Such clinics are usually concerned with one particular medical condition and fall mainly into the following categories: tuberculosis, tumour, venereal disease, prenatal, well-baby, dental, tonsil, eye, crippled children and mental hygiene. A later development was the travelling clinics such as dental clinics for school children and tuberculosis case-finding clinics in industrial plants. Usually no charge is made for service in public-health clinics and for many medical conditions no income restrictions are imposed. A few are operated in connection with hospitals but most such clinics use public buildings or space furnished by welfare and other social agencies. Financial support is mostly from the same sources. Doctors serving in the clinics are recompensed for the time spent or are on a full-salary basis.

The advantages of group medical service, with facilities and technical personnel beyond the means of an individual practitioner and the added benefits of group consultation, encouraged the estab-

lishment of an increasing number of pay or private clinics. This type of clinic is essentially a voluntary association of physicians engaged in the practice of medicine on a group basis. Common facilities are used and the resulting expense and income is shared by a predetermined division. Several of these have achieved a national reputation and attract patients from a wide area. It was estimated that more than 500 such private clinics were operating in the United States in 1947. The majority of these were general clinics; *i.e.*, they had several of the different medical specialties represented in their group; but a sizeable number limited their work to one medical specialty. Usually, the group is independent of any hospital or other agency, but some clinics own and operate their own hospital facilities. In other instances the clinic is a part of a prepaid health-service plan. (R. E. Bn.)

CLINICAL PSYCHOLOGY: *see* Psychology.

CLINKER, in industry, the common name for coal residues which are formed in lumps, partly fused, in grates or furnaces. Such clinker is used for many purposes as a raw material, and is a useful matrix for inferior portland cement concrete. The name is also applied to the fused masses of brick which occur in brick ovens. What is really a different word, but with the same spelling, is derived from *clinch*, or *clench*, a common Teutonic word, meaning to "fasten together." This word appears in the form "clinker-built" as distinguished from "carvel-built" for a boat whose strakes overlap and are not fastened "flush."

CLINOGRAPH, a set square, the acute angles of which are made adjustable by connecting the side opposite the right angle to one of the other sides by a hinge; it is frequently employed in mechanical drawing (*see* Drawing, Engineering).

CLINTON, DE WITT (1769–1828), U.S. political leader, was born on March 2, 1769, at Little Britain, N.Y. His father, James Clinton (1736–1812), served as a captain of provincial troops in the French and Indian War, and as a brigadier general in the American army in the Revolutionary War. De Witt Clinton graduated at Columbia college in 1786, and in 1790 was admitted to the bar. From 1790 to 1795 he was the private secretary of his uncle, George Clinton, governor of New York and a leader of the Republican party. He entered the state senate in 1798, serving until 1802. He at once became a dominant factor in New York politics, and for the next quarter of a century he played a leading role in the history of the commonwealth. From 1801 to 1802 and from 1806 to 1807 he was a member of the council of appointment; and realizing the power this body possessed through its influence over the selection of a vast number of state, county and municipal officers, he secured in 1801, while his uncle was governor, the removal of a number of Federalist officeholders, in order to strengthen the Republican organization by new appointments. On this account Clinton has generally been regarded as the originator of the "spoils system" in New York; but he was really opposed to the wholesale proscription of opponents that became such a feature of U.S. politics in later years. It was his plan to fill the more important offices with Republicans, since they had been excluded from appointive office during the Federalist ascendancy, and to divide the smaller places between the parties somewhat in accordance with their relative strength. In counties where the Federalists had a majority very few removals were made.

In 1802 Clinton became a member of the U.S. senate, but resigned in the following year to become mayor of New York city, an office which he held for ten years in the period 1803–15. During his mayoralty he also held other offices, being a member of the state senate in 1806–11 and lieutenant governor in 1811–13. In 1812, after a congressional caucus at Washington, D.C., had nominated James Madison for a second term, the Republicans of New York, desiring to break up the so-called Virginia dynasty as well as the system of congressional nominations, nominated Clinton for the presidency by a legislative caucus. Opponents of a second war with Great Britain had revived the Federalist organization, and Federalists from 11 states met in New York and agreed to support Clinton, not because of his war views, which were not in accord with their own, but as a protest against the policy of Madison. In the election Clinton received 89 electoral votes and Madison 128.

As a member of the legislature Clinton was active in securing the abolition of slavery and of imprisonment for debt, and in perfecting a system of free public schools. In 1810 he was a member of a commission to explore a route for a canal between Lake Erie and the Hudson river, and in 1811 he and Gouverneur Morris were sent to Washington to secure federal aid for the undertaking, but were unsuccessful. The second war with Great Britain prevented any immediate action by the state; but in 1816 Clinton was active in reviving the project, and a new commission was appointed, of which he became president. His connection with this work so enhanced his popularity that he was chosen governor by an overwhelming majority and served for two triennial terms (1817–23). As governor he devoted his energies to the construction of the canal, but the opposition to his administration, led by Martin Van Buren and Tammany Hall, became so formidable by 1822 that he declined to seek a third term. His successful opponents, however, overreached themselves when in 1824 they removed him from the office of canal commissioner. This partisan action aroused such indignation that at the next election he was again chosen governor, by a large majority, and served from 1825 until his death. As governor he took part in the formal ceremony of admitting the waters of Lake Erie into the canal in Oct. 1825, and thus witnessed the completion of a work which owed more to him than to any other man. Clinton died at Albany, N.Y., on Feb. 11, 1828. In addition to his interest in politics and public improvements, he devoted much study to the natural sciences; among his published works are a *Memoir on the Antiquities of Western New York* (1818) and *Letters on the Natural History and Internal Resources of New York* (1822).

McBain, *De Witt Clinton and the Origin of the Spoils System in New York* (1907); T. E. Benedict, "De Witt Clinton's Birthplace," *Olde Ulster*, vol. vii, pp. 65–69 (1911); and E. A. Fitzpatrick, *The Educational Views and Influence of De Witt Clinton* (1911).

CLINTON, GEORGE (1739–1812), American soldier and political leader, was born at Little Britain, Ulster (now Orange) county, N.Y., on July 26, 1739, the son of Charles Clinton (1690–1773), who had emigrated to America in 1729, and commanded a regiment of provincial troops in the French and Indian War. The son went to sea at the age of 16, but, finding the sailor's life distasteful, joined his father's regiment and accompanied him as lieutenant in the expedition against Fort Frontenac in 1758. After the war he practised law and held a number of minor civil offices in Ulster county. From 1768 to 1775 he sat in the New York provincial assembly, and in the controversies with Great Britain zealously championed the colonial cause. In 1774 he was a member of the New York committee of correspondence, and in 1775 was a member of the second Continental Congress. In December of that year he was appointed a brigadier general of militia by the New York provincial congress. In the following summer, being ordered by George Washington to assist in the defense of New York, he left Philadelphia, after voting for the Declaration of Independence, and before he could sign it.

Clinton took part in the battle of White Plains (Oct. 28, 1776), and was charged with the defense of the highlands of the Hudson, where, with De Witt Clinton, in Oct. 1777, he offered a firm but unsuccessful resistance to the advance of Sir Henry Clinton. In March 1777 he had been appointed by congress a brigadier general in the continental army, and he thus held two commissions, since the state convention refused to accept his resignation as brigadier general of militia. So great was Clinton's popularity at this time that at the first election under the new state constitution he was chosen both governor and lieutenant governor. He declined the latter office, and on July 30, 1777, entered upon his duties as governor, which were at first largely of a military nature. In 1780 he took the field and checked the advance of Sir John Johnson and the Indians in the Mohawk valley. In his administration Clinton was energetic and patriotic, and though not so intellectual as some of his New York contemporaries, he was more popular than any of them. He served as governor for 18 successive years (1777–95), and for another triennial term from 1801 to

1804. In the elections of 1780, 1783 and 1786 he had no opponent. In 1800–01 he was a member of the assembly.

In the struggle in New York over the adoption of the federal constitution he was one of the leaders of the opposition, but in the state convention of 1788, over which he presided, his party was defeated and the constitution was ratified. In national politics he was a follower of Thomas Jefferson, and in state politics he led the long-dominant faction known as "Clintonians." In 1789, 1792 and 1796 Clinton received a number of votes in the electoral college but not enough to secure him the vice-presidency, which was then awarded to the recipient of the second highest number of votes. In 1804, however, after the method of voting had been changed, he was nominated for the vice-presidency by a congressional caucus and was duly elected. In 1808 he sought nomination for the presidency and was greatly disappointed when this went to James Madison. He was again chosen as vice-president, however, and died in Washington, D.C., before the expiration of his term, on April 20, 1812. He was buried in the congressional cemetery, from which in May 1908, his remains were transferred to Kingston, N.Y. His casting vote in the senate in 1811 defeated the bill for the renewal of the charter of the Bank of the United States.

The *Public Papers of George Clinton*, 6 vol. (1899–1902) have been published by the state of New York. *See* also St. S. Spaulding, *George Clinton and the New York Democracy* (1926).

CLINTON, SIR HENRY (*c.* 1738–1795), British general, was the son of Adm. George Clinton (governor of Newfoundland and subsequently of New York) and grandson of the 6th earl of Lincoln. After serving in the New York militia, he came to England and joined the Coldstream guards. In 1758 he became captain and lieutenant colonel in the Grenadier guards, and in 1760–62 served as aide-de-camp to Ferdinand of Brunswick in the Seven Years' War. He became major general in 1772. From 1772 to 1784, thanks to the influence of his cousin, the 2nd duke of Newcastle, he had a seat in parliament, first for Boroughbridge and subsequently for Newark, but for the greater part of this time he was on active service in America in the War of Independence. He took part in the battles of Bunker Hill and Long Island, subsequently taking possession of New York. For his share in the battle of Long Island he was made a lieutenant general and K.B. After Saratoga he succeeded Sir William Howe as commander in chief in North America. He had already been made a local general. He at once concentrated the British forces at New York, pursuing a policy of foraying expeditions in place of regular campaigns. In 1779 he invaded South Carolina, and in 1780 in conjunction with Adm. M. Arbuthnot captured Charleston. There was constant friction between him and Lord Cornwallis, his second in command, and in 1782, after the capitulation of Cornwallis at Yorktown, he was superseded by Sir Guy Carleton. Returning to England, he published in 1783 his *Narrative of the Campaign of 1781 in North America*, which provoked an acrimonious reply from Lord Cornwallis. He was elected M.P. for Launceston in 1790, and in 1794 was made governor of Gibraltar, where he died on Dec. 23, 1795.

His younger son, SIR HENRY CLINTON (1771–1829), entered the army in 1787 and saw some service with the Prussians in Holland in 1789. He was almost continuously in active service; in the Corunna campaign of 1808–09, he was adjutant general to his close friend, Sir John Moore. Promoted major general in 1810, he returned to the peninsula to fill a divisional command under the duke of Wellington in 1811. His division played a notable part in the capture of the forts at Salamanca and in the battle of Salamanca (1812), and he was given the local rank of lieutenant general early in 1813. For his conduct at Vittoria he was made a K.B., and he took part in the subsequent victories of the Nive, Orthes and Toulouse. At the end of the war he was made a lieutenant general and inspector general of infantry. Clinton commanded a division with distinction at Waterloo. He died on Dec. 11, 1829.

CLINTON, HENRY FYNES (1781–1852), British classical scholar and chronologist, was born at Gamston in Nottinghamshire. He was educated at Westminster and Oxford, and from 1806 to 1826 was M.P. for Aldborough. The value of his *Fasti*, which set classical chronology on a scientific basis, can scarcely be overestimated, even though subsequent research has corrected some of his conclusions.

His chief works are: *Fasti Hellenici, the Civil and Literary Chronology of Greece from the 55th to the 124th Olympiad* (1824–51), including dissertations on points of Greek history and scriptural chronology; and *Fasti Romani, the Civil and Literary Chronology of Rome and Constantinople from the Death of Augustus to the Death of Heraclius* (1845–50). In 1851 and 1853 respectively he published epitomes of the above. *The Literary Remains of H. F. Clinton* (the first part of which contains an autobiography written in 1818) were edited by C. J. F. Clinton in 1854.

CLINTON, a city of Illinois, U.S., on the Illinois Central railroad, 22 mi. S. of Bloomington; the county seat of De Witt county. Pop. (1950) 5,870; (1940) 6,331 by the federal census. It is in the heart of the corn belt; and has railroad shops and clothing factories. It was settled about 1836, and was incorporated as a city in 1855.

CLINTON, a city of Vermillion county, Indiana, U.S., on the Wabash river, 15 mi. N. of Terre Haute and 8 mi. E. of the Illinois state line. It is 1 mi. from federal highway 41, and is served by the Chicago and Eastern Illinois railway. In 1950 the population was 6,576; in 1940 it was 7,092 and in 1930, 7,936 by federal census. Clinton is in a farming and coal mining region, and has varied manufactures, including mining and agricultural machinery, meat and dairy products, sauces and relishes, vaults and other articles of cement, flour, overalls, furniture, carpenter's tools, children's garments and prefabricated houses. The county hospital is located there. Clinton was incorporated as a city in 1893.

CLINTON, a city in the extreme eastern part of Iowa, U.S., on the Mississippi river where the Lincoln highway crosses it; the county seat of Clinton county. It is on the Burlington; the Chicago and North Western; the Chicago, Milwaukee, St. Paul and Pacific; and the Rock Island, and is served by several bus lines. The population in the 1950 federal census was 30,151 and in 1940 it was 26,270.

The city lies 600 ft. above sea level, and has a background of rolling farm land to the west and rocky bluffs to the north. It has a large system of public parks, mostly along the Mississippi, and beautiful homes shaded by elms which the early settlers planted. Clinton was formerly a great sawmill centre, but when the supply of lumber gave out in the north, the city turned to other industries, such as corn products, mill work, builders' hardware, stock feeds, cellophane, structural steel, and steel and wire specialties. The annual factory output is valued at $30,000,000. There is a 2,000-bed army general hospital in the city. The first settlers arrived in 1835. The town was replatted in 1855 and named after De Witt Clinton, former governor of New York. It was incorporated in 1859 and reincorporated in 1881.

CLINTON, a town of Worcester county, Massachusetts, U.S., on the Nashua river, 15 mi. N.N.E. of Worcester. It is served by the Boston and Maine and the New York, New Haven and Hartford railways (freight only). The population in 1950 was 12,295; 12,440 in 1940; 12,817 in 1930; and 12,979 in 1920 by the federal census. The town contains varied and picturesque hilly country, with charming scenery along the river. In its southwest corner, on the southern branch of the Nashua river, is part of the Wachusett dam and reservoir of the water-supply system of the Boston metropolitan area. There are extensive manufactures.

In 1813 cotton cloth was produced there under the factory system, but the first modern textile mill was established in 1838, for making coach lace. The industrial importance of the town is due largely to Erastus Brigham Bigelow (1814–79), inventor of power looms which revolutionized the manufacture of figured fabrics, and of a loom for weaving wire cloth. In 1843, with his brother Horatio M. Bigelow, he established in Clinton the Lancaster mills for the manufacture of ginghams, and about ten years later, the Bigelow carpet mills. Clinton was settled in 1645, and was separated from Lancaster as an independent town in 1850.

CLINTON, a city of Missouri, U.S., 78 mi. S.E. of Kansas City; county seat of Henry county. It is served by the Frisco and the Missouri-Kansas-Texas railways. Population (1950) 6,069. The city lies at the edge of a rolling prairie, 770 ft. above sea

level. It is the trade centre for an agricultural and stock raising district and has large flour mills. Considerable coal is mined in the county. It produces more than 20,000,000 chicks annually. Clinton was laid out in 1836 and incorporated in 1865.

CLINTON, a village of Oneida county, N.Y., U.S., 9 mi. S.W. of Utica, on Oriskany creek and the New York, Ontario and Western railway. The population in 1950 was 1,619; in 1940, 1,478. There are mineral springs and iron mines in the vicinity, and the village has knitting and paint mills and vegetable canneries. Many business and professional men of Utica make it their home. It is the seat of Hamilton college for men (opened as an academy for Indian boys in 1798 and chartered as a college in 1812), which was founded by Samuel Kirkland (1741–1808), a missionary among the Oneida Indians, and named after Alexander Hamilton. Its cornerstone was laid by Baron von Steuben; and its shade trees were presented by Thomas Jefferson. The village was widely known as an educational centre between 1798 and 1907, more than 40 private schools for both boys and girls having been established there during that period. The village, settled about 1786 by pioneers from New England, was named after George Clinton, and was incorporated in 1843. It was the birthplace and the summer home of Elihu Root (1846–1937).

CLINTONIA, a genus of beautiful herbs of the lily family (Liliaceae), named in honour of De Witt Clinton (1769–1828), governor of the state of New York. There are six species, four North American and two Asian, all stemless perennials, with a few broad leaves rising from a slender rootstock, and lilylike flowers, usually borne in clusters (umbels) at the top of the flower stock (scape). The yellow clintonia (*C. borealis*) is found in woods from Newfoundland to Manitoba and southward to North Carolina and Wisconsin; the white clintonia (*C. umbellulata*) occurs in woods from New York and New Jersey to Tennessee and Georgia; the mountain clintonia (*C. uniflora*), with a single white flower, grows from Montana and California northward to Alaska; the western clintonia (*C. andrewsiana*) is found near the Pacific coast in central California.

CLINTONITE: *see* OTTRELITE.

CLIPPER SHIPS, a class of sailing vessel developed principally by U.S. shipbuilders during the first half of the 19th century. The origin of the word clipper is not definitely known. Some authors think that the expression "going at a clip" might have been responsible for it, while others have traced the word to the poets Percy Bysshe Shelley and Robert Burns. The first large ship of the kind was the "Ann McKim" (494 tons), built in Baltimore, Md., in 1833; but smaller vessels of similar construction were already well known as "Baltimore clippers." The gold rush in California, which gave such impetus to the building of these ships, was responsible for the launching of 160 clipper ships within four years, during the first of which 90,000 passengers were carried, while the discovery of gold in Australia soon after caused 400,000 people to be transported to that country in British-owned clippers. Bell, Hall, Steers, Webb, Collier, McKay and Magoun are some of the U.S. families who built clipper ships, and the Osgood, Marshall, Trask, Woodhouse, Delano, DePuyster and Russell families had among their members many captains of these vessels. The type was abandoned by U.S. builders after 1854, when freight rates dropped, and since the U.S. clippers were built of oak or other expensive hardwoods, it was no longer profitable to construct them. Subsequently, for more than a decade, a modified ship known as the "medium clipper" was developed. Its speed, however, never equalled that of the original, or "extreme clipper," which might make as much as 18 knots. Typically, the extreme clipper was a long, slender vessel, with a sharp, long bow and with the three masts slanting backwards and carrying rectangular sails. In small vessels, these characteristics of narrow beam and great sail-carrying capacity had been developed by U.S. builders before 1812. The invention of the type, however, was not American; it was an adaptation of principles that had been carefully studied by French scientists during the 18th century and accepted by the builders of French war vessels, which were then the fastest afloat. The majority of the clippers were built in New England yards, and their usual run was between ports of the eastern U.S. seaboard and China, Australia or San Francisco. But the career of the famous "Nightingale," from the time of its launching in 1851 until its loss in 1893, shows a variety of voyages to every part of the world. The equally well-known "Witch of the Wave" had a similar record, although shorter by about 20 years.

Besides the Californian and Australian gold rushes and the opium and slave trades, which gave such impetus to the building of clipper ships, one of the most potent motives for speed by water in the early 19th century was furnished by the Chinese tea trade. Inasmuch as this commodity quickly loses its flavour in the hold of a ship, annual prizes were offered by London merchants for the delivery at the earliest possible moment of the first crop of the season. Public excitement ran high, and rivalry among the various ships in the annual race from China was keen. One of these, the "Cutty Sark," built in 1869 covered 363 mi. in a day's travel, the record for tea clippers. By 1872, due to the opening of the Suez Canal in 1870 and the greater improvement in and more extended use of steam-propelled boats, these interesting tea races had virtually passed out of existence. With her hull picturesquely painted in bands of white and black, and dummy portholes in black, with her great number of sails and long, sharp bow the clipper ship of the 19th century was "the ideal of applied art and a sheer delight to the eye"—the possessor of "that peculiarly satisfying beauty which always belongs to the thing absolutely fitted for the purpose it is designed to fill." An excellent account has been compiled by Octavius T. Howe and Frederick C. Matthews, *American Clipper Ships 1833–58* (1926–27).

CLISSON, OLIVIER DE (1336–1407), French soldier, was the son of Olivier de Clisson, who was put to death in 1343 on the suspicion of having wished to give up Nantes to the English. He was brought up in England, where his mother, Jeanne de Belleville, had married her second husband. On his return to Brittany he took arms on the side of John of Montfort (John IV of Brittany), distinguishing himself at the battle of Auray (1364), but following differences with John went over to the side of Blois. In 1370 he joined Bertrand du Guesclin and followed him in all his campaigns against the English. On the death of Du Guesclin, Clisson received the constable's sword (1380). He fought against the Flemings, defeating them at Roosebeke (1382), and later commanded the army in Poitou and Flanders (1389) and made an unsuccessful attempt to invade England. On his return to Paris, in 1392, Pierre de Craon tried to assassinate him at the instigation of John IV. In order to punish the latter Charles VI of France, accompanied by the constable, marched on Brittany, but on this expedition the king was seized with madness. The king's uncles took proceedings against Clisson, so that he had to take refuge in Brittany. He was reconciled with John IV and, after the duke's death, in 1399, became protector of the duchy and guardian of the young princes. He died, extremely wealthy, on April 23, 1407.

See G. J. Tondouze, *Du Guesclin, Clisson, Richemont et la fin de la guerre de cent ans* (Paris, 1942); A. Naudin-Hérot, *Le Connétable de Clisson* (Paris, 1938).

CLISSON, a town of western France, in the department of Loire-Inférieure, 17 mi. S.E. of Nantes, at the confluence of the Sèvre and the Moine, both of which are crossed by old bridges. Pop. (1946) 2,712. The town gave its name to the celebrated family of Clisson, of which the most famous member was Olivier de Clisson. It has the imposing ruins of their stronghold, parts of which date from the 13th century. The town and castle were destroyed in 1792 and 1793 during the Vendean wars, but the town was rebuilt shortly afterward.

CLITHEROE, municipal borough, northeast Lancashire, Eng., 35 mi. N.W. from Manchester, on the London Midland Region railway. Pop. (1951) 12,057. Area 3.7 sq.mi. It is finely situated in the valley of the Ribble, at the foot of Pendle hill, a steep plateaulike mass rising to 1,831 ft.

The Honour of Clitheroe (Clyderhow or Cletherwoode) was first held by Roger de Poictou, almost certainly the builder of the castle. He granted it to Robert de Lacy, and it passed by marriage to Thomas, earl of Lancaster, in 1310. It was part of the duchy of Lancaster till Charles II bestowed it on Gen. George Monk,

from whose family it descended through the house of Montague to that of Buccleuch. The first charter was granted about 1283 to the burgesses by Henry de Lacy, confirming the liberties granted by the first Henry de Lacy. The 1283 charter was confirmed by Edward III, Henry V, Henry VIII and James I. Fairs, on Dec. 7 to 9 and March 24 to 26, are held under a charter of Henry IV. A weekly market has been held on Saturday since William I's days. The church of St. Mary Magdalene, though occupying an ancient site, is modern. The town has a grammar school, founded in 1554, and a technical school. On a height commanding the valley stands the keep and other fragments of the Norman castle, but part of the site is occupied by a modern mansion. A large percentage of the population is engaged in the textile industry. In 1558 the borough was granted two members of parliament, and continued to return them till 1832, when the number was reduced to one. In 1885 the borough was disfranchised and is now represented in the Clitheroe division of Lancashire.

Stonyhurst college, 5 mi. S.W. of Clitheroe, is a college for Roman Catholic students. The nucleus of the buildings is a mansion (17th century) given by Thomas Weld in 1795 to refugee Jesuits from the continent. An observatory is attached to the college.

CLITUMNUS, a river in Umbria, It., rising from an abundant spring by the road between the ancient Spoletium and Trebia, 8 mi. from the former, 4 mi. from the latter. After a short course through the territory of Trebia it joins the Tinia, a tributary of the Tiber. Pliny described and Caligula and Honorius visited the lake, which is still a clear pool surrounded by poplars and weeping willows. The stream was personified as a god, whose ancient temple lay near the spring; close by were other smaller shrines, and it occurs under the name *Sacraria* (the "shrines") as a Roman post station.

The building, generally known as the Tempio di Clitunno, close to the spring, is an ancient Christian chapel, its decorative sculptures being contemporary with those of S. Salvatore at Spoleto (4th century).

CLIVE, CAROLINE (1801–1873), English authoress, was born in London, June 24, 1801; died at Whitfield, Herefordshire, on July 13, 1873. She was the daughter of an M.P., Edmund Meysey-Wigley, and married, in 1840, the Rev. Archer Clive.

She published poems and novels under the initial V and is best known as the author of *Paul Ferroll* (1855) a sensational novel.

CLIVE, CATHERINE (KITTY) (1711–1785), British actress, was born, probably in London, in 1711. Her father, William Raftor, an Irishman of good family but small means, had held a captain's commission in the French army under Louis XIV. About 1728 she began to play at Drury Lane, of which Colley Cibber was then manager. She married George Clive, a barrister and a relative of the 1st Lord Clive, but husband and wife soon separated by mutual consent. In 1731 she definitely established her reputation as a comic actress and singer in Charles Coffey's farce-opera adaptation *The Devil to Pay,* and from this time she was always a popular favourite. She acted little outside Drury Lane, where in 1747 she became one of the original members of David Garrick's company. She took part, however, in some of the oratorios of George Frederick Handel, whose friend she was. In 1769, having been a member of Garrick's company for 22 years, she quit the stage, and lived for 16 years in retirement at a villa at Twickenham, which had been given her some time previously by her friend Horace Walpole. Mrs. Clive had small claim to good looks, but as an actress of broad comedy she was unreservedly praised by Oliver Goldsmith, Samuel Johnson and Garrick.

She had a quick temper, which on various occasions involved her in quarrels, and at times sorely tried the patience of Garrick, but her private life remained above suspicion, and she regularly supported her father and his family. She died at Twickenham on Dec. 6, 1785.

Horace Walpole placed in his garden an urn to her memory, bearing an inscription, of which the last two lines run:

> The comic muse with her retired
> And shed a tear when she expired.

See Percy Fitzgerald, *Life of Mrs. Catherine Clive* (1888); W. R. Chetwood, *General History of the Stage* (1749); Thomas Davies, *Memoirs of the Life of David Garrick* (1784).

CLIVE, ROBERT CLIVE, BARON, OF PLASSEY (1725–1774), the statesman and general who founded the empire of British India, was born on Sept. 29, 1725, at Styche, the family estate, in the parish of Moreton Say, Market Drayton, Shropshire. The Clives, or Clyves, were one of the oldest families in the county of Shropshire, having held the manor of that name in the reign of Henry II. One Clive was Irish chancellor of the exchequer under Henry VIII; another was a member of the long parliament; Robert's father for many years represented Montgomeryshire in parliament.

Young Clive was the despair of his teachers. Sent from school to school, and for only a short time at the Merchant Taylors' school, he neglected his books for perilous adventures. But he could read Horace in later life; and write a vigorous English, which marked all his dispatches and made Lord Chatham declare of one of his speeches in the house of commons that it was the most eloquent he had ever heard. At 18 he was sent out to Madras as a "factor" or "writer" in the civil service of the East India company. For the first two years of his residence he felt keenly the separation from home; he was always breaking through the restraints imposed on young "writers"; and he was rarely out of trouble with his fellows, with one of whom he fought a duel. His one solace was found in the governor's library, where he sought to make up for past carelessness by a systematic course of study. He was just of age when, in 1746, Madras was forced to capitulate to the count of la Bourdonnais during the War of the Austrian Succession. The breach of that capitulation by Gen. Joseph F. Dupleix, then at the head of the French settlements in India, led Clive, with others, to escape from the town to the subordinate Fort St. David, about 20 mi. to the south. There Clive obtained an ensign's commission.

At this time India was ready to become the prize of the first conqueror who combined administrative with military skill. For the 40 years since the death of the emperor Aurangzeb, the power of the great mogul had gradually fallen into the hands of his provincial viceroys, or *subadhars.* The three greatest of these were the nawab of the Deccan, or south and central India, who ruled from Hyderabad; the nawab of Bengal, whose capital was Murshidabad; and the nawab, or wazir, of Oudh. The prize lay between Dupleix, who had the genius of an administrator, or rather intriguer, but was no soldier, and Clive, the first of a century's brilliant succession of those "soldier-politicals" to whom Great Britain owed the conquest and consolidation of India. Clive successively established British ascendancy against French influence in the three great provinces under these nawabs; but his merit lay especially in the ability and foresight with which he secured the richest of the three, Bengal. Clive had hardly been able to commend himself to Maj. Stringer Lawrence, the commander of the British troops in Madras and the Deccan, by his courage and skill in several small engagements, when the peace of Aix-la-Chapelle (1748) forced him to return to his civil duties for a short time. An attack of fever which severely affected his spirits led him to visit Bengal. On his return he found a contest going on between two sets of rival claimants for the position of viceroy of the Deccan and for that of nawab of the Carnatic, the greatest of the subordinate states under the Deccan. Dupleix, who took the part of the pretenders to power in both places, was carrying all before him. The British had been weakened by the withdrawal of a large force under Adm. Edward Boscawen and by the return home, on leave, of Major Lawrence; but that officer had appointed Clive commissary for the supply of the troops with provisions, with the rank of captain. More than one disaster had taken place on a small scale, when Clive drew up a plan for dividing the enemy's forces and offered to carry it out himself. The pretender, Chanda Sahib, had been made nawab of the Carnatic with Dupleix's assistance, while the British had taken up the cause of the more legitimate successor, Mohammed Ali. Chanda Sahib had left Arcot, the capital of the Carnatic, to reduce Trich-

inopoly, then held by a weak English battalion. Clive offered to attack Arcot in order to force Chanda Sahib to raise the siege of Trichinopoly. But Madras and Fort St. David could supply him with only 200 Europeans and 300 sepoys. Of the eight officers who led them, four were civilians like Clive himself and six had never been in action. His force had but three fieldpieces. The circumstance that Clive, at the head of this handful, had been seen marching during a storm of thunder and lightning frightened the enemy into evacuating the fort, which the British at once began to strengthen against a siege. Clive treated the great population of the city with so much consideration that they helped him to make successful sallies against the enemy. As the days passed on, Chanda Sahib sent a large army under his son and his French supporters, who entered Arcot and closely besieged Clive in the citadel (1751). The story of the defense of the citadel and of the repulse of the enemy is told in Thomas Macaulay's essay on Clive. He gives the following account of the siege:

"Raja Sahib proceeded to invest the fort, which seemed quite incapable of sustaining a siege. The walls were ruinous, the ditches dry, the ramparts too narrow to admit the guns, and the battlements too low to protect the soldiers. The little garrison had been greatly reduced by casualties. It now consisted of 120 Europeans and 200 sepoys. Only four officers were left, the stock of provisions was scanty, and the commander who had to conduct the defence under circumstances so discouraging was a young man of five and twenty, who had been bred as a bookkeeper. During fifty days the siege went on, and the young captain maintained the defence with a firmness, vigilance and ability which would have done honour to the oldest marshal in Europe. The breach, however, increased day by day. Under such circumstances, any troops so scantily provided with officers might have been expected to show signs of insubordination; and the danger was peculiarly great in a force composed of men differing widely from each other in extraction, colour, language, manners, and religion. But the devotion of the little band to its chief surpassed anything that is related of the Tenth Legion of Caesar, or the Old Guard of Napoleon. The sepoys came to Clive, not to complain of their scanty fare, but to propose that all the grain should be given to the Europeans, who required more nourishment than the natives of Asia. The thin gruel, they said, which strained away from the rice would suffice for themselves. History contains no more touching instance of military fidelity, or of the influence of a commanding mind. An attempt made by the governor of Madras to relieve the place had failed; but there was hope from another quarter. A body of 3000 Mahrattas, half soldiers, half robbers, under the command of a chief named Murari Rao had been hired to assist Mahommed Ali; but thinking the French power irresistible, and the triumph of Chanda Sahib certain, they had hitherto remained inactive on the frontiers of the Carnatic. The fame of the defence of Arcot roused them from their torpor; Murari Rao declared that he had never before believed that Englishmen could fight, but that he would willingly help them since he saw that they had spirit to help themselves. Raja Sahib learned that the Mahrattas were in motion, and it was necessary for him to be expeditious. He first tried negotiations—he offered large bribes to Clive, which were rejected with scorn; he vowed that if his proposals were not accepted, he would instantly storm the fort, and put every man in it to the sword. Clive told him, in reply, with characteristic haughtiness, that his father was a usurper, that his army was a rabble, and that he would do well to think twice before he sent such poltroons into a breach defended by English soldiers. Raja Sahib determined to storm the fort. The day was well suited to a bold military enterprise. It was the great Mahommedan festival, the Muharram, which is sacred to the memory of Husain, the son of Ali. Clive had received secret intelligence of the design, had made his arrangements, and, exhausted by fatigue, had thrown himself on his bed. He was awakened by the alarm, and was instantly at his post. The enemy advanced, driving before them elephants whose foreheads were armed with iron plates. It was expected that the gates would yield to the shock of these living battering-rams. But the huge beasts no sooner felt the English musket balls than they turned round and rushed furiously away, trampling on the multitude which had urged them forward. A raft was launched on the water which filled one part of the ditch. Clive perceiving that his gunners at that post did not understand their business, took the management of a piece of artillery himself, and cleared the raft in a few minutes. Where the moat was dry, the assailants mounted with great boldness; but they were received with a fire so heavy and so well directed, that it soon quelled the courage even of fanaticism and of intoxication. The rear ranks of the English kept the front ranks supplied with a constant succession of loaded muskets, and every shot told on the living mass below. The struggle lasted about an hour; 400 of the assailants fell; the garrison lost only five or six men. The besieged passed an anxious night, looking for a renewal of the attack. But when day broke, the enemy were no more to be seen. They had retired, leaving to the English several guns and a large quantity of ammunition."

Clive, now reinforced, followed up his advantage, and Major Lawrence returned in time to carry the war to a successful issue.

In 1754 a truce was arranged between Thomas Saunders, the company's president at Madras, and Charles Robert Godeheu, who had replaced Dupleix. The English protégé Mohammed Ali, was virtually recognized as nawab, and both nations agreed to equalize their possessions. When war again broke out in 1756, and the French, during Clive's absence in Bengal, obtained successes in the northern districts, his efforts helped to drive them from their settlements. The treaty of Paris in 1763 formally confirmed Mohammed Ali in the position which Clive had won for him. Two years later, Clive's work in Madras was completed by a firman from the emperor of Delhi, recognizing the British possessions in southern India.

The siege of Arcot at once gave Clive a European reputation. William Pitt pronounced the youth of 27 who had done such deeds a "heaven-born general." When the court of directors voted him a sword worth £700, he refused to receive it unless Lawrence was similarly honoured.

He left Madras for home, after ten years' absence, early in 1753. Before leaving India he married Margaret Maskelyne. The marriage was a happy one, and the scandalous stories of his private life spread later by his enemies are devoid of foundation. After he had been two years at home the state of affairs in India made the directors anxious for his return. He was sent out, in 1756, as governor of Fort St. David, with the reversion of the government of Madras and with the commission of lieutenant colonel in the king's army.

While at Bombay on his way to Madras, he commanded the land force which captured Gheria, the stronghold of the Maratha pirate Angria. He took his seat as governor of Fort St. David on the day on which the nawab of Bengal captured Calcutta, and thither the Madras government at once sent him, with Adm. Charles Watson.

Since the days of Job Charnock at Sutanati the infant capital of Calcutta had become a rich centre of trade. The successive nawabs, or viceroys, of Bengal had been friendly to it, till, in 1756, Suraj-ud-Dowlah succeeded his uncle at Murshidabad. His predecessor's financial minister had fled to Calcutta to escape the extortion of the new nawab, and the English governor refused to deliver up the refugee.

Enraged at this, Suraj-ud-Dowlah captured the old fort of Calcutta on June 20 and plundered it. Many of the English fled to ships and escaped down the river. The 146 who remained were forced into "the Black Hole" in the stifling heat of the sultriest period of the year; only 23 came out alive. The fleet was as strong, for those days, as the land force was weak. Disembarking his troops several miles below the city, Clive marched through the jungles, where he lost his way because of the treachery of his guides, but soon invested Fort William, while the fire of the ships reduced it, on Jan. 2, 1757.

On Feb. 4 he defeated the whole army of the nawab, which had taken up a strong position just beyond what is now the most northerly suburb of Calcutta.

The nawab hastened to conclude a treaty, under which favourable terms were conceded to the company's trade, the factories

and plundered property were restored and an English mint was established. In the accompanying agreement, offensive and defensive, Clive appears under the name by which he was always known to the natives of India, Sabut Jung, or "the Daring in War." With 600 British soldiers, 800 sepoys, 7 fieldpieces and 500 sailors to draw them, he had routed a force of 34,000 men with 40 pieces of heavy cannon and 50 elephants and seized a camp four miles in length.

In spite of his double defeat and the treaty which followed it, the madness of the nawab burst forth again. As England and France were once more at war, Clive sent the fleet up the river against Chandernagore, while he besieged it by land. After consenting to the siege, the nawab sought to assist the French, but in vain. The capture of their principal settlement in India, next to Pondicherry, which had fallen in the previous war, gave the combined forces prize to the value of £130,000. The rule of Suraj-ud-Dowlah became as intolerable to his own people as to the British. They formed a confederacy to depose him, at the head of which was Mir Jafar, his commander in chief. Associating with himself Admiral Watson, Gov. Roger Drake and William Watts, Clive made a treaty to give the office of viceroy of Bengal, Behar and Orissa to Mir Jafar, who was to pay £1,000,000 sterling to the company for its losses in Calcutta and the cost of its troops, £500,000 to the British inhabitants of Calcutta, £200,000 to the native inhabitants and £70,000 to its Armenian merchants. Up to this point all is clear. Suraj-ud-Dowlah was hopeless as a ruler. His relations alike to his master, the merely titular emperor of Delhi, and to the people left the province open to the strongest. After "the Black Hole," the battle of Calcutta and the treachery at Chandernagore, in spite of the treaty which followed that battle, the East India company could treat the nawab only as an enemy. Clive, it is true, might have disregarded all native intrigue, marched on Murshidabad and at once held the delta of the Ganges in the company's name. But the time was not ripe for this, the consequences, with so small a force, might have been fatal and the political morality of the time in Europe, as well as the comparative weakness of the company in India, led Clive not only to meet the dishonesty of his native associate by equal dishonesty but to justify his conduct by the declaration, years after, in parliament, that he would do the same again. It became necessary to employ the richest Bengali trader, Omichund, as an agent between Mir Jafar and the British officials. Master of the secret of the confederacy against Suraj-ud-Dowlah, the Bengali threatened to betray it unless he was guaranteed, in the treaty itself, £300,000. To dupe the villain, who was really paid by both sides, a second or fictitious treaty was shown him with a clause to this effect. This Admiral Watson refused to sign; "but," Clive deposed to the house of commons, "to the best of his remembrance, he [Clive] gave the gentleman who carried it leave to sign his [Watson's] name upon it; his lordship never made any secret of it; he thinks it warrantable in such a case, and would do it again a hundred times; he had no interested motive in doing it, and did it with a design of disappointing the expectations of a rapacious man."

The whole hot season of 1757 was spent in these negotiations till the middle of June, when Clive began his march from Chandernagore, the British in boats and the sepoys along the right bank of the Hooghly. That river above Calcutta is, during the rainy season, fed by the overflow of the Ganges to the north through three streams, which in the hot months are nearly dry. On the left bank of the Bhagirathi, the most westerly of these, 100 mi. above Chandernagore, stands Murshidabad, the capital of the Mogul viceroys of Bengal, and then so vast that Clive compared it to the London of his day. Several miles farther down is the field of Plassey, then an extensive grove of mango trees. On June 21 Clive arrived on the bank opposite Plassey, in the midst of that outburst of rain which ushers in the southwest monsoon of India. His whole army amounted to 1,100 Europeans and 2,100 native troops, with nine fieldpieces. The nawab had drawn up 18,000 horse, 50,000 foot and 53 pieces of heavy ordnance, served by French artillerymen. For once in his career Clive hesitated and called a council of 16 officers to decide, as he put it, "whether in our present situation, without assistance, and on our own bottom, it would be prudent to attack the nawab, or whether we should wait till joined by some country power?" Clive himself headed the nine who voted for delay; Maj. (afterward Sir) Eyre Coote led the seven who counselled immediate attack. But, either because his daring asserted itself or because, also, of a letter that he received from Mir Jafar, as has been said, Clive was the first to change his mind and to communicate with Major Coote.

One tradition, followed by Macaulay, represents him as spending an hour in thought under the shade of some trees, while he resolved the issues of what was to prove one of the decisive battles of India.

Another tradition, turned into verse by Sir Alfred Lyall, pictures his resolution as the result of a dream. However that may be, he did well to trust to the dash and even rashness that had gained Arcot and triumphed at Calcutta.

When, after the heavy rain had fallen, the sun rose brightly on June 22, the 3,200 men and the nine guns crossed the river and took possession of the grove and its tanks of water, while Clive established his headquarters in a hunting lodge. On June 23 the engagement took place and lasted the whole day. Except the 40 Frenchmen and the guns which they worked, the enemy did little to reply to the British cannonade, which, with the 39th regiment, scattered the host, inflicting on it a loss of 500 men. Clive restrained the ardour of Maj. John Kilpatrick, for he trusted to Mir Jafar's abstinence, if not desertion to his ranks, and knew the importance of sparing his own small force. He lost hardly a white soldier; in all, 22 sepoys were killed and 50 wounded. Suraj-ud-Dowlah fled from the field on a camel, secured what wealth he could and came to an untimely end. Clive entered Murshidabad and established Mir Jafar. When taken through the treasury, amid £1,500,000's worth of rupees, gold and silver plate, jewels and rich goods, and besought to ask what he would, Clive was content with £160,000, while £500,000 was distributed among the army and navy, both in addition to gifts of £24,000 to each member of the company's committee and besides the public compensation stipulated in the treaty. It was to this occasion that he referred in his defense before the house of commons, when he declared that he marvelled at his moderation. He followed a usage fully recognized by the company, although the fruitful source of future evils which he himself was again sent out to correct. The company itself acquired a revenue of £100,000 a year and a contribution toward its losses and military expenditure of £1,500,000.

Mir Jafar afterward presented Clive with the quitrent of the company's lands in and around Calcutta, amounting to an annuity of £27,000 for life, and left him by will the sum of £70,000, which Clive devoted to the army.

While busy with the civil administration, the conqueror of Plassey followed up his military success. He sent Major Coote in pursuit of the French almost as far as Benares. He dispatched Francis Forde to Vizagapatam and the northern districts of Madras, where that officer gained the battle of Condore. He came into direct contact, for the first time, with the great mogul himself, an event which resulted in the most important consequences during the third period of his career. Shah Alam, when *shahzada*, or heir apparent, quarrelled with his father, Alamgir II, the emperor, and united with the viceroys of Oudh and Allahabad for the conquest of Bengal. He advanced as far as Patna, which he besieged with 40,000 men. Mir Jafar, in terror, sent his son to its relief and implored the aid of Clive. Maj. John Caillaud defeated the prince's army and dispersed it. Finally, at this period, Clive repelled the aggression of the Dutch and avenged the massacre of Amboyna, on that occasion when he wrote his famous letter, "Dear Forde, fight them immediately; I will send you the order of council tomorrow."

Meanwhile, he never ceased to improve the organization and drill of the sepoy army, after a European model, and enlisted into it many Mohammedans of fine physique from upper India. He refortified Calcutta. In 1760, after four years of incessant labour, his health gave way and he returned to England. "It appeared," wrote a contemporary on the spot, "as if the soul was

departing from the Government of Bengal." He had been formally made governor of Bengal by the court of directors at a time when his nominal superiors in Madras sought to recall him to their help there. But he had discerned the importance of the province even during his first visit.

It should be noticed, also, that even this early he had discovered the ability of young Warren Hastings and, a year after Plassey, made him resident at the nawab's court.

In 1760, at 35 years of age, Clive returned to England with a fortune of at least £300,000 and the quitrent of £27,000 a year, after caring for the comfort of his parents and sisters and giving Major Lawrence, his old commanding officer, £500 a year. The money had been honourably and publicly acquired, with the approval of the company. The amount might have been four times what it was had Clive been either greedy after wealth or ungenerous to the colleagues and the troops whom he led to victory.

In the five years of his conquests and administration in Bengal, the young man had crowded together a succession of exploits which led Lord Macaulay, in what historians termed his "flashy" essay on the subject, to compare him with Napoleon Bonaparte. But there was this difference in Clive's favour, attributable not more to the circumstances of the time than to the object of his policy—he gave peace, security, prosperity and a certain measure of liberty to a people who had for centuries been the prey of oppression whereas Napoleon's career of conquest led to an absolutism which vanished with his fall.

He was well received at court, was made Baron Clive of Plassey, in the peerage of Ireland, bought estates and got not only himself but his friends returned to the house of commons after the fashion of the time. He then set himself to reform the home system of the East India company and began a bitter warfare with Lawrence Sulivan, chairman of the court of directors, whom in the end he defeated, aided by the news of reverses in Bengal. Henry Vansittart, his successor, having no great influence over Mir Jafar, had put Mir Kasim, the son-in-law, in his place in consideration of certain payments to the English officials. After a brief tenure Mir Kasim had fled, had ordered Walter Reinhardt (known to the Mohammedans as Sumru), a European mercenary of his, to butcher the garrison of 150 English at Patna and had disappeared under the protection of his brother viceroy of Oudh. The whole company's service, civil and military, had become demoralized by gifts and by the monopoly of the inland as well as export trade, to such an extent that the natives were pauperized and the company was plundered of the revenues which Clive had acquired for them. The court of proprietors, accordingly, who elected the directors, forced them, in spite of Sulivan, to hurry Lord Clive to Bengal with the double powers of governor and commander in chief.

What he had done for Madras, what he had accomplished for Bengal proper and what he had effected in reforming the company itself he was now to complete in less than two years, in this the third period of his career, by putting his country politically in the place of the emperor of Delhi.

On May 3, 1765, he landed at Calcutta to learn that Mir Jafar had died, leaving him personally £70,000, and had been succeeded by his son, though not before the government had been further demoralized by taking £100,000 as a gift from the new nawab; while Mir Kasim had induced not only the viceroy of Oudh, but the emperor of Delhi himself to invade Behar. After the first mutiny in the Bengal army, which was suppressed by blowing 24 sepoys from guns in the presence of their comrades, Maj. (later Sir) Hector Munro, "the Napier of those times," scattered the united armies on the hard-fought field of Buxar. The emperor, Shah Alam, detached himself from the league, while the Oudh viceroy threw himself on the mercy of the British. Clive had now an opportunity of repeating in Hindustan, or upper India, what he had accomplished in Bengal. He might have secured what were later called the United Provinces, and have rendered unnecessary the campaigns of Marquis Wellesley and Gerard (later Viscount) Lake. But he had other work in the consolidation of rich Bengal itself, making it a base for the development of the mighty fabric of British India. Hence, he returned to the Oudh viceroy all his territory save the provinces of Allahabad and Kora, which he made over to the weak emperor. But from that emperor he secured the most important document in the whole of British history in India up to that time, which appears in the records as "firmaund from the King Shah Aalum, granting the dewany of Bengal, Behar and Orissa to the company, 1765." The date was Aug. 12; the place, Benares; the throne, an English dining table covered with embroidered cloth and surmounted by a chair in Clive's tent. It is all pictured by a Mohammedan contemporary, who indignantly exclaims that so great a "transaction was done and finished in less time than would have been taken up in the sale of a jackass." By this deed the company became the real sovereign rulers of 30,000,000 people, yielding a revenue of £4,000,000 sterling.

On the same date Clive obtained not only an imperial charter for the company's possession in the Carnatic also, thus completing the work he began at Arcot, but a third firman for the highest of all the lieutenancies of the empire, that of the Deccan itself. This fact is mentioned in a letter from the secret committee of the court of directors to the Madras government, dated April 27, 1768.

Still so disproportionate did the British force seem, not only to the number and strength of the princes and people of India, but to the claims and ambition of French, Dutch and Danish rivals, that Clive's last advice to the directors, as he finally left India in 1767, was this: "We are sensible that, since the acquisition of the dewany, the power formerly belonging to the soubah of those provinces is totally, in fact, vested in the East India Company. Nothing remains to him but the name and shadow of authority. This name, however, this shadow, it is indispensably necessary we should seem to venerate."

On a wider arena, even that of the great mogul himself, the shadow was kept up till the massacre of English people in the Delhi palace in 1857; and Queen Victoria was proclaimed, first, direct ruler on Nov. 1, 1858, and later empress of India on Jan. 1, 1877.

Having thus founded the empire of British India, Clive sought to reform the administration. The civil service was deorientalized by raising the miserable salaries which had tempted its members to be corrupt, by forbidding the acceptance of gifts from natives and by exacting covenants under which participation in the inland trade was stopped.

Not less important were his military reforms. He put down a mutiny of the English officers, who chose to resent the veto against receiving presents and the reduction of *batta* (extra pay) at a time when two Maratha armies were marching on Bengal. He reorganized the army, dividing the whole into three brigades, so as to make each a complete force, in itself equal to any single native army that could be brought against it. He had not enough British artillerymen, however, and would not train natives to work the guns.

Clive's final return to England a poorer man than he went out, in spite of still more tremendous temptations, was the signal for an outburst of his personal enemies. Every civilian whose illicit gains he had cut off, every officer whose conspiracy he had foiled, every proprietor or director, like Sulivan, whose selfish schemes he had thwarted, now sought his opportunity. Clive had, with consistent generosity, at once made over the legacy of £70,000 from the grateful Mir Jafar as the capital of what has since been known as "the Clive fund" for the support of invalided European soldiers, as well as officers, and their widows; and the company had allowed 8% on the sum for an object which it was otherwise bound to meet.

Gen. John Burgoyne, of Saratoga memory, did his best to induce the house of commons, in which Lord Clive was now member for Shrewsbury, to impeach the man who gave his country an empire, and the people of that empire peace and justice. The result, after the brilliant and honourable defenses of his career which will be found in John Almon's *Debates* for 1773, was a compromise. On a division the house, by 155 to 95, carried the motion that Lord Clive "did obtain and possess himself" of £234,000 during his first administration of Bengal; but, refusing to express an opinion on the fact, it passed unanimously the

second motion, at five in the morning, "that Robert, Lord Clive, did at the same time render great and meritorious services to his country." The one questionable transaction—the Omichund treaty—was not touched.

Only one who can personally understand what Clive's power and services had been will rightly realize the effect on him, though in the prime of life, of the discussions through which he had been dragged.

In the greatest of his speeches, in reply to Lord North, he said, "My situation, sir, has not been an easy one for these 12 months past, and though my conscience could never accuse me, yet I felt for my friends who were involved in the same censure as myself . . . I have been examined by the select committee more like a sheep-stealer than a member of this House." Clive's end was the result of physical suffering, of chronic disease which opium failed to abate and which the worry and chagrin caused by his enemies exacerbated; he died by his own hand on Nov. 22, 1774, in his 50th year.

Clive was slightly above middle size, with a countenance rendered heavy and almost sad by a natural fullness above the eyes. His encouragement of scientific undertakings like Maj. James Rennell's surveys, and of philological researches like Francis Gladwin's, gained him the honorary distinctions of F.R.S. and LL.D.

His son and successor Edward (1754–1839) was created earl of Powis in 1804, his wife being the sister and heiress of George Herbert, earl of Powis (1755–1801). He thus was the ancestor of the later earls of Powis, who took the name of Herbert instead of that of Clive in 1807.

See G. W. Forrest, *Life of Lord Clive* (London, 1918); H. H. Dodwell, *Dupleix and Clive* (London, 1920).

CLOACA, the Latin term for a drain or sewer. The most famous is the Cloaca Maxima at Rome, built to drain the marsh where the Forum Romanum was situated. Constructed originally in the late 6th century B.C. as an open stone-lined channel, some side channels were vaulted in the 5th century and the main channel in the 3rd century and later with a stone barrel vault.

CLOACA is also the name given to the joint opening of the urinogenital and alimentary systems characteristic of all the vertebrates except the mammals, among which it is only retained in the Monotremata (*q.v.*).

CLOCKS. A clock is a machine designed to record and to indicate the passing of time. The only way to construct such a machine is to link a device that performs regular movements in equal intervals of time to a counting mechanism that will record the number of these movements. All clocks, of whatever form they may be, are made on this principle.

An ordinary clock consists of a series of toothed wheels and pinions (small toothed wheels) driven by a weight or spring and linked by an escapement to a pendulum or, alternatively, to a balance and hairspring, which has the property of even, isochronous motion. The function of the escapement is to enable the regular movements of the pendulum or balance to control the rotation of the wheelwork and to cause it to rotate at an even and constant rate. At the same time, the escapement is arranged to transmit to the pendulum or balance sufficient power to maintain its swing by replacing the energy absorbed by various frictional effects. Such a machine, though popularly called a clock, is strictly termed a timepiece, the term clock being properly applied only to a timekeeper which, by an additional mechanism, strikes the hours on a bell or gong (French *cloche*, German *Glocke*, bell).

The earliest mechanical clocks seem to have been introduced in Europe during the 13th century and were employed in religious houses to mark the times of services. A clock is said to have been erected at Westminster in 1288, another at Canterbury in 1292 and another, with an astronomical dial, at St. Albans in 1326. The oldest clock remaining in England is that at Salisbury cathedral, which dates from 1386; another still existing mechanism was erected at Wells cathedral in 1392. Others of somewhat later date are to be seen at Exeter cathedral, at Ottery St. Mary church, at Rye church and at Cothele house in Cornwall. None of these early clocks was originally fitted with a pendulum. Instead, they had a verge or crown-wheel escapement controlled by two weighted arms which oscillated slowly and so controlled the release of the escape wheel. This device was known as a foliot (*see* fig. 1).

As the time of swing of the arms was very variable and was directly affected by the driving force, these early clocks were very poor timekeepers and often varied by as much as an hour in a day. The action of the foliot can be followed from the illustration (fig. 1). A and B are the weighted arms, which pivot at the point C; the escape wheel E is released, tooth by tooth, by the movement of the two pallets F and G, which are mounted on the same axis as the arms A and B and swing with them; from this it will be seen that the escape wheel is not only released by the motion of the arms and pallets but also transmits to them some of the energy of the driving weight H and so maintains their swing.

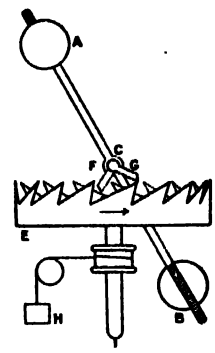

FIG. 1.—VERGE ESCAPEMENT, SHOWING THE METHOD OF USING AN OSCILLATING MASS TO KEEP TIME

Pendulum.—The next important development in clock construction was the introduction of the pendulum. Its principle was first discovered by Galileo in 1581. It consists of a weight or bob mounted on the lower end of a vertical rod. The upper end of this rod is suspended from a flexible support in such a manner that the rod and its bob are free to oscillate under the influence of gravity.

The great virtue of a pendulum as a time measurer lies in the fact that, within certain limits, its period of swing remains practically unaffected by variations in the degrees of arc through which it swings. The duration of swing of a pendulum varies with its length; in Great Britain the length of a pendulum which makes one swing per second is 39.14 in. With such a pendulum, an increase in length of about $\frac{1}{1,000}$ in. will cause a change in rate of about a second a day, and if the arc of vibration is 3 in. an increase of $\frac{1}{10}$ in. will have a similar effect.

The relation between the length of a pendulum and its time of swing can be determined by the following formula. Consider L to be the length of the pendulum in feet, G the acceleration caused by gravity in feet per second per second and π the ratio of the circumference of a circle to its diameter (= approx. 3.1429): then the time of one swing in seconds $= \pi \sqrt{\frac{L}{G}}$.

As the time of swing of a pendulum is so critically dependent on its length, it follows that any expansion or contraction of the rod caused by changes of temperature will affect its timekeeping. For instance, the expansion of steel is approximately 0.001 in. for every 4° of increase in temperature, and a corresponding decrease will result in a proportional contraction. If accurate timekeeping is required, a pendulum must be compensated for such changes by some device which will keep its length as constant as possible at all times. There are several ways in which this may be done, some of which use the differing coefficients of expansion of different metals to obtain a cancelling-out effect. The most usual forms of compensation are the mercurial, where the bob contains a suitable amount of mercury, the gridiron, where brass and steel rods are employed, and the zinc-iron tube, in which, as the name suggests, the pendulum rod is made up of concentric tubes of zinc and iron.

A better method is the use of a special alloy called Invar for the pendulum rod. This material has such a small coefficient of expansion that changes of temperature have an almost negligible effect.

Escapement.—This important part of the mechanism of a timekeeper has the dual function of controlling the wheel train of a clock by relating its speed of rotation to the evenly timed swings of the pendulum or balance and of supplying the pendulum or balance with enough energy to maintain its swing. An ideal escapement would perform both functions without any interference with the free swing of the pendulum or balance, and the more

closely an actual escapement approaches this condition, the better it is.

When first introduced, the pendulum was used with the verge escapement. This was as shown in fig. 1, but adapted to pendulum control. In a short time, the verge was replaced by the anchor or recoil escapement, which was a great improvement and is still used for many domestic clocks (fig. 2).

The recoil escapement has two pallets, which are mounted on the ends of a curved bar or yoke that spans a part of the circumference of the escape wheel. At a point approximately equidistant from both pallets, the yoke is attached to a pivoted spindle linked to the pendulum by a light bar or crutch. As the pendulum swings it causes the pallet spindle to move with an oscillating movement, and this in turn engages and disengages the pallets with the teeth of the escape wheel, so permitting the wheel to advance in a step-by-step motion.

FIG. 2.—ANCHOR OR RECOIL ESCAPEMENT, ONE OF THE EARLIEST ATTEMPTS TO USE A PENDULUM

The inclined acting faces of the pallets not only arrest and release the teeth of the escape wheel, but also serve to transmit some of the energy used to drive the clock to the pendulum in the form of impulses. Because of their form, however, the pallets also cause any additional swing which the pendulum makes after a tooth has engaged with a pallet to cause a recoiling movement of the escape wheel. This must be considered a defect, and to obviate the recoil a modification, known as the deadbeat escapement, was invented by George Graham in 1715 (fig. 3).

In this escapement the acting surfaces of the pallets are shaped to have two distinct parts, known as the dead and impulse faces. The teeth of the escape wheel fall first upon the dead faces (GF and BD, fig. 3) and rest upon them before the movement of the pallets allows them to reach the impulse faces (FA and BE, fig. 3) and finally to escape. As the dead faces of the pallets are formed as parts of the arc of a circle struck from the pivot point (C, fig. 3) any additional swing of the pendulum after the engagement of a tooth with a pallet will not cause any recoil, and the swing of the pendulum will not be interfered with to any great extent. To minimize interference still further by reducing friction the pallets of very precise clocks have pieces of jewel inserted in their acting faces.

The pallets of a deadbeat escapement usually embrace about one-third of the circumference of the escape wheel, for this arrangement gives the best possible action and does not make the pallets unnecessarily heavy. With this construction, a total of about 2°—about 1° on each side of the vertical—is occupied in receiving the impulse. As the total arc of swing of the pendulum is about 3°, this is a very satisfactory arrangement.

Other versions of the deadbeat escapement include the pin-pallet and pin-wheel forms, the latter being often used for small tower clocks where extreme accuracy is not essential.

One of the defects of both the recoil and deadbeat escapements is that the impulse that they transmit to the pendulum can vary because of variations in the power transmitted by the wheelwork of the clock. Such changes in power can arise from thickening of the oil, from dust or wear or, in the case of tower clocks, from wind pressure or from snow or ice on the hands. To overcome this a number of inventors designed escapements in which weighted arms were raised by the escape wheel and then delivered the impulse to the pendulum as they descended to their original position. The first really successful escapement of this kind was invented by Bloxam, a barrister. A much better form, the double three-legged gravity escapement, was invented by E. B. Denison, afterward Lord Grimthorpe, and used by him for the great clock at Westminster. It has since become standard for all really accurate tower clocks (fig. 4).

In this escapement, the escape wheel is made up of two three-legged components (C_1 and C_2) mounted 60° apart on their spindle. Between these two wheels, at a point near their centre, are three pins (P_1, P_2 and P_3) known as the lifting pins. Engaging with the wheels and the pins are two gravity arms (A_1 and A_2) pivoted at their upper ends and carrying locking pads (B_1 and B_2), one of which engages with the tips of wheel C_1, the other with the tips of wheel C_2. On the gravity arms are the projecting arms E_1 and E_2, which engage with the lifting pins and form the means by which the gravity arms are raised.

The action is as follows. As the escape wheel rotates a sixth of a turn, one of the lifting pins (P_1 in fig. 4) raises a gravity arm and then, at the moment when the arm is lifted fully, the corresponding leg of the three-legged wheel (C_2 in fig. 4) locks on its pad on the arm, so arresting further movement of the escape wheel. The swinging pendulum then engages with the lower end of the gravity arm and lifts it slightly farther. This unlocks the escape wheel by moving the locking pad from under the tip of the wheel tooth, and the wheel turns a further sixth of a turn. As this occurs, the pin is moved out of contact with the projecting arm E_2 on the gravity arm which it has been supporting. The arm is then free to fall back with the pendulum and, as it returns, it delivers to the pendulum the energy which was stored in it when the escape wheel raised it. As one gravity arm is unlocked, the other is raised by another pin (P_2 in fig. 4) and locked by the other section of the double three-legged wheel, after which the whole cycle is repeated. In other words, the pendulum always finds the gravity arms lifted to a higher level than it left them, and the weight of the arms, falling through this distance, delivers the impulse. As it is a gravitational impulse, it is, of course, constant in value.

Many of the smaller types of domestic clock are now being fitted with escapements embodying a balance and hairspring instead of a pendulum, the object being to make them more portable. The escapements used are the cylinder, lever and, in some cases, the chronometer detent (*see* WATCHES). Their construction is identical with similar escapements used in watches.

Clock Wheelwork: the Train.—With all but the gravity escapement, it is of great importance that the energy transmitted by the wheelwork of a clock should be as regular as possible and, even with a gravity escapement, a consistent supply of power is an advantage. The wheels and pinions should therefore be made as accurately as possible, and the tooth form designed so that the transference of power takes place as steadily as conditions permit. Modern improvements in manufacture and advances in the theory of gear design have made clocks of the present day far better than older ones in this respect. In a weight-driven or spring-driven clock, the power of the weight or spring is first transmitted by the great or main wheel. This engages with the first pinion, to the spindle of which is attached the second wheel. This engages with the second pinion, and so on, right through the train and down to the escapement. The ratios of the gears are such that one spindle, usually the second or third, rotates at a speed of one turn per hour, and so can be used to carry the minute hand. A simple 12 to 1 gearing, known as the motion work, gives the necessary step-down ratio to drive the hour hand. The spring or weight is fitted with some form of ratchet mechanism to enable it to be rewound when necessary, and the spindle carrying the minute hand is provided with a simple slipping clutch which allows the hands to be set to time.

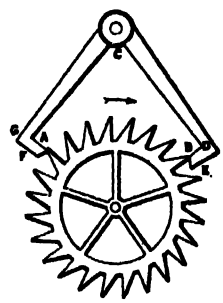

FIG. 3.—DEADBEAT ESCAPEMENT, A REFINEMENT OF THE ANCHOR ESCAPEMENT

In many modern clocks, the mainspring is enclosed in a drum or barrel which has the main wheel mounted directly on one end. As, with this arrangement, the spring is then wound by the rotation of the spindle or arbor on which the barrel pivots, the power of the spring still acts on the wheelwork during winding and a special attachment to maintain the power is unnecessary.

On weight-driven clocks and some forms of spring-driven clocks, however, the act of winding interrupts the supply of power, and such clocks must have a maintaining power if their

timekeeping is not to be interfered with. In some maintaining-power mechanisms, a small spring or weight is attached to a lever in such a way that it can be brought into action during winding, the power of the additional spring or weight taking over the propulsion of the clock until the process is completed. Many tower clocks have such an arrangement. For domestic clocks, a better form of maintaining power is the Harrison going ratchet (fig. 5).

Here the pawl or click (R) of the winding ratchet (B) is not mounted on the main wheel (G) but is pivoted instead on a second, larger ratchet, whose teeth point the opposite way. Engaging with the teeth of this second ratchet wheel is another pawl or click (Tr) pivoted to the frame of the clock. The second ratchet wheel is linked to the main wheel (G) by a spring (ss'), one end of which (s) is attached to the ratchet and the other (s') to the main wheel. During the normal going of the clock, the driving weight stores power in this spring, and the whole assembly rotates with the main wheel, the pawl Tr stepping idly over the teeth of the larger ratchet wheel (hence the term going ratchet).

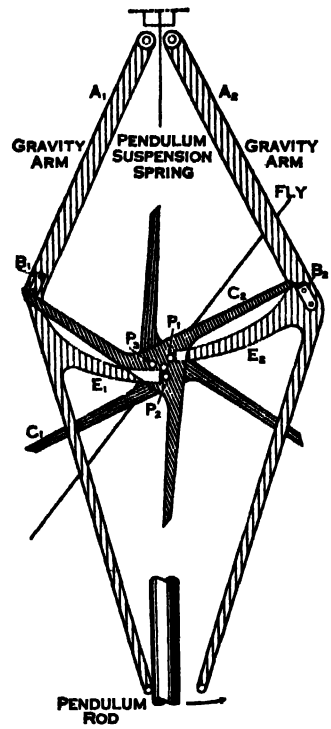

FIG. 4.—GRIMTHORPE DOUBLE THREE-LEGGED GRAVITY ESCAPEMENT AS USED FOR LARGE TOWER CLOCKS

When winding begins, the winding ratchet (B) is rotated, and the power of the weight ceases to be applied to the train, but as the second pawl (Tr) locks the larger ratchet wheel and prevents it from moving with the winding ratchet (B), the power stored in the spring (ss') still acts on the main wheel through the end (s') of the spring. This power, applied to the slowly moving main wheel, is enough to keep the clock going during the time required to wind up the weight.

Construction of an Ordinary Clock.—The general construction of the timekeeping part of all clocks, including large tower clocks, is substantially the same. Fig. 6 shows the side view of a simple weight-driven timepiece with a pendulum. The frame is made up of two plates which carry the pivots of the various wheels and other moving parts and are united and spaced by four pillars (P). The driving weight (W) hangs from a line coiled around the barrel (B) and is wound by means of the ratchet wheel (R). Between this ratchet and the main wheel (G) is the maintaining-power ratchet, similar to that described in fig. 5, the arbor of the going ratchet being visible at Tr. The main wheel (G) engages with the centre pinion (c) on the spindle of which is also mounted the centre wheel (C). The front pivot of this wheel and pinion is lengthened to the left of the illustration, and carries the minute hand and part of the gearing necessary to drive the hour hand.

The centre wheel (C) engages with the pinion of the third wheel (d) and on that same spindle is mounted the third wheel (D) which in its turn engages with the escape wheel pinion (e). The escape wheel (E) engages with the pallets (A) which are fixed to the spindle (a) and pivot between the front plate and the pendulum suspension cock (F). Also fixed to the pallet spindle is the crutch (Ff), which terminates at its lower end in a fork (f) which embraces the pendulum rod (Pp). This pendulum, of which only the upper part is shown, is suspended by a thin flat suspension spring (S) from the cock (F) which is reinforced to obtain the utmost possible rigidity by a bar (QO) spanning the top of the clock frame plates.

The motion work used for driving the hands at their relative speeds is mounted between the dial and the front plate of the frame. The wheel (M), which rotates once per hour and is known as the cannon pinion, is coupled to the centre spindle by a flat spring which acts as a clutch and permits the hands to be set. The cannon pinion (M) engages with a wheel of similar size (N) called the minute wheel, and the small pinion (n) attached to this wheel engages with the hour wheel (H) that pivots on a small supporting bar or bridge (L). The winding square (K) is shown projecting through a hole in the dial plate, and the attachments of the dial plate to the mechanism are at x and Z.

Striking Mechanism.—The striking mechanism of a clock consists of an extra train of wheels, usually mounted in the same frame but quite distinct in construction, which is used to announce the hours by striking them on a bell or gong. It is, in fact, a hammer-lifting mechanism equipped with a counting device which governs the number of blows struck. It is released by the action of the timekeeping part, but has little or no other connection with it.

There are two forms of controlling mechanism for determining the number of blows to be struck at the various hours. One is known as the locking plate and the other the rack. The former is the older and is still used for most tower clocks. The other, the rack mechanism, is used on most domestic clocks, and the usual arrangement for an English long-case or grandfather clock is shown in fig. 7. On the hour-wheel pipe (M), which is rotated by the hour wheel (H), is a 12-stepped snail (Y). Pivoted on the front plate is a rack (R) in which are cut a number of teeth (L) and this rack also has a tail (V) which, when it is allowed to fall onto the snail (Y), determines the distance that the rack can move. Mounted on an extended pivot of the third wheel of the striking train is a gathering pallet (G), which can engage with the teeth on the rack and gather them, a tooth at a time, one tooth being gathered for each rotation of the gathering pallet. Also engaging with the teeth on the rack is a form of ratchet pawl called a rack hook (C), and this allows the gathering pallet to gather the rack teeth but prevents them from dropping back between the gathering of successive teeth. Also mounted on the gathering pallet is a tail (K) which, when the last tooth of the rack has been gathered, engages with a pin on the rack and so locks the striking mechanism.

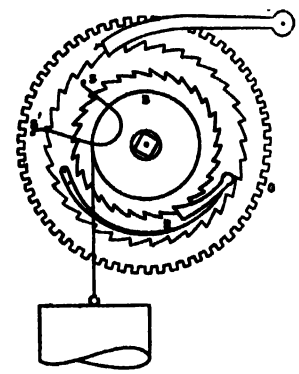

FIG. 5.—HARRISON'S GOING-RATCHET MAINTAINING POWER, WHICH KEEPS A WEIGHT-DRIVEN CLOCK GOING WHILE IT IS BEING WOUND

The striking hammer, seen on the left of the diagram, is pivoted between the frame plates of the clock and is raised during the action of the striking train by pins (x) set in the rim of the second wheel of the striking train and engaging with the hammer tail (T). The ratio of the third wheel to the second is such that the third wheel makes one rotation every time a pin on the second wheel raises and releases the striking hammer. From this it will be understood that one tooth of the rack is gathered for each blow struck on the bell.

The sequence of action is as follows. As the minute wheel (N), which turns once an hour, rotates, a pin set in it engages with and rocks the warning detent (O) and causes the end of it lying under the rack hook (C) to rise. This lifts the rack hook out of engagement with the teeth on the rack and, at the same time, brings the tip of the warning detent (O) into a position where it can catch a pin (P) set in the rim of the fourth wheel of the striking train. As the warning detent lifts the rack hook clear of the teeth in the rack, the latter is freed and drops back under the pressure of its spring until its tail (V) comes to rest on the step of the snail (Y) which happens to be in line with it. If the tail drops onto the highest step of the snail, the rack will only be al-

lowed to drop back a distance of one tooth, but if the tail falls on the lowest step, the rack will drop back 12 teeth. As the snail is mounted on the hour wheel and moves round with the hour hand, it will be seen that the rack tail will drop on consecutive steps of the snail at each successive hour and will thus cause the rack to fall back the right number of teeth to strike the right hour.

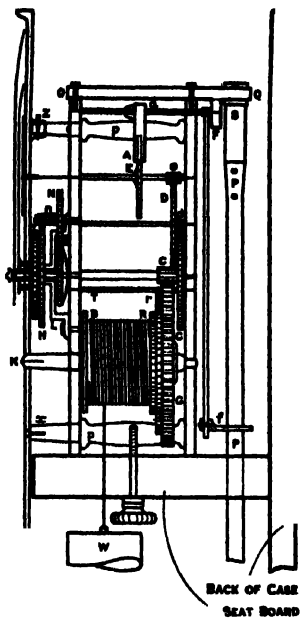

FIG. 6.—SIDE VIEW OF A WEIGHT-DRIVEN HOUSE CLOCK WITHOUT STRIKING MOVEMENT

As the movement of the pin on the minute wheel (N) continues to lift the warning detent (O) and with it the rack hook (C) the rack is freed and drops. This disengages the pin on its end from the tail (K) of the gathering pallet (G) and so unlocks the wheelwork. This then runs forward until the pin (P) on the fourth wheel engages with the tip of the warning detent (O). This constitutes the warning, a feature necessary to ensure the precise release of the striking at the hour. When the rack has dropped the correct distance the pin on the minute wheel (N) moves past and releases the warning detent (O). The detent then falls and its tip releases the warning pin (P). The striking now proceeds and each time the hammer strikes the bell, the gathering pallet gathers one tooth of the rack and the rack hook holds it. When the gathering pallet reaches the last tooth of the rack the striking train locks and comes to rest until the next hour. Other lettered parts on the diagram are as follows: S is the hammer return spring which causes it to strike on the bell when released; Si-St is the strike-silent lever, which when raised prevents the rack from dropping and so silences the clock; F is the tail of the warning detent, to which is attached a cord that can be pulled to make the clock restrike the last hour sounded; Qg is another silencing device which holds the warning detent down when desired. The vane seen at the upper left-hand corner of the frame is the fly, an air brake which governs the speed of rotation of the striking train.

Tower Clocks.—These are large timekeepers used to indicate time from dials mounted on the outside of a church or other building. In former times their construction was virtually an enlarged version of that of a domestic clock, and their frames were made up of an assembly of bars fastened together in a sort of cage. For this reason, they were known as birdcage-frame clocks. The standard form of frame now in use is the flat bed, in which the main part is a massive casting resembling a table or platform. The bearings of the various wheels are separately bolted to this casting in such a way that almost every part can be dismantled separately. The adoption of this improved design was largely due to Lord Grimthorpe, who used it for the great Westminster clock. In basic design, the timekeeping and striking parts of a tower clock do not differ very much from those of smaller clocks, except that the gravity escapement is nearly always fitted and the striking mechanism (and the chiming mechanism also, if there is one) is controlled by a locking plate instead of a rack.

Hand-wound tower clocks are invariably driven by weights, which are usually wound up to the full height of the tower, but in recent times automatically wound types, in which a light weight is hung from an endless length of roller chain and rewound at fairly frequent intervals by an electric motor, have become almost standard where electric current is available. Such a timekeeper, if fitted with a gravity escapement and an Invar pendulum, is practically ideal.

In most of these modern autowound clocks, the striking and chiming mechanisms are directly driven by electric motors which raise their hammers by suitable cams that are rotated by the final spindle of an enclosed reduction gearing. In these instances the locking plate counting mechanism is arranged to switch off the motor when the correct hour or quarter is struck.

In some tower clocks the timepiece has no pendulum and escapement of its own but is arranged to be released in half-minute steps by a trigger release device that is controlled by an electromagnet connected to a precision master clock. This is a very good arrangement, for it enables very large dials to be driven accurately and reliably and is remarkably simple in construction. A good example of this type is the great Shell-Mex clock on the Victoria embankment, London, where two 25-ft. dials are operated with ease.

Some tower clocks have been made which are driven by synchronous electric motors operated from the alternating current supply mains, but this does not seem to be a good arrangement for even a momentary interruption of the supply will stop the clock, and changes in frequency of the alternating current will cause variations in timekeeping.

Electric Clocks.—By this term master clocks which drive large numbers of subsidiary impulse dials are intended. These are rapidly gaining popularity because of their simplicity, reliability and low cost of upkeep. They are also extremely accurate when properly regulated. In general, they consist of a pendulum which

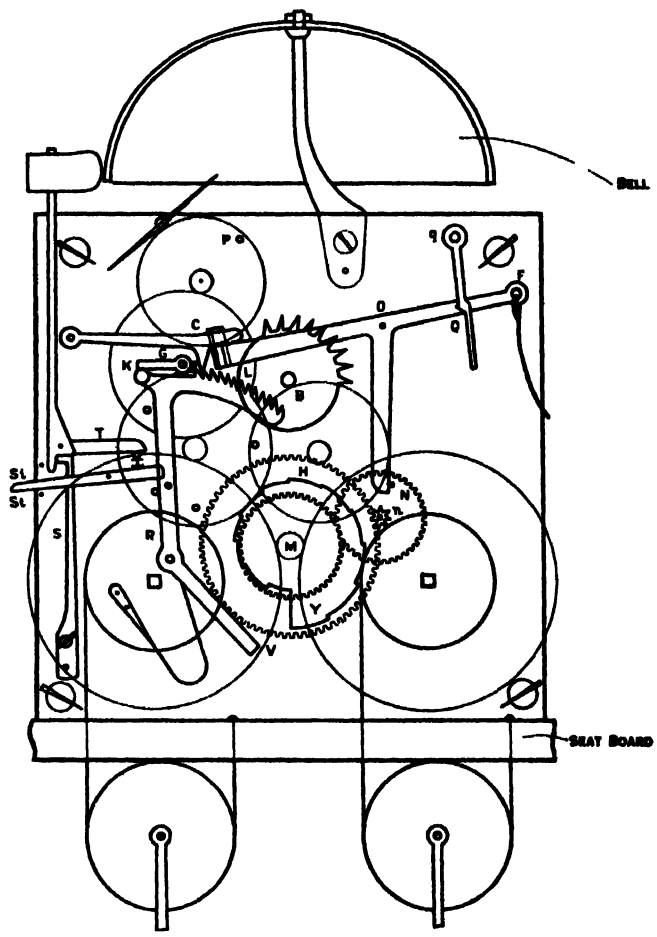

FIG. 7.—DIAGRAM OF FRONT VIEW OF ENGLISH LONG-CASE CLOCK WITH STRIKING MOVEMENT

beats 1 second per swing and rotates a small 15-toothed wheel once in every 30 seconds. As the wheel completes its rotation, it trips a catch and allows a gravity arm to fall onto the pendulum, thus giving the latter its maintaining impulse. As the gravity arm reaches its lowest point it closes an electrical contact and is immediately replaced on its catch by an electromagnet. It then rests there until the end of the next half minute, when the cycle is repeated.

The impulse dials, of which there may be any number, are simple mechanisms in which a 120-toothed wheel is stepped forward every half minute by the same electric impulses that replace the gravity arm of the master clock. In the impulse dials, these impulses step a ratchet pawl into the next tooth of the 120-toothed wheel and so propel the hands. The main advantage of this system is its theoretical perfection, for its basic principles are markedly sound. This is demonstrated by the fact that, with modifications, it is used in the Shortt free pendulum clock, the most accurate pendulum clock in the world.

Synchronous Electric Clocks.—These form the most recent development in domestic timekeepers and, provided that a source of alternating current of controlled frequency is available, they are good enough from a timekeeping standpoint to be used for most purposes. They consist of a small electric motor of the type known as synchronous coupled to a reduction gearing. As the term synchronous suggests, the rotor of the motor turns in exact step with the frequency of the alternating current and, if the frequency is maintained at a predetermined number of cycles per second and a suitably designed reduction gear links the motor to the clock hands, these will show the correct time. Synchronous clocks are not really clocks in the true sense, for they are merely frequency meters that repeat the time transmitted to them by the power station. They also have the defect of departing from the correct time if the frequency of the current varies.

Quartz Crystal Clocks.—In these, the latest development in precision timekeeping, a piece of quartz crystal replaces the pendulum as the standard time measurer. The crystal is kept in a state of electrical vibration and is able to control the frequency of an alternating current of a very special kind. This current is, in turn, fed to a submultiple generator, which is a kind of electrical reduction gear, and the reduced frequency current from this is used to drive a high-frequency type of synchronous clock. Quartz crystal clocks are very accurate, but in the mid-1950s they were still distinctly specialized timekeepers and it seemed doubtful if they would ever have any domestic applications.

(T. R. B. R.)

THE CLOCK IN DECORATION

In art the clock occupies a position of considerable distinction, and antique examples are prized and collected as much for the decorative qualities of their cases as for the excellence of their timekeeping. English and French cabinetmakers have especially excelled, although in entirely different ways, in the making of clock cases. The one aimed at comely utility, often made actually beautiful by fit proportion and the employment of finely grained woods; the other sought a bold and dazzling splendour in which ornament overlay material. It was not in either country until the latter part of the 17th century that the cabinetmaker's opportunity came. The bracket or chamber clock gave comparatively little scope to the worker in wood—in its earlier period, indeed, it was almost invariably encased in brass or other metal; and it was not until the introduction of the long pendulum swinging in a small space that it became customary to encase clocks in decorative woodwork. What is, perhaps, the earliest surviving English specimen of grandfather clock is inscribed with the date 1681. Originally it was a development of the dome-shaped bracket clock, and in the older examples the characteristic dome or canopy is preserved. The first timekeepers of this type had oaken cases but when walnut began to come into favour that beautifully marked wood was almost invariably used for the choicest and most costly specimens. Thus in 1698 the dean and chapter of St. Paul's cathedral paid the then very substantial price of £14 for an inlaid walnut long-cased eight-day clock to stand in one of the vestries. Throughout the 18th century they were made in myriads all over England, and since they were a prized possession it is not surprising that innumerable examples have survived. Vary as they may in height and girth, in wood and dial, they are all essentially alike. In their earlier years their faces were usually of brass engraved with cherubs' heads or conventional designs, but eventually the less rich white face grew common. There are two varieties—the eight-day and the 30-hour. The favourite walnut case of the late 17th and early 18th centuries gave place in the course of a generation to mahogany, which retained its primacy until the introduction of cheaper clocks brought about the supersession of the long-cased variety. Many of these cases were made in lacquer when that material was in vogue; satinwood and other costly foreign timbers were also used for bandings and inlay. The most elegant of the grandfather cases are, however, the narrow-waisted forms of the William and Mary period in walnut inlay, the head framed in twisted pilasters. During the later period of their popularity the heads of long clocks were often filled in with painted disks representing the moon, by which its course could be followed. Such conceits as ships moving on waves or time with wings were also in favour. The northern parts of France likewise produced tall clocks, usually in oaken cases; those with Louis XV shaped panels are often very decorative. French love of applied ornament was, however, generally inimical to the rather uncompromising squareness of the English case, and the great Louis XV and Louis XVI cabinetmakers made some magnificent and monumental clocks, many of which were long only as regards the case, the pendulum being comparatively short, while sometimes the case acted merely as a pedestal for a bracket clock fixed on the top. These pieces were usually mounted very elaborately in gilt bronze, cast and chased, and French bracket and chamber clocks were usually of gilded metal or marble or a combination of the two; this essentially late 18th-century type still persists. English bracket clocks contemporary with them were most frequently of simple square or arched form in mahogany. The grandfather case was also made in the Low Countries, of generous height, very swelling and bulbous.

CLODIA, VIA, an ancient highroad of Italy. Its course, for the first 11 mi., was the same as that of the Via Cassia; it then diverged to the north-northwest and ran on the west side of the Lacus Sabatinus, past Forum Clodii and Blera (modern Bieda) to Tuscania, after which its course is uncertain. According to Millee (*Itineraria Romana*) it went on by Maternum (Valentano) Acquapendente, Radicofani, Buonconvento Siena and Lucas past another Forum Clodii to Luna, but this is doubtful. In parts it follows older Etruscan roads, and may date from the end of the 4th century B.C. *See* also CASSIA, VIA.

See D. Anziani in *Mélanges de l'École Française de Rome,* 169 *sqq.* (1913).

CLODIUS, PUBLIUS (*c.* 93–52 B.C.), surnamed PULCHER, Roman politician. He took part in the third Mithridatic War under his brother-in-law Lucius Licinius Lucullus but, considering himself treated with insufficient respect, he stirred up a revolt; another brother-in-law, Q. Marcius Rex, who was governor of Cilicia, gave him the command of his fleet, but he was captured by pirates.

On his release he repaired to Syria, where he nearly lost his life during a mutiny instigated by himself. Returning to Rome in 65, he prosecuted Catiline for extortion, but was bribed by him to procure acquittal. There seems no reason to believe that Clodius was implicated in the Catilinarian conspiracy; according to Plutarch he supported Cicero. But Cicero attacked him when he was on trial for profaning the mysteries of the Bona Dea (61), and this made Clodius his enemy for life and he became the tool of Caesar.

On his return from Sicily (where he had been quaestor in 61) he was adopted by a plebeian and elected tribune of the people (59). His first act was to bring forward certain laws calculated to secure him the popular favour. Corn was to be distributed gratuitously once a month; the magistrates' right of preventing the assembly of the comitia was abolished; the old guilds of work-

men were re-established; the censors were forbidden to exclude any citizen from the senate or inflict any punishment upon him unless he had been publicly accused and condemned. He then contrived the exile of Cicero and the dispatch of the younger Cato on a mission to Cyprus. Cicero's property was confiscated by order of Clodius. After the departure of Caesar for Gaul, Clodius became practically master of Rome by means of his armed gangs. But he fell out with Pompey and was not re-elected for 57, while one of the tribunes, Milo, countered his force with force, so despite his opposition, in Aug. 57 Cicero was recalled. Riots between Clodius and Milo continued; in 56, when *curule aedile*, Clodius impeached Milo for public violence (*de vi*), but the matter was dropped.

In 53, when Milo was a candidate for the consulship, and Clodius for the praetorship, the rivals collected armed bands and fights took place in the streets of Rome, and on Jan. 20, 52, Clodius was slain near Bovillae.

His sister, CLODIA, wife of Q. Caecilius Metellus Celer, was notorious for her numerous love affairs. It is now generally admitted that she was the Lesbia of Catullus (Teuffel-Schwabe, *Hist. of Roman Lit.*, Eng. tr., 214, 3). For her intrigue with M. Caelius Rufus, whom she afterward accused of attempting to poison her, *see* Cicero, *Pro Caelio*.

CLOGHER, a village, County Tyrone, Northern Ireland. Pop. (1951) 192. It gives its name to dioceses of the Church of Ireland and the Roman Catholic Church, though the seat of the bishop of the latter is at Monaghan.

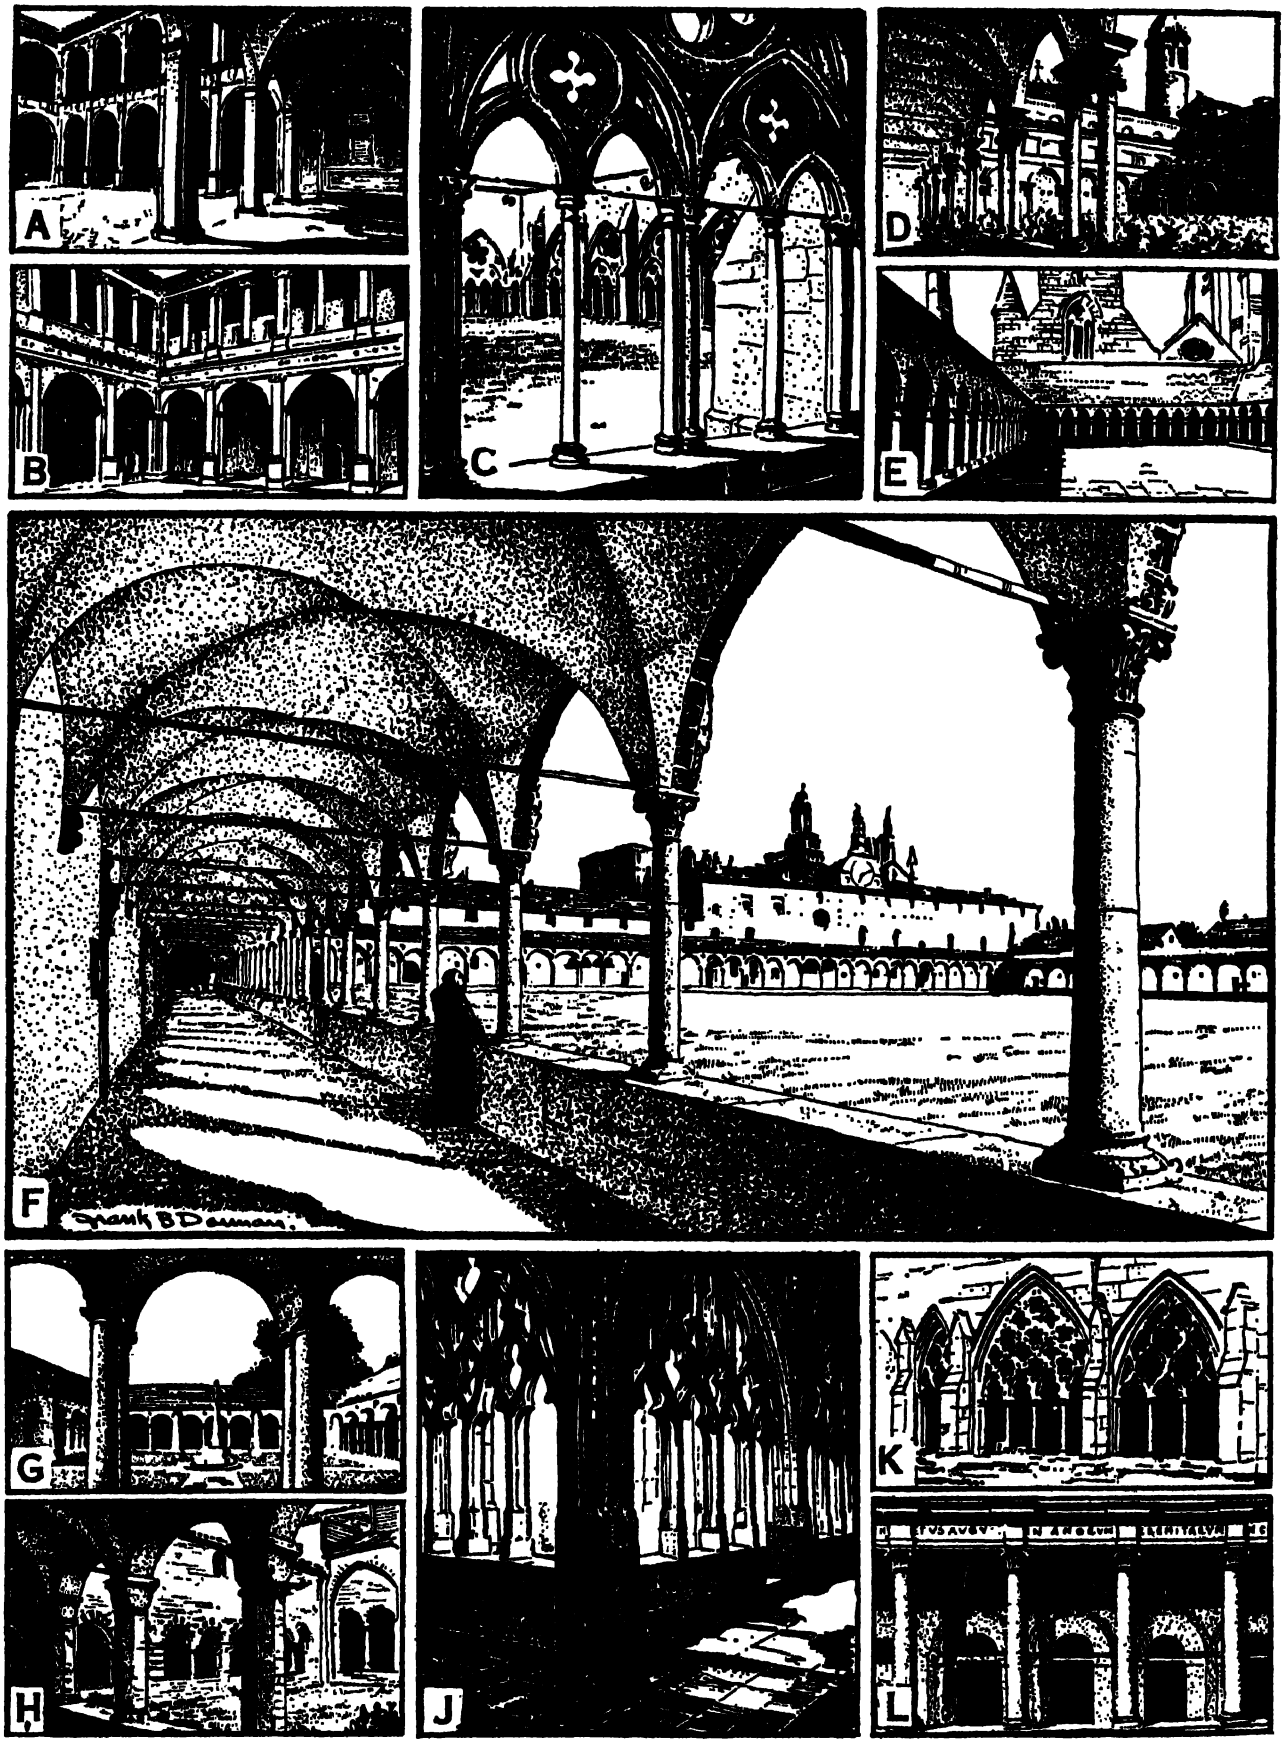
The dedication of the Protestant cathedral to St. Macartin is of interest, for although the building is modern, St. Macartin is associated with St. Patrick, who is said to have founded a bishopric there.

The name is derived from *cloch*, a pillar stone—an object of worship in the locality, preserved in the cathedral until the 15th century.

CLOISTER originally signified an entire monastery, but is now restricted to mean the four-sided enclosure, surrounded with covered ambulatories, usually attached to conventual and cathedral churches and sometimes to colleges, or, by a still further limitation, to the ambulatories themselves. In its older sense it is frequently used in earlier English literature and is still so employed in poetry.

The Latin *claustrum*, as its derivation implies, primarily denoted the enclosing wall of a religious house and then came to be used for the whole enclosed building. To this sense the German *Kloster* is still limited, the covered walks or cloister in the modern sense being called *Klostergang*, or *Kreuzgang*. In French the word *cloître* retains the double sense. In the special sense now most common, the word "cloister" denotes the quadrilateral area in a monastery or college, round which the principal buildings are ranged, and which is usually provided with a covered way or ambulatory running all round and affording a means of communication between the various centres of the ecclesiastical life. According to the Benedictine arrangement, which from its suitability to the requirements of monastic life was generally adopted in the west, one side of the cloister was formed by the church, the refectory occupying the side opposite to it, so that the worshippers might have the least annoyance from the noise or smell of the repasts. On the eastern side the chapter house was placed, with other apartments adjacent to it, belonging to the common use of the brethren, and, as a rule, the dormitory occupied the whole upper story.

On the opposite or western side were generally the cellarer's lodgings, with the cellars and storehouses in which the necessary provisions were housed. In Cistercian monasteries the western side was usually occupied by the *domus conversorum* or lodgings of the lay brethren, with their dayrooms and workshops below and dormitory above. The cloister, with its surrounding buildings, generally stood on the south side of the church, to secure as much sunshine as possible.



A very early example of this disposition is seen in the plan of the monastery of St. Gall. Local requirements caused the cloister, in some instances, to be placed to the north of the church. This is the case at Canterbury, Gloucester, Chester and Lincoln cathedrals.

Although the covered ambulatories are essential to the completeness of a monastic cloister, a chief object of which was to enable the inmates to pass under cover from one part of the monastery to another, they were sometimes wanting. The cloister at St. Albans seems to have been deficient in ambulatories till the abbacy of Robert of Gorham, 1151–66, when the eastern walk was erected. This, as was often the case with the earliest ambulatories, was of wood, covered with a sloping roof or "penthouse." We learn from Osbern's account of the conflagration of the monastery of Christ Church, Canterbury, 1067, that a cloister with covered ways existed at that time, connecting the church, the dormitory and the refectory. An early drawing of the monastery of Canterbury shows it formed by Norman arches supported on shafts, and covered by a shed roof. A fragment of such an arcaded cloister is still found on the eastern side of the infirmary cloister. This earlier form of cloister has been generally superseded in England by a range of windows, usually unglazed but sometimes, as at Gloucester, provided with glass, lighting a vaulted ambulatory, of which the cloisters of Westminster abbey, Salisbury and Norwich are typical examples. The older design was preserved in the south, where "the cloister is never a window, but a range of small elegant pillars, sometimes single, sometimes coupled, and supporting arches of a light and elegant design" (Fergusson, *Hist. of Arch*, i, p. 610).

Examples of this type are the exquisite cloisters of St. John Lateran and St. Paul's Outside the Walls at Rome, where the coupled shafts and arches are richly ornamented with ribbons of mosaic, and those of the convent of St. Scholastica at Subiaco, all of the 13th century, and the beautiful cloisters of Le Puy-en-Velay and Arles in southern France (both 11th century) and that at Laach, where the quadrangle occupies the place of the "atrium" of the early basilicas at the west end, as at S. Clemente at Rome and S. Ambrogio at Milan. Spain also presents some magnificent cloisters of both types, of which that of the royal convent of Huelgas, near Burgos, of the arcaded form, is, according to Fergusson, "unrivalled for beauty both of detail and design." Also notable are those of Monreale and Cefalu in Sicily (12th century), where the arrangement is the same, of slender columns in pairs with capitals of elaborate foliage supporting pointed arches of great elegance of form.

The Campo Santo at Pisa is in reality a large and magnificent cloister. It consists of four ambulatories as wide and lofty as the nave of a church, erected in 1278 by Giovanni Pisano, round a cemetery composed of soil brought from Palestine by Archbishop Lanfranchi in the middle of the 12th century. The window openings are semicircular, filled with elaborate tracery in the latter half of the 15th century. The inner walls are covered with frescoes, invaluable in the history of art, by Orcagna, Simone Memmi, Buffalmacco, Benozzo Gozzoli and other early painters of the Florentine school. The ambulatories now serve as a museum of sculpture.

The great monastic establishments of Italy contain numerous important cloisters; there are frequently two or three in a single monastery—one large cloister for the general use of the monks and smaller cloisters in connection with the residence of the prior or abbot, the service portions and various other minor buildings. The cloisters at the Certosa at Pavia (15th century) are notable for their size and quaint, early Renaissance ornament. In the Certosa at Rome, now part of the Museo delle Terme, the cloister is a large arcade of pure and simple Renaissance type. Another interesting Renaissance example is that which Bramante designed for the church of S. Maria della Pace at Rome, 1504. Later

Renaissance cloisters tended more and more to become duplicates of palace courtyards.

The cloister of a religious house was the scene of a large part of the life of its inmates. It was the place of education for the younger members and of study for the elders. A canon of the Roman council of 826 enjoins the erection of a cloister as an essential portion of an ecclesiastical establishment for the better discipline and instruction of the clerks. Peter of Blois describes schools for the novices as being in the west walk, moral lectures being delivered in that next the church. At Canterbury the monks' school was in the western ambulatory, and it was there that the novices were taught at Durham (Willis, *Monastic Buildings of Canterbury*, p. 44; *Rites of Durham*, p. 71). The other alleys, especially that next the church, were devoted to the studies of the elder monks. The constitutions of Hildemar and Dunstan enact that between the church service the brethren should sit in the cloister and read theology. For this purpose small studies, known as "carrols," *i.e.*, a ring or enclosed space, were often found in the recesses of the windows. Of this arrangement there are examples at Gloucester and Chester. The use of these studies is thus described in the *Rites of Durham:* "In every wyndowe" in the north alley "were iii. pewes or carrells, where every one of the olde monkes had his carrell severally by himselfe, that when they had dyned they dyd resorte to that place of cloister, and there studyed upon their books, every one in his carrell all the afternonne unto evensong tyme. This was there exercise every daie." On the opposite wall were cupboards fúll of books for the use of the students. The cloister arrangements at Canterbury were similar. New studies were made by Prior De Estria in 1317, and Prior Selling (1472–94) glazed the south alley and constructed "the new framed contrivances, of late styled carrols" (Willis, *Mon. Buildings*, p. 45).

The cloisters were used also for recreation. The constitutions of Archbishop Lanfranc, sec. 3, permitted the brethren to converse together there at certain hours. To maintain discipline a special officer was appointed under the title of *prior claustri*. The cloister was furnished with a stone bench running along the side. It was also provided with a lavatory, usually adjacent to the refectory, but sometimes standing in the central area termed the cloister garth, as at Durham.

The cloister garth was used as a place of sepulture, as well as the surrounding alleys. The cloister was in some few instances of two stories, as at Old St. Paul's and St. Stephen's chapel, Westminster; and occasionally, as at Wells, Chichester and Hereford, had only three alleys, there being no ambulatory under the church wall.

The larger monastic establishments had more than one cloister; there was usually a second connected with the infirmary, of which there are examples at Westminster abbey and at Canterbury, and sometimes one giving access to the kitchen and other domestic offices. The cloister was not an appendage of monastic houses exclusively. It was also attached to colleges of secular canons, as at the cathedrals of Lincoln, Salisbury, Wells, Hereford and Chichester, and formerly at St. Paul's and Exeter. A cloister forms an essential part of the colleges of Eton and Winchester, and of New college and Magdalen at Oxford. These were used for religious processions and lectures, and for places of exercise for the inmates generally in wet weather, as well as for sepulture.

CLONAKILTY, urban district, County Cork., Ire., at the head of Clonakilty bay, 33 mi. S.W. of Cork by rail. Pop. (1951) 2,742. There are megaliths in the neighbourhood. Richard Boyle, first earl of Cork, granted it a charter in 1613 and it was prosperous until 1641, when it was almost destroyed in a fight between the English and Irish.

There are castles at Galley head, Dunnycove and Dunowen. The linen industry was important in the 18th century. The present trade is in brewing, agricultural produce and fishing. The harbour is obstructed, but there is a pier for large vessels at Ring 1 mi. below the town.

CLONE, a group of individual organisms usually descended by asexual reproduction from a single sexually produced individual. The term is used specifically for such animals as aphids which reproduce parthenogenetically, and of plants that are propagated by vegetative means, as cuttings. (*See* HEREDITY; PARTHENOGENESIS.) (J. M. Bl.)

CLONES, an urban district of County Monaghan, Ire., 64½ mi. S.W. by W. from Belfast by the Great Northern of Ireland railway. It is at the focus of ways from Dublin, Belfast, Londonderry, Enniskillen and Cavan. Pop. (1951) 2,455. There is a rath (encampment) in the vicinity.

Clones was the seat of an abbey founded in the 6th century by St. Tighernach (Tierney). Remains of the abbey include a nave and tower of the 12th century. There is a round tower 75 ft. high. The market place, called the Diamond, has an ancient cross and occupies the summit of the hillock on which the town stands. Lacemaking is now extinct, but the town has agricultural trade.

CLONMACNOISE, a famous early Christian centre on the River Shannon, County Offaly, Ire., 9 mi. S. of Athlone. An abbey founded 541 by St. Kieran became famous and several books of annals were compiled there; Alcuin came to be taught by Colcu at Clonmacnoise. The *Book of the Dun Cow* (written about 1100) is a copy of an older collection of romances written on the skin of a cow of St. Kieran. The ecclesiastical foundation was called the Seven Churches of Clonmacnoise and their remains still survive.

The fine west doorway of the Great church is Early; the other churches are those of Fineen, Conor, St. Kieran, Kelly, Melaghlin and Dowling. There are two round towers, O'Rourke's and McCarthy's, which is attached to Fineen's church and has a doorway at ground level, an unusual feature. There are three crosses, the great cross facing the door of the Great church. Many inscribed stones of the 9th century and later are preserved in the churches. Clonmacnoise became a bishopric and there are remains of a castle and bishop's palace (14th century); it was wasted by the English in 1552; and in 1568 the diocese was merged in that of Meaths.

CLONMEL (*Cluain meala*, or "vale of honey"), municipal borough and county town of County Tipperary, 112 mi. S.W. from Dublin, Ire., a junction on the Great Southern railway (Waterford, Limerick, Thurles), on both banks of the River Suir and on Moore and Long Islands. Pop. (1951) 10,471. It is near fine scenery in the Galtee and Knockmealdown mountains. It is at the head of barge navigation on the Suir. As a walled town (remains are still visible) it was frequently mentioned in the middle ages, but it was dismantled after capture by Oliver Cromwell (1650). Charles Bianconi (1815) made it the centre of a system of conveyance of passengers by light cars in south Ireland.

The town has a fair agricultural trade, formerly made woollen goods and is an assize town.

CLOOTS, JEAN BAPTISTE DU VAL DE GRÂCE, BARON VON (1755–1794), better known as ANACHARSIS CLOOTS, revolutionary fanatic, was born near Cleves at the castle of Gnadenthal, of a noble Prussian family of Dutch origin. His father placed him in the military academy at Berlin, but he left it at the age of 20 and traversed Europe, preaching his revolutionary philosophy as an apostle and spending his money as a man of pleasure. On the outbreak of the Revolution he went to Paris. On June 19, 1790, he appeared at the bar of the assembly at the head of 36 foreigners and, in the name of this "embassy of the human race," declared that the world adhered to the "Declaration of the Rights of Man and Citizen." After this he was known as "the orator of the human race," by which title he called himself, dropping that of baron and substituting for his baptismal names the pseudonym of Anacharsis, from the famous philosophical romance of the abbé J. J. Barthélemy. In 1792 he placed 12,000 livres at the disposal of the republic—"for the arming of 40 or 50 fighters in the sacred cause of man against tyrants."

In September he was elected a member of the convention, and he voted the king's death in the name of the human race. He was guillotined as an Hébertist on March 24, 1794.

See G. Avenel, *Anacharsis Cloots, orateur du genre humain* (1865).

CLOQUET, a city of Carlton county, Minn., U.S., on the St. Louis river, 21 mi. W. by S. of Duluth. It is served by the Chicago, Milwaukee, St. Paul and Pacific, Duluth and North-

eastern, Great Northern and Northern Pacific railways. The population in 1950 was 7,685; in 1940 was 7,304 by the federal census. The river supplies water power, and the city has large pulp and paper mills and factories making insulating materials, clothespins, matches and other articles of wood. A forest experiment station of the University of Minnesota is located there. The first mill was built in 1878, and the village was named from the French word *claquet,* representing the sound made by the mill. It was chartered as a city in 1903.

CLOSE, MAXWELL HENRY (1822–1903), Irish geologist, was born in Dublin in 1822. He was educated at Weymouth and at Trinity college, Dublin, took holy orders and held various charges in England. In 1861 he returned to Dublin and devoted himself especially to the glacial geology of Ireland. His paper, read before the Geological Society of Ireland in 1866, on the "General Glaciation of Ireland" is a masterly description of the effects of glaciation and of the evidence in favour of the action of land ice.

Later on he discussed the origin of the elevated shell-bearing gravels near Dublin, and expressed the view that they were accumulated by floating ice when the land had undergone submergence. He died in Dublin Sept. 12, 1903.

The obituary by G. A. J. Cole in *Irish Naturalist,* vol. xii (1903) contains a list of publications and portrait.

CLOSE, a closed place (Lat. *clausum,* "shut"). In English law the term is applied to land, enclosed or not, held as private property, or to any exclusive interest in land sufficient to maintain an action for trespass. In Scotland the word is used of the entry, including the common staircase, of a block of tenement houses, and in architecture of the precincts of a cathedral or abbey.

The adjective "close" (*i.e.,* closed) is found in several phrases, such as close time or close season; close prices (*see* CLOSE MARKET PRICES); close borough, one of which the rights and privileges were enjoyed by a limited class (*see* BOROUGH); close rolls and writs, royal letters, etc., addressed to particular persons, under seal. (*See* LETTERS PATENT.)

CLOSED SHOP. The closed shop, in the United States, is the oldest form of union security. It is a device for protecting the status of labour organizations. All variants of union security require union membership as a condition of employment for some or all of the workers in an establishment. Under the closed shop, only members in good standing can be hired in the first instance. In a union shop, nonmembers may be hired but must acquire membership within a specified period. Preferential hiring permits the employer to hire nonunionists only when qualified unionists are not available. Under a maintenance of membership provision, those workers who hold membership at the beginning of a collective bargaining agreement, and do not elect to resign during an "escape period," must remain in good standing for the duration of the agreement. There are numerous combinations and modifications of these basic forms.

History.—The closed shop is not a development of modern industry. Mediaeval British guilds prevented the working of nonmembers; so also did, when possible, the 18th century trade clubs. Some of the guild regulations of the 16th and 17th centuries decreed that no guild journeyman was to work with a nonmember: such principles were an integral part of mediaeval society. These tactics were continued by British trade unionism and were naturally conveyed to America. The Cordwainers' society of the city of New York in 1804, the New York Typographical society in 1809 and subsequently other unions adopted bylaws forbidding members to work for employers hiring men who did not belong to their organizations or who worked for wages lower than the union scale. The chief weapon used by employers until 1836 was the invoking of old laws declaring combinations of workmen and strikes criminal conspiracies. By about 1840 the closed-shop rule had been adopted by the majority of U.S. trade unions, which refused to work with nonunion men. These were stigmatized after 1854 as "rats" or "scabs." With the repeal or nullification of conspiracy statutes, employers formed local associations to resist the closed-shop movement.

From 1870 in the United States local trade unions gradually merged into national unions, the majority of which made the maintenance of the closed shop a vital rule. During the same period, especially in the last decade of the 19th century, there were formed national associations of employers, one of the purposes of which was to maintain the open shop. Large factories locked out union men for demanding the closed shop: the Birmingham Rolling Mill company in 1884; the Granite Manufacturers' Association of Boston in 1887; and the Carnegie Steel company in 1892. The American Federation of Labor declared in 1890 that the working of union with nonunion men was inconsistent, especially when nonunion men displaced unionists locked out or engaged in strike. From 1850 to 1898 the major part of more than a dozen court decisions held that strikes for the closed shop were criminal or tortious. These decisions had no effect upon trade-union insistence for the closed shop.

Developments of 20th Century.—The struggle over the closed-shop question reached an intense stage about 1901 when the unions insisted upon employers signing written agreements conceding the closed shop. Previously the granting of the closed shop had been based upon custom or oral negotiation. Declaring that they would not admit "union dictation in the management of business," the National Metal Trades federation and other large employers' associations aggressively campaigned to destroy the closed-shop system.

The award of the anthracite coal strike commission in the great coal strike of 1902 was of considerable moral help to manufacturers' associations; the commission granted practically every demand of the union except that for the closed shop. Encouraged by this stand, the National Association of Manufacturers in 1902 began a vigorous movement for the open shop. The Citizens' Industrial Association of America, various citizens' alliances in different cities and a number of large corporations did likewise. The American Federation of Labor reiterated that the trade-union movement stood for the strictly union shop. Union after union endorsed the closed-shop principle. The proportion of strikes for recognition of trade unions and union rules more than trebled in succeeding years. By reducing employment, the panic of 1907 weakened the trade unions and gave corresponding advantage to employers. The campaigns carried on by the manufacturers' associations also caused a decided shift in public sentiment in favour of the open shop. By 1910 this was established in many industries, notably those which had been consolidated into powerful corporations. The open shop prevailed in the south.

There were several cycles of ebb and flow in unionism after the United States entered World War I in 1917. Certain main tendencies persisted, however. Union membership increased greatly standing at 2,750,000 in 1916 and 14,500,000 in 1952. Collective bargaining was established in many industries previously of nonunion or open-shop character. There was widespread improvement of industrial relations as union and management became accommodated to each other and accumulated bargaining experience. The scope of collective agreements expanded steadily to include not only wage rates and hours of work but also seniority provisions; paid vacations and holidays, retirement plans, sickness, hospital and accident insurance; and numerous other matters. Despite these changes, the union security issue remained an active one and occasioned considerable industrial conflict.

"Union security" was probably the most frequent problem faced by the U.S. government in handling unresolved labour disputes during World War II. The National Defense Mediation board (1941) collapsed when members of the Congress of Industrial Organizations withdrew because of the board's refusal to recommend a union shop in "captive" coal mines. Its successor, the National War Labor board (1942–45), developed the maintenance-of-membership formula as a compromise measure, and utilized the formula in thousands of dispute cases. By 1945, almost 30% of workers under union agreement were covered by maintenance-of-membership clauses. Some 45% were employed in closed or union shops, and 3% under preferential hiring arrangements. The remaining 27% worked in establishments where the union was recognized as exclusive bargaining agent but did not enjoy formal union security protection.

In the Taft-Hartley act of 1947, the U.S. congress undertook for the first time to regulate the union security agreement in private industry. The closed shop was declared illegal. Labour organizations were prohibited from negotiating union shop agreements unless authorized, in a secret ballot, by a majority of workers in the bargaining units. These restrictions, designed to implement the right to work and to protect rank-and-file employees from the unions, did not have the intended effect. During the first four years of the Taft-Hartley act, 97.1% of all union-shop elections were won by the unions; 84.8% of eligible employees voted, and 91.4% of all voters cast affirmative ballots. Moreover, the proscription of closed shops was widely circumvented by various methods, particularly in the building construction, printing and maritime industries. By 1950, the proportion of unionized employees in closed, union or preferential shops had risen to 58%; and in 1951–52 union shop provisions were adopted in the rubber and steel industries and part of the railroad industry. The Wage Stabilization board's recommendation in 1952 that some type of union shop be established in the steel industry was highly controversial, however, and induced congress to prohibit the board from handling union-management disputes. (*See* also STRIKES AND LOCKOUTS; TRADE [LABOUR] UNIONS.)

CLOSE MARKET PRICES. Proper comprehension of the meaning of "close market prices" and their importance in a free economy requires an understanding of what market prices actually are and an examination of the double pricing standard that prevails in securities markets. Essentially, market prices are those figures at which public buyers and sellers are ready, willing and able to trade money for securities or vice versa. The double pricing standard refers to (1) the particular maximum price which buyers will pay for a particular share and (2) the particular minimum price which sellers expect to receive in return for a particular share. The closeness of market prices describes the proximity of either end of the double standard to the other—the narrow difference between a seller's minimum figure and a buyer's maximum price. This is the auction system, which prevails in the world's great securities markets such as the London, New York and American Stock exchanges. On these and other auction markets, keen competition between buyers and sellers and the law of supply and demand ultimately decide final sales. These markets, with their national and international communication facilities including thousands of member firm main and branch offices which bring public orders to market, huge stock ticker systems, and teleregister, teletype, telephone, cable and radio networks, concentrate public orders on their respective trading floors and make close markets which effect fair prices.

Bid and Offer.—The public market for a particular stock issue is naturally divided between buyers and sellers. Among the potential buyers there is a wide range of judgment, depending upon individual knowledge of true worth, as to what they would be willing to spend for a single share of, for example, ABC common stock. The range of individual judgment may run from as low as 5 and move upward fractionally to 9. In auction markets, the highest proposal to buy becomes the bid. In this case the bid is 9. Another range of judgment is expressed by sellers in amounts of money that they want in return for a single share of ABC common stock. The prices may range from a high of 14 and move downward fractionally to 10. Under the auction principle, the lowest proposal to sell becomes the offer. In this case the offer is 10. We now have the double standard, the quotation, the bid and offer or the market, as it is commonly called. The concentration of public buy and sell orders at a single, focal point, the trading floor of the securities market trading ABC common shares, has resulted in a close market with a one point spread between the bid and offer. This price will be quoted on the trading floor, posted in brokerage company board rooms, reported over the communications systems and will appear in the public press. It does not mean that the bid or the offer will prevail in a sale, but that an order "at the market" will be executed at or within 9 or 10 depending upon supply and demand. (J. J. SN.)

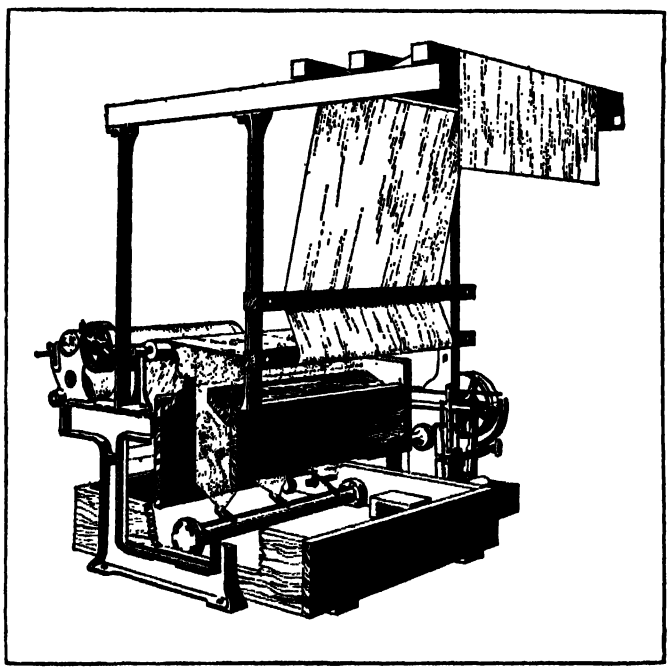
CLOSURE, the parliamentary term for the closing of debate according to a certain rule, even when certain members are anxious to continue the debate. In the U.S. "cloture" is a common spelling. (*See* PARLIAMENT: *Parliamentary Procedure.*)

CLOT, ANTOINE BARTHÉLEMY (1793–1868), French physician, known as CLOT BEY, was born at Grenoble on Nov. 7, 1793, and graduated in medicine and surgery at Montpellier. After practising for a time at Marseilles he was made chief surgeon to Mohammed Ali, viceroy of Egypt. At Abuzabel, near Cairo, he founded a hospital and schools for all branches of medical instruction, as well as for the study of the French language; and instituted the study of anatomy by means of dissection. In 1836 he was appointed head of the medical administration of the country. In 1849 he returned to Marseilles, though he revisited Egypt in 1856. He died at Marseilles on Aug. 28, 1868.

CLOTAIRE (CHLOTHACHAR), name of four Frankish kings.

CLOTAIRE I. (d. 561) was one of the four sons of Clovis. On the death of his father in 511 he received as his share of the kingdom the town of Soissons, which he made his capital, the cities of Laon, Noyon, Cambrai and Maastricht, and the lower course of the Meuse. But he was very ambitious, and sought to extend his domain. He was the chief instigator of the murder of his brother Chlodomer's children in 524, and his share of the spoils consisted of the cities of Tours and Poitiers. He took part in the various expeditions against Burgundy, and after the destruction of that kingdom in 534 obtained Grenoble, Die and some of the neighbouring cities. When Provence was ceded to the Franks by the Ostrogoths, he received the cities of Orange, Carpentras and Gap. In 531 he marched against the Thuringi with his brother Theuderich (Thierry) I., and in 542 with his brother Childebert against the Visigoths of Spain. On the death of his great-nephew Theodebald in 555, Clotaire annexed his territories; and on Childebert's death in 558 he became king of all Gaul. He also ruled over the greater part of Germany, made expeditions into Saxony, and for some time exacted from the Saxons an annual tribute of 500 cows. The end of his reign was troubled by internal dissensions, his son Chram rising against him on several occasions. Following Chram into Brittany, where the rebel had taken refuge, Clotaire shut him up with his wife and children in a cottage, to which he set fire. Overwhelmed with remorse, he went to Tours to implore forgiveness at the tomb of St. Martin, and died shortly afterwards.

CLOTAIRE II. (d. 629) was the son of Chilperic I. On the assassination of his father in 584 he was still in his cradle. He was, however, recognized as king, thanks to the devotion of his mother Fredegond and the protection of his uncle Gontran, king of Burgundy. It was not until after the death of his cousin Childebert II. in 595 that Clotaire took any active part in affairs. He then endeavoured to enlarge his estates at the expense of Childebert's sons, Theodebert, king of Austrasia, and Theuderich II., king of Burgundy; but after gaining a victory at Laffaux (597), he was defeated at Dormelles (600), and lost part of his kingdom. After the war between Theodebert and Theuderich and their death, the nobles of Austrasia and Burgundy appealed to Clotaire who, after putting Brunhilda to death, became master of the whole of the Frankish kingdom (613). He was obliged, however, to make great concessions to the aristocracy to whom he owed his victory. By the constitution of Oct. 18, 614, he gave legal force to canons which had been voted some days previously by a council convened at Paris, but not without attempting to modify them by numerous restrictions. He extended the competence of the ecclesiastical tribunals, suppressed unjust taxes and undertook to select the counts from the districts they had to administer. In 623 he made his son Dagobert king of the Austrasians, and gradually



subdued all the provinces that had formerly belonged to Childebert II. He also guaranteed a certain measure of independence to the nobles of Burgundy, giving them the option of having a special mayor of the palace, or of dispensing with that officer. These concessions procured him a reign of comparative tranquillity. He died on Oct. 18, 629, and was buried at Paris in the church of St. Vincent, afterwards known as St. Germain des Prés.

CLOTAIRE III. (652–673) was a son of king Clovis II. In 657 he became the nominal ruler of the three Frankish kingdoms, but was deprived of Austrasia in 663, retaining Neustria and Burgundy until his death.

CLOTAIRE IV. (d. 719) was king of Austrasia from 717 to 719. (C. PF.)

CLOTH, any material woven of wool or hair, cotton, flax or vegetable fibre. In commercial usage, the word is particularly applied to a fabric made of wool. The word is Teutonic, though it does not appear in all the branches of the language. It appears in German as *Kleid* (*Kliedung,* clothing), and in Dutch as *kleed.* The ultimate origin is unknown; it may be connected with the root *kli*—meaning to stick, cling to, which appears in "clay," "cleave" and other words. The original meaning would be either that which clings to the body, or that which is pressed or "felted" together. The regular plural of "cloth" was "clothes," which is now confined in meaning to articles of clothing, garments, in which sense the singular "cloth" is not now used. For that word, in its modern sense of material, the plural "cloths" is used. This form dates from the beginning of the 17th century, but the distinction in meaning between "cloths" and "clothes" is a 19th century one. A curious employment of the word is in the clerical profession, its members often being spoken of as belonging "to the cloth." (*See* WOOL; COTTON AND THE COTTON INDUSTRY; etc.)

CLOTH FINISHING. In this article, the subject of finishing is treated under the two headings (1) Cotton and (2) Wool.

COTTON

The finishing of cotton fabrics was originally the final operation performed on the fabrics to make them ready for sale. In its modern significance, finishing comprises a large and diverse range of processes intended to produce in the fabric a desired appearance or feel; and the machines required for this purpose are correspondingly numerous and varied; finishing operations require plant for, to name some of the important processes, shearing, stretching, drying, damping, pressing, embossing, impregnating, covering and raising cotton cloths.

Classification of finishes in relation to the many different kinds of cotton fabrics is difficult, because many of the processes are applicable to a wide range of cloths. They may be considered under the following headings:—Grey goods, *i.e.,* cloth direct from

BY COURTESY OF MATHER AND PLATT, LTD.

FIG. 2.—THREE-BOWL FINISHING CALENDER ARRANGED TO GIVE A BRIGHT FINISH ON BOTH SIDES OR A GLAZED SURFACE ON ONE SIDE ONLY

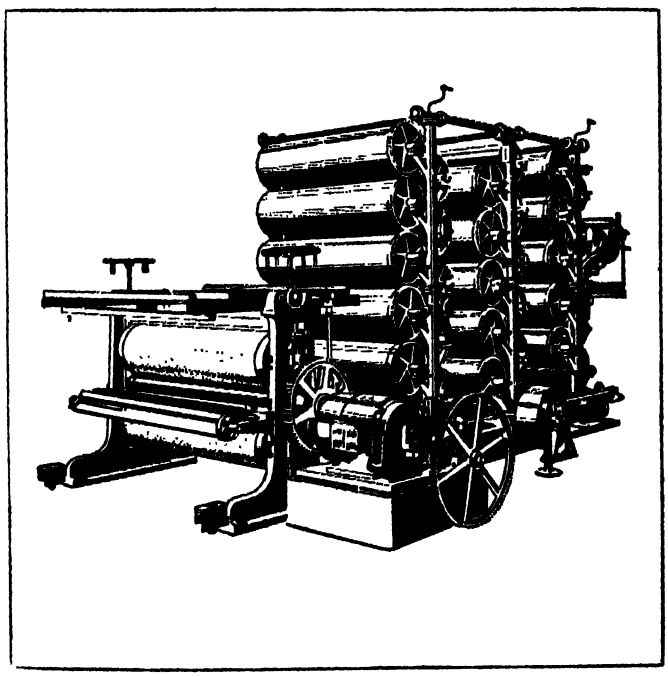
the loom; white goods, *i.e.,* cloth which has undergone a bleaching process; plain dyed goods—colours and black; printed goods; raised goods.

The greater number of processes of finishing cotton goods are empirical in character; the underlying physical and chemical changes are not fully understood. A finish produced in one works may be impossible to reproduce in another works, although the same kind of plant and mixings are being used. Even in the same works, two apparently identical machines will give appreciably different results. This is not to say that finishing is a matter of chance; there are very wide differences between the various classes of finish which differences are definable in terms of plant and mixing.

The following gives some idea of the finishing machines used for the different qualities set out above:—

Grey Goods.—These may be finished pure, *i.e.,* without any additional size or stiffening. After passing through a shearing machine or a combined moting and shearing machine, the cloth may be conditioned in a damping machine of the brush type or the spray type (fig. 1) and afterwards calendered in a suitable calender, such as the three-bowl swissing calender (fig. 2) or a five or seven bowl calender arranged to give a bright finish on both sides of the cloth, or a friction calender giving a glazed surface on one side only. Grey goods which are stiffened before being calendered are passed through a range comprising a mangle and cylinder drying machine (fig. 3). The mangle may have two or three bowls, and the drying set may be horizontal or vertical.

Coloured woven goods, *i.e.,* woven from grey bleached and dyed yarns, may be treated in a manner similar to the grey, making use of the same kind of machinery. Both grey and coloured woven goods may be run through the clip-stretching machine with the object of recovering width, or straightening weft, or improving the feel by breaking down the hardness produced in an earlier process, or lifting the figure of the original weave.



White Goods.—Here there are a very wide range of finishes requiring very extensive plant; for example

(a) Pure finish (without stiffening); these may, or may not be calendered or beetled.
(b) Finishes requiring impregnation of the cloth with the stiffening mixture.
(c) "Back-filling," that is, the stiffening is applied to the back of the cloth only.

White goods are generally passed through a water-mangle with the object of improving the appearance of the cloth, closing up the threads after the bleaching process, and preparing it for the filling mixture. After mangling, the cloth is dried on an ordinary cylinder machine (fig. 4) or for twills or figured goods, additional rollers or winces are added so that the face side does not come in contact with the cylinders. White goods are usually starched in conjunction with the drying machines, as for grey, coloured woven, dyed and printed goods. Various types of starch mangles are used for this purpose; the two-bowl mangle; the two-bowl friction calender by which the filling can be forced into the cloth; the back-filling mangle.

After starching or filling, the cloth is dried over a cylinder drying machine, back-filled goods being dried over machines with the modification referred to which permits of only one side of the cloth coming in contact with the metal. Or instead of cylinder-drying, the cloth may be dried on a hot-air stentering range. The starch mangle shewn in this illustration is not usual in this combination in white-finishing. By this method, any lost width may be recovered, the feel of the cloth is better, and an elastic finish may be produced by the jigging motion of the stenter, and any weft-distortion may be corrected.

The further processes may involve the use of the damping machine (fig. 1) and various calenders similar to those given for grey and coloured finishing and possibly the beetling machine.

FIG. 3.—HEAVY FINISHING RANGE WITH VERTICAL DRYING MACHINE

Plain Dyed Goods.—These also require a great variety of finishes, but the range of machines used is not so great as in the case of white goods, for instance, back-filling and friction starching is rarely employed with dyed goods. Three and four bowl water mangles are employed and a drying from these machines is generally effected on drying cylinders. The stiffening of dyed goods is carried out on a two-bowl mangle and cylinder drying machine, or preferably on a hot-air stentering range, for example, mangle cyliners and 90ft. stenter with hot-air drying. Damping machines, stretching machines, breaking machines, calenders from three to seven bowls with and without friction may be required, for certain finishes; for producing window blinds beetles are required; Schreiner calenders for silky finishes and embossing calenders for book cloths, etc.

Printed Goods.—These are finished on similar machines to those used for dyed goods. For ordinary stiffening or starching a range comprising a two-bowl starch mangle, followed by a

BY COURTESY OF MATHER AND PLATT, LTD

FIG. 4.—VERTICAL DRYING MACHINE ON THREE PAIRS OF UPRIGHTS; FOR DRYING CLOTH AFTER MANGLING

cylinder drying machine is employed, or a hot-air stentering range consisting of a two-bowl mangle, six-cylinder drying machine and 90ft. stenter with hot-air drying. For muslins, voiles and goods requiring an elastic or batiste finish, the latter method is indispensable.

Another method of stiffening known as back starching, differs from the ordinary method, in that the starch paste is applied to the back or unprinted side of the fabric by means of a brass roller partly immersed in the starch box. The drying of back starched cloth is performed by passing the cloth over the drying cylinders of large diameter, say, from 5 to 7 feet, arranged in such a manner that the starched side does not come in contact with the heated cylinders. An ordinary drying machine can be employed, but in this case, precautions have to be taken by cooling the first cylinders to prevent the starched side adhering to the cylinders. A back starcher or universal starcher can be used in conjunction with a hot-air stenter instead of the usual cylinder drying machine. The additional machines which may be required for finishing printed goods are similar to those already mentioned, and include clip-stretchers, swissing and friction calenders, Schreiner calenders, beetles, as for dyed goods.

Raised Goods.—In this class are included those cloths which are raised on one or both sides, such as flannelettes. Similar machines to those employed for dyed goods are used for the actual finishing, the stiffening being carried out on a mangle and drying machine, or hot-air stentering range. The conditioning clip stenter is especially useful.

Calenders are not usual, brushing and lustring machines being used instead.

WOOLLEN GOODS

The finishing of woollen goods requires in general plant and processes entirely different from those described in connection with cotton. The methods employed naturally vary with the nature of the fabric: for example, worsted fabrics (woven from yarns produced from the longest staple fibre, and containing the

maximum of parallelism between the fibres) require in general a "clearer" finish than woollen fabrics woven from yarns composed of interlaced fibres of all lengths, which lend themselves to milling and raising. In the former case, the characteristics of the fabric structure dependent upon the nature of the weave are largely retained, and even developed, while in the latter case the thready appearance of the loom state fabric often gives way to a felted effect in which the individual warp and weft threads are no longer discernible, the change being usually accompanied by an increase in density and a corresponding decrease in width and length of the fabric. In wool goods, "finishing" covers all the processes undergone by the fabric after leaving the loom. There are certain preliminary operations to which the piece is subjected before the finishing process proper, which are intended to correct weaving faults and yarn defects. The pieces are "perched" over a bar or roller usually in a north light and examined by the eye and by hand feeling. "Knotting" consists in removing knots from warp or weft by first drawing these through to the back of the cloth, after which they are cut away. "Mending" or "darning" is the process of correcting defects such as holes and missing yarn (short ends and picks) by inserting new threads correctly interlaced in accordance with the weave structure. The finishing processes proper divide themselves into the two groups of wet and dry operations.

Wet Operations.—These include crabbing, scouring, milling, tentering and carbonizing.

Crabbing. The object of this process is to "set" the fabric, *i.e.*, to obviate the risk of distortion in subsequent processes. The piece is tightly wound in a stretched condition over a perforated roller, which allows steam or hot water or both to be forced through the piece. The combined effect of moisture and heat is to render the wool fibre plastic, and in this condition the internal strains in the fabric which might produce cockling in a subsequent wet process are released, and on cooling the fabric assumes a more or less permanent "set."

Scouring. This process is intended to remove grease and oil and mechanically adhering dirt from the wool goods. The detergents used are either soaps or alkalis depending upon the amount and character of the oil present in the wool. Some fabrics are conveniently scoured in the rope-form, while others—*e.g.*, those liable to crease, are best scoured in the open width.

Milling. This process makes use of a special property of the wove fibre of "felting." The woollen cloth is impregnated with a solution of soap (more rarely of acid) and subjected to pressure between rotating rollers in the milling machine, or by the action of fallers in the stilling stocks. As a result of this action, the fibres become matted or felted if the milling is carried far enough, the warp and weft threads appear to lose their identity, and the woven structure of the cloth is entirely hidden. The cloth often gains strength as a result of milling, while the density is increased at the expense of the width and length, the whole fabric being rendered more consistent.

Tentering. After the scouring process, the pieces may be dried by first removing the excess of water by hydro-extracting or by passing through the wringer; and afterward subjecting to the drying action of warm air while stretched out between the lists or edges. In addition to drying the pieces, this operation straightens and "sets" the cloth.

Carbonizing. Some kinds of wool fabrics, *e.g.*, velours, may be produced from low quality wools containing vegetable matter. This impurity may be removed by soaking the fabric after scouring in a solution of sulphuric or other acid, drying, and raising to a temperature of about 100° C., when the vegetable matter is disintegrated and may be removed by a slight beating and air draught.

Dry Operations.—These include raising, cutting, napping, blowing, brushing, steaming and pressing.

Cutting. This operation formerly performed by hand with large shears is now carried out on a suitable machine. It consists in removing the pile of the fabric beyond a certain length, this length varying greatly with the class of fabric. For example, worsted cloths are cut close to the surface in order to enhance the effects of weave and colour. Woollen fabrics only receive as a rule a cutting sufficient to level up the projecting fibres.

Blowing consists in subjecting the pieces wound in the open width on a perforated beam to the action of steam. There is some resemblance to the crabbing process already described, and the object is again to "set" the fabric permanently, though other advantages are also usually obtained, such as increase in the lustre of the fabric.

Steaming differs from the blowing process in that the fabric is drawn from one roller to another over a box with perforated top from which steam issues. The object is to raise the fibre somewhat, and thus destroy any glaze, and to soften the feel or handle as a result of the conditioning effect of the steam, *i.e.*, by the absorption of moisture.

Raising. This is a mechanical operation in which fibres are lifted from the yarns in the cloth, or from the surface to produce a pile or nap. The raising process was formerly effected by the use of teazles (Dipsacus fullonum) applied by hand; and teazles are still used, mounted on cylinders and operated by power. In addition, cord-wire raising is largely practised; in this form a number of raising rollers are covered with cord clothing, and revolve against the cloth which is made to pass over them by an independent motion.

Pressing is an important operation in the finishing of wool goods; it may be carried out with the object of smoothing the surface of the fibre and imparting an appearance of uniformity, or by prolonged treatment the lustre of the fabric may be greatly increased. The fabric, charged with a sufficient amount of moisture, is subjected to the combined action of (usually) heat and hydraulic pressure. Three different systems are used, (1) the vertical hydraulic press, (2) the intermittent hydraulic press, (3) the rotary press.

Shrinking. The tendency of wool garments to contract in wear is well known. The object of the shrinking process is to bring out this contraction in dimensions before the garment is made up. It is usually effected by thoroughly wetting the material, and redyeing it at a low temperature, after which a mild pressing treatment is applied to remove creases, etc. There are many names for varieties of this "shrunk finish"; perhaps the best known being "the London-shrunk finish."

Not all the above processes are utilized in finishing a particular class of wool fabric. Worsted cloths in the main undergo the series of operations known as the clear-cut finish. These cloths include fancy vestings and suitings, striped trouserings, costume cloths and dress fabrics, fancy worsteds, etc. A finishing routine for the latter involves knotting and mending, crabbing, scouring, tentering, brushing and steaming, cutting, blowing and pressing.

(F. Sc.)

CLOTHIER, a manufacturer of cloth, or a dealer who sells either the cloth or made-up clothing. In the United States the word formerly applied only to those who dressed or fulled cloth during the process of manufacture, but now it is used in the general sense, as above.

CLOTHIERS, WHOLESALE. The term wholesale clothiers is applied to the makers and distributors of ready-to-wear or machine-made woollen and other types of outer clothing for men and women, comprising suits and overcoats for men, costumes, dresses, skirts, and coats for women. The industry forms the more important of the two divisions—wholesale and made-to-order—of the tailoring, or clothing trades.

The name "clothier" signified in the days of handloom weaving, the master clothmaker or producer, but with the advent of the power loom that designation gradually became changed to "manufacturer," prefixed generally with a qualifying name indicative of the class of fabric made, such as "cloth," "woollen," or "worsted."

Some makers, however, prefer to style themselves manufacturing clothiers. In America, the cloth dresser (finisher), or fuller was formerly termed a clothier.

CLOTHING MANUFACTURE. The application of the sewing machine to tailoring made the production of ready-made clothing possible in bulk. The early demand for ready-made clothing may be traced to the older seaport towns, where such clothing was often required at short notice by persons returning from long voyages. The foundations of the wholesale clothing industry, however, may be said to rest first, on the invention of the sewing machine; and second, upon the introduction of cheap (shoddy) cloth made from pulled-up rags, from which material machine-made clothing, produced in bulk, was originally made. The use of shoddy has practically disappeared, however, and the finest grades of cloth are quite generally used by the best manufacturers of ready-made clothing, who are also in a position to employ highly qualified designers.

Thimmonier's Sewing Machine.—Ready-made clothing was first made in Paris by a tailor named Thimmonier, who invented the first sewing machine in 1830, and applied it with considerable success to the production of army clothing until 1841, when his factory was destroyed during a machinery riot. Thimmonier afterward went to England with an improved machine which he patented in 1848. This, however, met with no success, and it was not until 1851, when the American invention of Isaac Merritt Singer was introduced into England, that the industrial potentialities of the sewing machine were realized.

The quicker output obtained by mechanical sewing necessitated an increase in the speed of pattern cutting, and 1860 saw the invention of the cloth-cutting band knife (based on the principle of the band saw), which solved the problem of supplying material to keep pace with the work of the sewing machine. This machine was made in Leeds by Greenwood and Batley at the suggestion of John Barran, a native of London who had settled in Leeds some years previously, where he had commenced the wholesale clothing industry in 1855. The modern machine has a knife velocity of 7,000 ft. per minute, and can cut 50 thicknesses of cloth at once. A more modern style of machine still is a portable knife cutter worked by electricity.

Other inventions, mostly in connection with sewing, followed in rapid succession; and sewing by hand for joining most parts of a garment was almost entirely superseded by machines devised for such special purposes as felling (*i.e.*, turning over the edges of the cloth and then sewing in order to prevent fraying), sleeving, buttonhole making and button stitching. A machine for marking the outlines of the patterns to prepare them for cutting, and machines for pressing assisted further to reduce handwork to a minimum; and the transition from operating the sewing machines by hand or foot to power driving contributed to greatly increased output and cheaper production.

Division of Labour.—The modern factory system is highly sectionalized, and its production and output depend upon an extraordinary degree of subdivision of labour; so much so, that a coat, in making, may pass through the hands of as many as 50 persons. Subdivision of labour reduces the cost of production by causing the simpler processes to be effected by the unskilled labour of young persons, and utilizing skilled labour only for the more complicated work.

The system originates with the designing and production of the patterns in the various standard sizes by the head pattern or stock cutter, who is responsible for keeping in touch with movements in fashion and style. The separate paper pieces comprising a pattern for a garment or suit are then formed into what is termed a "lay" by fitting them as closely together as possible (interlocking them after the manner of a jigsaw puzzle), so that in cutting out the cloth there will be a minimum of waste; the operation being termed "lay-getting." The outlines of the lay are chalked on a large piece of tough paper or linen corresponding in width to the cloth, and then these are perforated by a machine called a "process-marker," thus forming the pattern or lay from which the garments are cut in bulk. To prepare the cloth for mechanical cutting, it is automatically folded in the number of lengths required by the "laying-up" machine; the lay is placed on the top fold, and specially prepared powdered chalk is rubbed through the perforations to indicate the lines to be followed by the knife.

After cutting, the pieces for each individual garment are sorted out and numbered, tied into bundles with their necessary trimmings, which have been prepared in a similar manner to that just described, and passed forward to the factory for making up. There, the various parts are sewn and gradually assembled into the complete garment—this being a combination of hand and machine work by trimmers, finishers, machinists (who work the specialized sewing machines) and pressers.

The industry was built up in Great Britain very largely by the exploitation of alien Jewish labour, and in fact, the origin of the subdivisional system of work was the outcome of the necessity for finding employment for the great influx of Russian Jews to London. These unfortunate people usually carried on their occupation at home, and by reason of their poverty and consequent low standard of living worked for very low rates of payment. This quickly resulted in the "sweated labour" conditions exposed by Charles Kingsley and other social reformers. In 1909, when the first Trade Board act was passed, ready-made and wholesale bespoke tailoring was classed among the four industries having "rates of wages exceptionally low as compared with those in other employments." The Tailoring Trade board was established under this act in the following year with powers to determine the minimum rates of wages in all branches of the tailoring trades, and in 1920 two separate boards were constituted—one to deal with the ready-made and wholesale section, and the other to control the retail section of the industry.

Location of Industry.—Though London was the original home of the British ready-made clothing trade, Leeds is now the chief seat of the industry, and wholesale clothing forms the leading trade in the city. There is a difference, too, in the conduct of the industry in the two centres; in Leeds it is almost entirely confined to work in the factory; in London, outworking persists to a large extent. Leeds was the first provincial town (in 1855) to engage in the industry, and no doubt owes its present leading position largely to its advantageous geographical situation in the centre of the West Riding of Yorkshire woollen and worsted cloth manufacturing area, which supplies it with all classes of fabrics from the lowest to the highest in quality. The manufacture of clothing is also carried on in the Huddersfield and Hebden Bridge districts, Liverpool and Manchester, Bristol, Colchester, and Leicester; and in Scotland, Glasgow is an important centre.

It may be noted that though ready-made clothing was identified formerly with inferior materials only, this is no longer the case, and there is now a large and increasing demand for ready-for-service garments of high class workmanship, made of the finest quality materials.

With regard to markets, it is generally considered that about two-thirds of the yearly British output is absorbed at home, and the remainder goes principally to the British colonies, though the United States is a considerable customer for the best class of British goods in spite of its own high standing in the industry.

(A. Y.)

United States.—Clothing manufacture in the United States has passed out of the hands of the merchant tailor and is conducted in modern plants equipped with labour-saving machinery. The United States is the home of ready-made clothing. It has been estimated that between 80% and 90% of the men's clothing made in the United States is of the ready-to-wear type. Half of this clothing is produced in the centres of population. As a result of the fact that people are buying cheaper clothing, cotton and other fabrics are being used in great amount.

In New York city, the most important clothing market, the greater part of the clothing is produced under the contract system. The manufacturer cuts up the cloth into the various patterns he desires and this cloth is sent to a contractor for fabrication into garments. This system partly accounts for the large number of clothing firms in New York city, for it enables a person to enter the business with comparatively small capital. In the other clothing centres most of the clothing manufacturers maintain their

own factories.

The success of mass production in the clothing industry in the United States that has developed since the 20th century began, rests upon (1) scientific pattern construction; (2) highly efficient labour-saving machinery; (3) effective factory arrangement; (4) high division of labour; (5) economies effected in the purchase and fabrication of materials on a large scale, and (6) standardization of styles. The industry did not make any great progress until scientific investigations of average proportions of the human body yielded sufficient information on which to base the present art of clothing designing. Experience has disclosed that normal proportions and variations therefrom are fairly constant in any group of 100 men. and consequently, clothing manufacturers make their garments in assortments complying with such experience. A retail store stocking 1,000 suits might, for example, have the following assortment: 54.3% regular; 31.3% short; 4.7% long; 5.6% stout; 4.1% short stout. The sizes would range from 35 to 50 (chest) with 37, 38, 39, 40, 42, and 44 making the bulk. All stores do not carry, nor do all factories make assortments as complete as above. However, the more complete the range of sizes, the less alterations, or busheling, must be made. These busheling operations are standardized, and because of the high development of the art of making ready-to-wear clothing in the United States, changes are usually slight.

In making a new model sport coat or overcoat, the designer visualizes the style he wishes to create and drafts a pattern, usually size 36 or 38. This pattern is used to derive a complete set of patterns for all required sizes, including regulars, shorts, longs, stouts, etc. The work of translating the basic pattern into other sizes is called pattern grading. In many U.S. factories the designer not only designs the models, but he also supervises the general production of the garment in the factory. Many manufacturers do not have designers and they, as well as many designers themselves, are often guilty of pirating competitors' patterns. Certain pattern houses supply patterns to the manufacturer without need of either pirating or a designer.

There are two methods of shrinking or sponging cloth in use. London or cold-water shrinking is the best and most expensive. Steam or machine shrinking is cheapest and most widely used.

In processing, the cloth is first shrunk and dried. It is then laid out on cutting tables in lays from a few thicknesses of cloth to as high as 50 or 60 in the case of work clothing; modern machines do this at high speed. The cardboard, fibreboard, or brass bound patterns are laid on the cloth in such a manner as to conserve every possible inch of cloth. After the outlines of the patterns are chalked on the top layer of the lay by a marker the outlines are cut by electric cutting machines. These machines are of two types; the one having a revolving disk cutter and the other having a vertical blade moving up and down; automatic knife sharpeners can be obtained. Some manufacturers still cut by hand knife, others by powerful dies.

Most cutting rooms are located on the top floor of the factory so that the cloth after cutting can pass through the assembly departments to the stock room by means of gravity or other conveyors. There are several systems of production; the bundle, the modified bundle, and the straight line. Each has its strengths and weaknesses. Newest is the straight-line system which applies the automobile assembly line theory of production. This is used particularly on pants and shirts. The garment is started at one end and handed on down the line, each operator performs his or her one special operation and it comes from the line as a complete unit. In this way lost motion is minimized and a high efficiency is maintained. Different types of straight lines are used—some are "Y" shaped, others are "V" shaped. Regardless of the system of production used, modern factories are highly departmentalized and division of labour is carried out to a high degree. Each operator performs but one task on a garment, thereby gaining unusual proficiency. In the making of some pockets, for example, there are 13 different operations, each one of which is performed by a single individual. One hundred persons may work on a sport coat. Not only does an operator do more work under this system, but because of the skill he develops, he does better work. This high division of labour also permits the use of workers possessing ordinary intelligence. A large percentage of the clothing factories in the United States operate on a piecework basis; *i.e.*, a unit price is fixed for each operation on a garment. Some factories use a task system, which approximates a piecework system. Still others use a set system, which is a modified form of subcontracting to groups of workers.

Much labour-saving machinery for the clothing industry has been perfected in the United States, by means of which the various operations are speeded up and the unit costs reduced. Dozens of improved types of sewing machines have been introduced which are instrumental in reducing costs. Two-needle and four-needle machines are common. The speed of some of these new machines is amazing: literally thousands of stitches per minute. The late models of buttonhole machines cut the cloth, sew and tack the buttonhole in a fraction of a minute. Even buttons are sewed on by machine. Safety tables keep all movable parts of the machines, except the needles, enclosed. Needles are protected by needle guards in many plants. New blind-stitch machines which render the stitching invisible and are adaptable to almost all types and weights of fabrics have been perfected. There is also a machine that simulates exactly a hand stitch. One of the outstanding developments in labour-saving machinery is the steam pressing machine. The machine in use is made in a variety of models having bucks shaped to fit various parts of the garment; it has materially lowered clothing pressing costs. An automatic pressing machine used more extensively outside the United States, though made there, requires only finger control. There are many other automatic compressed air machines for varied operations; especially for shirts. (C. Le.; H. Sim.)

CLOTILDA, SAINT (d. 544), daughter of the Burgundian king Chilperic, and wife of Clovis, king of the Franks. On the death of Gundioc, king of the Burgundians, in 473, his sons Gundobald, Godegesil and Chilperic divided his heritage. At Lyons an epitaph has been discovered of a Burgundian queen who died in 506 and was most probably the mother of Clotilda. Clotilda was brought up in the orthodox faith. Her uncle Gundobald was asked for her hand in marriage by the Frankish king Clovis, who had just conquered northern Gaul, and the marriage was celebrated about 493. On this event many romantic stories, all more or less embroidered, are to be found in the works of Gregory of Tours and the chronicler Fredegarius, and in the *Liber historiae Francorum*. Clotilda did not rest until her husband had abjured paganism and embraced the orthodox Christian faith (496). With him she built at Paris the church of the Holy Apostles, afterward known as Ste. Geneviève. After the death of Clovis in 511 she retired to the abbey of St. Martin at Tours. In 523 she incited her sons against her uncle Gundobald and provoked the Burgundian war. In the following year she tried in vain to protect the rights of her grandsons, the children of Clodomer, against the claims of her sons Childebert I and Clotaire I, and was equally unsuccessful in her efforts to prevent the civil discords between her children. She died in 544, and was buried at her husband's side in the church of the Holy Apostles.

There is a mediocre *Life* in *Mon. Germ. Hist.: Script. rer. Merov.*, vol. ii. *See* also G. Kurth, *Sainte Clotilde*, 2nd ed. (1897). (C. Pf.)

CLOUD, an aggregation of minute water droplets or ice particles drifting in the air at some height above the earth.

CLASSIFICATION

Although it is reasonable to suppose that the shapes and general appearance of clouds must have been a matter of interest and speculation from earliest times, no lasting contribution to the development of a scientific cloud classification was made until 1803, when Luke Howard published his classical paper entitled "On the Modifications of Clouds." The Latin terms which Howard adopted were applied with such excellent judgment that his system later became the internationally accepted basis of cloud classification.

For more than 50 years following the appearance of Howard's treatise little progress in the study of clouds was achieved. It was not until 1874, the year of the first International Meteorological congress, that important new efforts were initiated in this field. During the succeeding 20 years constructive proposals were advanced in many countries by a large number of workers whose combined efforts led in 1896 to publication of the *International Cloud Atlas*.

During the period of World War I and the years immediately following, interest in cloud forms and their prognostic significance was further stimulated by the development of aviation, and the preparation of a new and much more extensive cloud atlas was undertaken. The result was the *International Atlas of Clouds and States of the Sky* (Paris, 1932), which specifies that clouds are divided into four families, as follows: (1) high clouds, (2) middle clouds, (3) low clouds and (4) clouds with vertical development. Each family is divided into genera, of which there are ten in all. Most of the genera are subdivided into species, while species in turn are subdivided into varieties. The atlas lists 20 species

STEPS IN THE HAND-TAILORING OF MEN'S CLOTHING

1. Cutting the cloth by hand, one garment at a time, along lines marked with chalk
2. Stitching the padding of a coat front
3. Basting a sack coat. So many thicknesses of material go into a garment of this type that careful basting is necessary to assure that the final stitching anchors each piece firmly in its proper place
4. Hand-stitching the interlining of a coat lapel
5. Making a buttonhole by hand
6. A partly finished sack coat

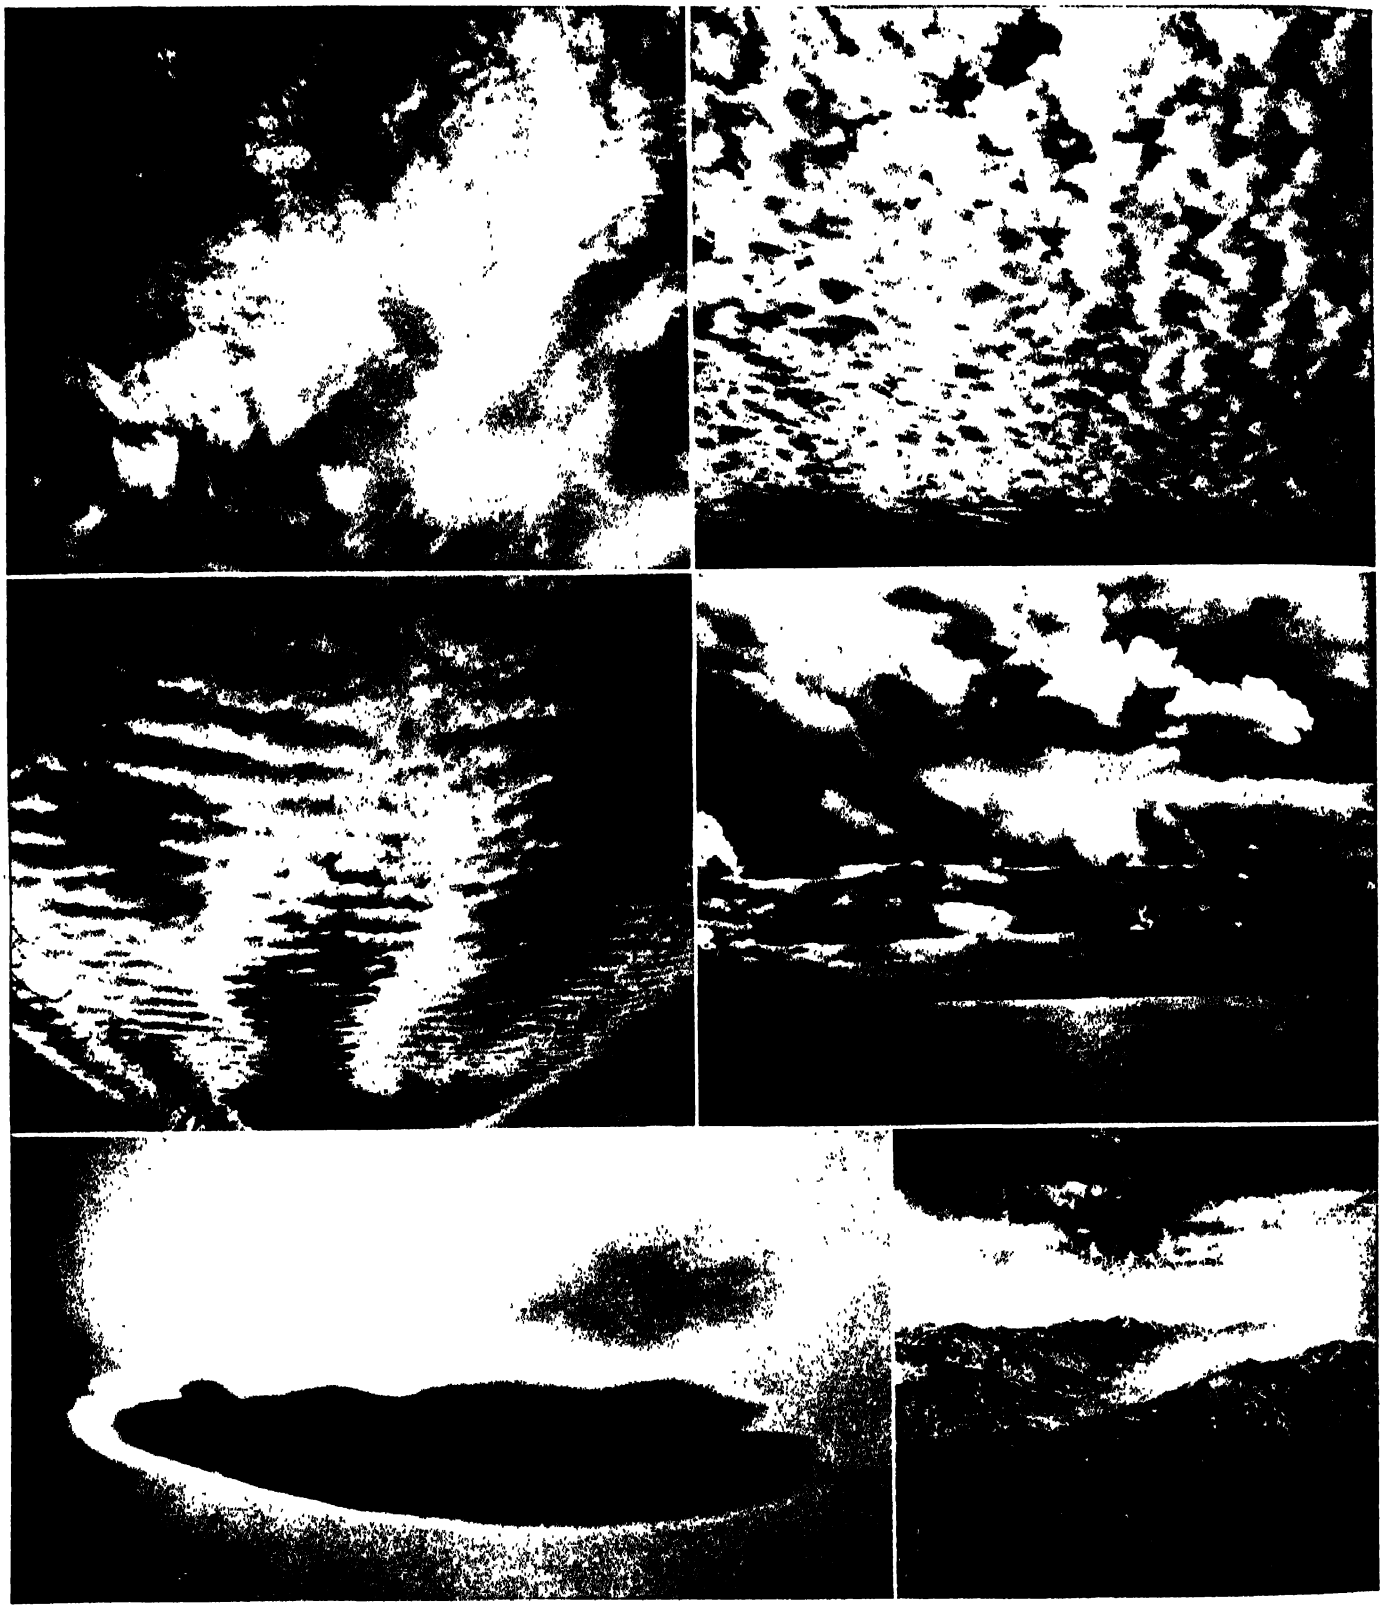
CLOUD

BY COURTESY OF THE UNITED STATES WEATHER BUREAU

CLOUD FORMS

Top left: Cirrus filosus, detached clouds of delicate and fibrous appearance, without shading, white in colour and characterized by more or less straight filaments

Top right: Cirrus uncinus, detached clouds of delicate and fibrous appearance, without shading, white in colour and shaped like a comma, with the upper parts ending in little tufts or points



Centre left: Cirrus densus, detached clouds of fibrous appearance, generally white in colour but sometimes with such thickness that they superficially resemble middle or low clouds

Centre right: Cirrus nothus, dense cirrus streaming out from a cumulo-nimbus cloud and composed of the remains of the frozen upper parts of that cloud

Bottom left: Cirro-stratus nebulosus, a uniform, whitish, misty veil which does not blur the outlines of the sun or moon and usually gives rise to halos

Bottom right: Cirro-stratus filosus, a white fibrous veil, in which more or less definite strands are apparent. It often resembles a sheet of cirrus densus, from which it may actually originate

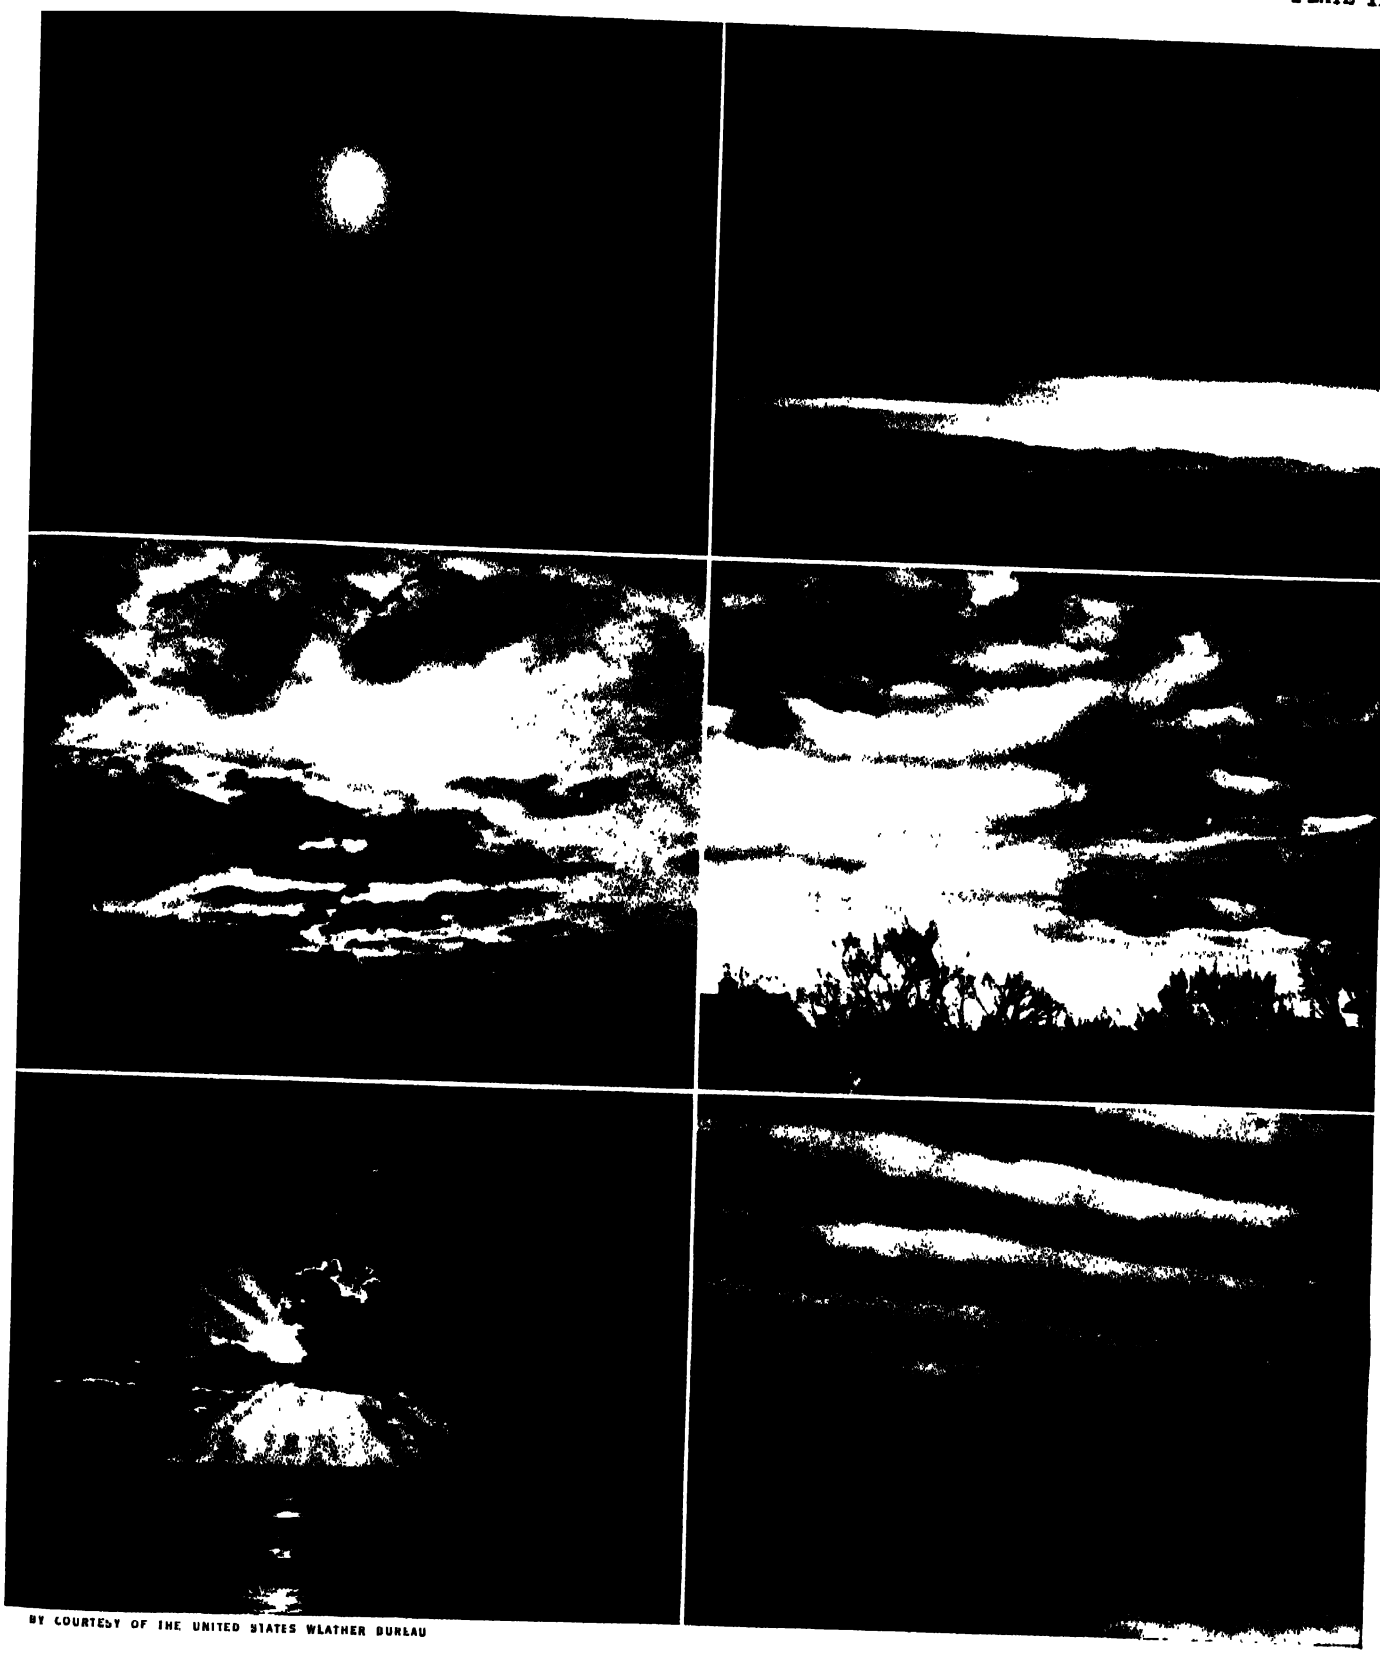
CLOUD

BY COURTESY OF (TOP TO BOTTOM) THE UNITED STATES WEATHER BUREAU PHOTOGRAPH (CENTRE LEFT) A. C. LAPSLEY

CLOUD FORMS

Top left: Cirro-cumulus, a layer or patch composed of small white flakes or small globular masses, without shadows, which are here arranged in groups and associated with tufted cirrus

Top right: Alto-cumulus-translucidus, a layer (or patches) composed of slightly flattened globular masses, with or without shading. The elements are here more or less regularly arranged and are distinct from each other. Blue sky shows through the interstices



Centre left: Alto-cumulus-opacus, a continuous layer consisting of dark and more or less irregular elements which, though opaque, stand out in real relief on the lower surface of the cloud sheet

Centre right: Alto-cumulus-cumulogenitus, a layer formed by the spreading out of the tops of cumulus clouds, and in the first stages of development having the appearance of alto-cumulus-opacus

Bottom left: Alto-cumulus-lenticularis, small isolated patches, with or without shading, and roughly in the shape of a double convex lens

Bottom right: Alto-cumulus-castellatus, cloud masses with more or less vertical development, here visible in the upper part of the picture. The elements are generally arranged in a line and rest on a common horizontal base, thus giving the cloud a crenellated appearance

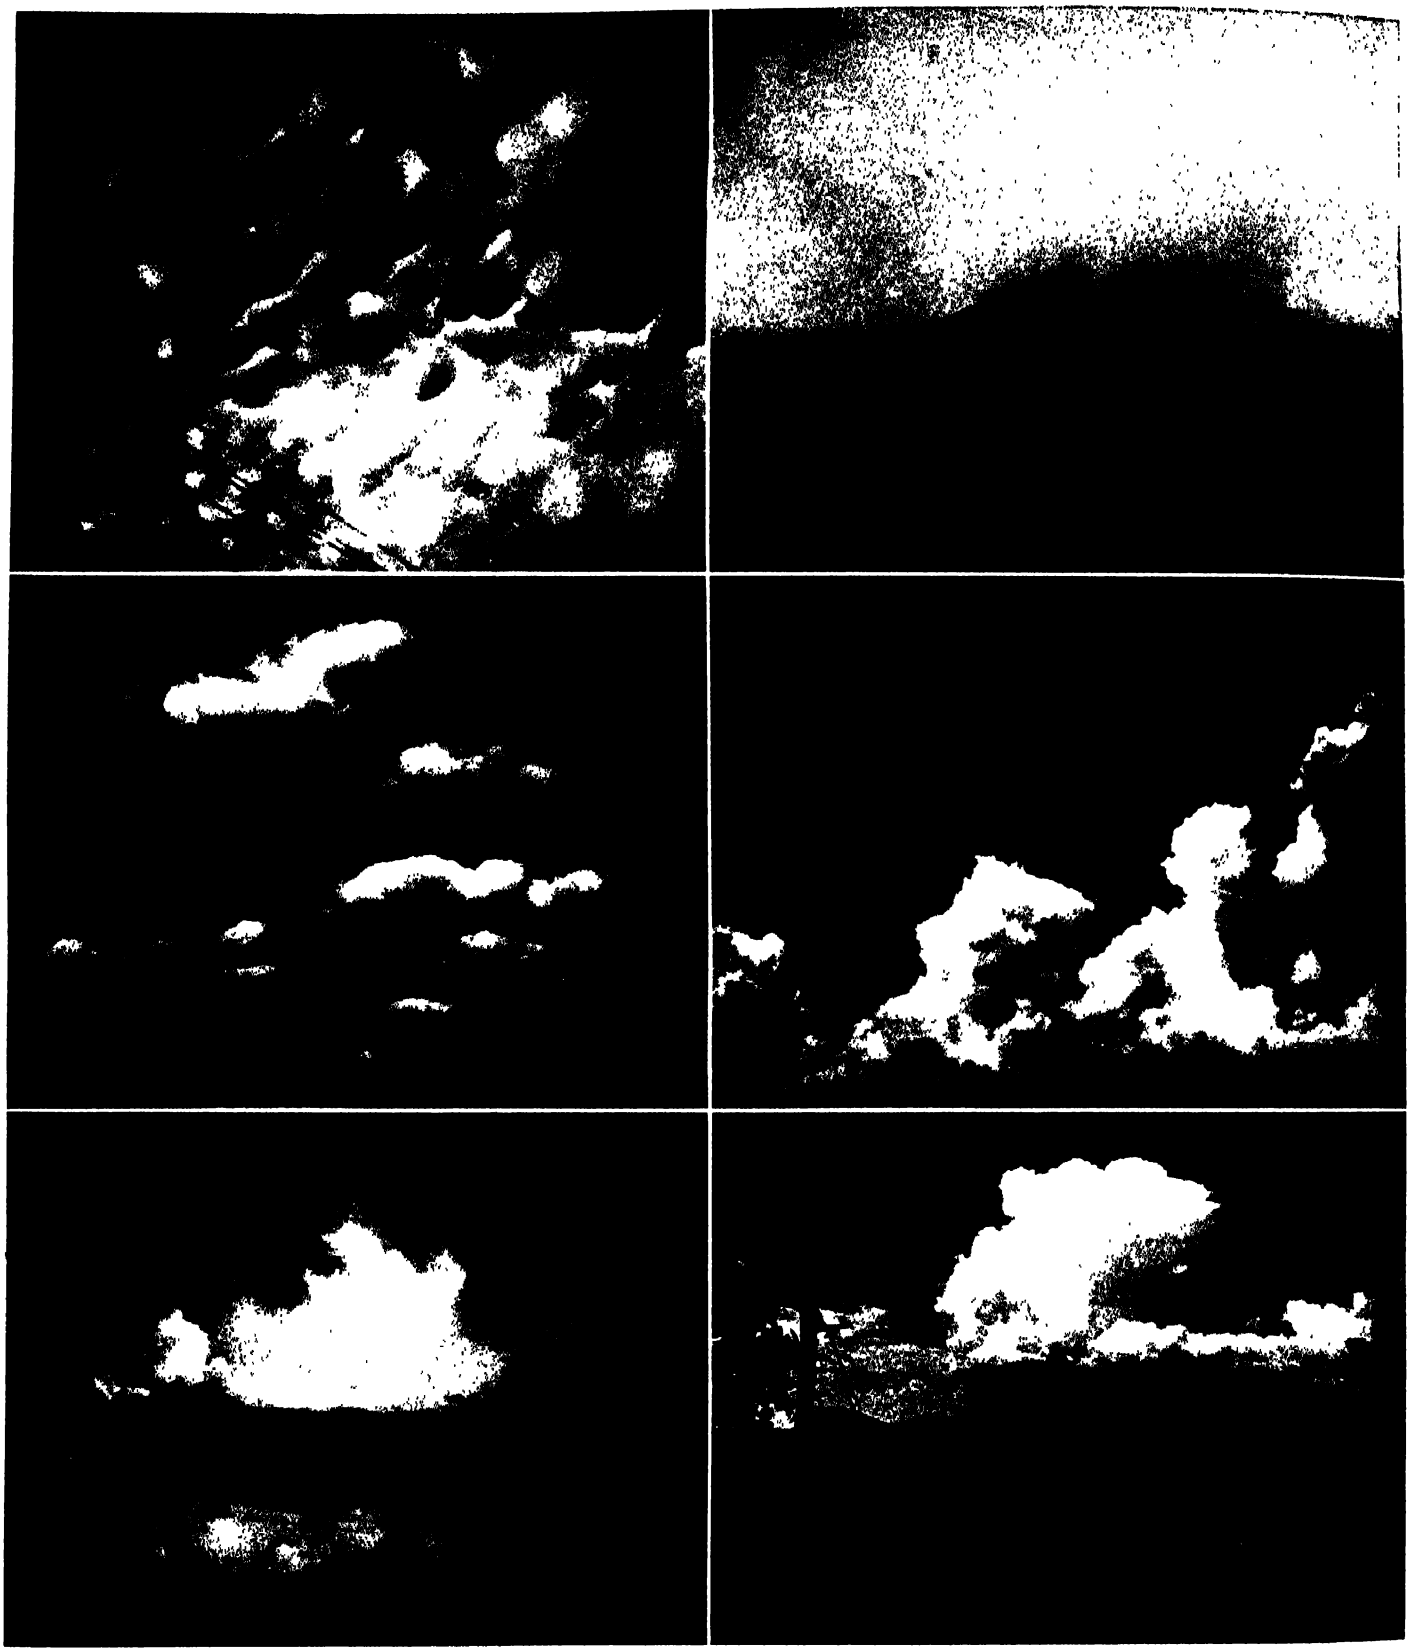
CLOUD

BY COURTESY OF THE UNITED STATES WEATHER BUREAU

CLOUD FORMS

Top left: Alto-stratus-translucidus, a striated or fibrous veil, grayish in colour, here seen above small masses of low cloud. The veil resembles thick cirro-stratus but does not produce halo phenomena; the sun or moon shines faintly, as though through ground glass

Top right: Alto-stratus-opacus, an opaque, fibrous veil, gray or bluish in colour. Its thickness is variable, but generally it is dense enough to hide completely the sun or moon



Centre left: Strato-cumulus-translucidus, a layer (or patches) composed of globular masses or rolls which are soft and gray, with darker parts. The interstices between the cloud elements permit the passage of sunlight

Centre right: Strato-cumulus-opacus, a thick layer made up of a continuous sheet of large dark rolls or rounded masses; their shape is not clearly defined, but they stand out in relief from the undersurface of the layer

Bottom left: Strato-cumulus-vesperalis, flat, elongated masses or rolls of cloud which are often seen to form about sunset

Bottom right: Strato-cumulus-undulatus, a dense, dark layer composed of large, lumpy rolls which cover the whole sky and are aligned in one direction only. Often called roll cumulus

CLOUD

BY COURTESY OF THE UNITED STATES WEATHER BUREAU

CLOUD FORMS

Top left: Strato-cumulus-mammatus, a layer composed of dense globular masses whose lower surfaces form a series of pouches or festoons

Top right: Stratus, a low uniform layer of cloud, resembling fog but not resting on the ground

Centre left: Cumulus humilis, clouds with vertical development but with a tendency toward flattening of the dome-shaped tops. They are generally seen in fine weather

Centre right: Cumulus congestus, thick clouds with vertical development and having a distended and swollen appearance. The upper surfaces are dome shaped and exhibit cauliflowerlike protuberances

Bottom left: Cumulo-nimbus-capillatus, heavy masses of cloud with great vertical development, from which showers fall; the upper parts have a fibrous structure and generally spread out in the shape of an anvil

Bottom right: Cumulo-nimbus-calvus, heavy masses of cloud with great vertical development, from which showers fall but which are not characterized by any pronounced fibrous structure in the upper parts

for 7 out of 10 genera, and 7 general varieties that can apply to many of the species. The classification of cloud forms fixed by international agreement is outlined below:

A. High clouds (mean lower level 6,000 m. [19,685 ft.])
   1. Cirrus
   2. Cirrocumulus
   3. Cirrostratus
B. Middle clouds (mean upper level 6,000 m. [19,685 ft.], mean lower level 2,000 m. [6,562 ft.])
   4. Altocumulus
   5. Altostratus
C. Low clouds (mean upper level 2,000 m. [6,562 ft.], mean lower level close to the ground)
   6. Stratocumulus
   7. Stratus
   8. Nimbostratus
D. Clouds with vertical development (mean upper level that of the cirrus, mean lower level 500 m. [1,640 ft.])
   9. Cumulus
   10. Cumulonimbus

The definitions and descriptions of the ten cloud genera given in the *International Atlas* may be summarized as follows:

1. Cirrus (Ci).—Detached clouds of delicate and fibrous appearance, without shading, generally white in colour, often of a silky appearance. Cirrus manifests itself in various forms such as isolated tufts, lines drawn across a blue sky, branching feather-like plumes, curved lines ending in tufts, etc.; it often is arranged in bands, which, because of the effect of perspective, converge to a point on the horizon.

2. Cirrocumulus (Cc).—A layer or patch composed of small white flakes or of very small globular masses, without shading, which are arranged in groups or lines, or in ripples resembling those of the sand on the seashore.

3. Cirrostratus (Cs).—A thin whitish veil which does not blur the outlines of the sun or moon but produces halos. Sometimes it is quite diffuse and merely gives the sky a milky look; sometimes it more or less distinctly shows a fibrous structure.

4. Altocumulus (Ac).—A layer (or patches) composed of slightly flattened globular masses, the smallest elements being fairly narrow and thin, with or without shading. These elements are arranged in groups, lines or waves, following one or two directions and are sometimes so close together that their edges join.

5. Altostratus (As).—A striated or fibrous veil, more or less gray or bluish in colour. Sometimes this cloud is like dense cirrostratus, but without halo phenomena; the sun or moon shows dimly, as though through ground glass. At other times it is very thick and dark, and may even completely hide the sun or moon.

6. Stratocumulus (Sc).—A layer (or patches) composed of globular masses which are soft and gray, with darker parts. These elements, the smallest of which are fairly broad, are arranged in groups, lines, or in waves aligned in one or two directions. Often the rolls are so close that their edges join; when they cover the whole sky, they have a wavy appearance.

7. Stratus (St).—A low uniform layer of cloud, resembling fog but not resting on the ground.

8. Nimbostratus (Ns).—A low amorphous layer, rainy in appearance, dark gray in colour, nearly uniform in texture and feebly illuminated, seemingly from inside. It usually, but not necessarily, yields precipitation.

9. Cumulus (Cu).—Thick clouds with vertical development, the upper surfaces of which are dome shaped and exhibit protuberances while the bases are nearly horizontal.

10. Cumulonimbus (Cb).—Heavy masses of cloud, with great vertical development, whose summits rise like mountains or towers, the upper parts having a fibrous texture and often spreading out in the shape of an anvil.

PHYSICS OF CLOUDS

Almost all types of clouds result from the process of condensation, during which some of the water vapour present in the air changes to liquid water in the form of minute drops. (The average diameter of the droplets composing a cloud is of the order of magnitude of .001 in.) Condensation depends upon the fact that for a given temperature there is a maximum pressure that can be exerted by water vapour. The lower the temperature, the smaller is this maximum pressure. If, for any reason, a body of cloudless air becomes cooled below the temperature corresponding to that at which the existing pressure of water vapour represents the maximum permissible value, condensation and cloud formation are initiated. The temperature at which the maximum permissible vapour pressure matches the existing vapour pressure is known as the dew point. (*See* DEW.)

Although laboratory experiments have shown that condensation does not necessarily occur in perfectly pure air that has been cooled below the dew point, the atmosphere contains a variety of impurities which facilitate the change from vapour to liquid. These impurities may be divided into two groups: (1) tiny particles of simple solids, such as dust and smoke; and (2) submicroscopically small particles of certain hygroscopic substances, notably sea salts, sulphuric acid and nitrous acid. The first group appears to be relatively unimportant in the promotion of condensation, whereas particles of the second group serve as nuclei around which cloud droplets grow readily whenever the temperature of the air becomes lower than the dew point.

The manner in which ice-crystal clouds (*i.e.*, clouds of the cirrus family) are created is not well understood. Ice crystals may be produced in the atmosphere either by the freezing of liquid water or by the direct transition of water from the vapour state to the solid state. (The latter process is termed sublimation.) However, it is known that ice crystals will not form directly from water vapour unless the temperature is lower than about 20° F. Even at temperatures well below 0° F. liquid droplets are formed more commonly than ice crystals. Therefore, it is believed that cirrus clouds arise mainly from the freezing of liquid water previously produced by the process of condensation. Laboratory experiments have given evidence that at low temperatures solid, rather than hygroscopic, particles serve as nuclei for condensation.

As already stated, condensation depends upon a reduction of the air temperature to a value lower than the dew point. Such reduction may be brought about in the following ways: (1) loss of heat by conduction; (2) loss of heat by radiation; (3) adiabatic cooling of air by reduction of pressure because of ascent. The first two processes, although important in the formation of fog, play comparatively insignificant roles in respect to cloud formation. Adiabatic cooling of ascending air is the basic cause of almost all clouds; the nature of the ascending motion determines the character of the clouds.

There are four general classes of upward motion: (1) vertical currents of small dimensions and irregular structure superimposed on the horizontal flow of air; (2) large-scale convection currents; (3) upward currents induced by orographic obstacles in the path of the wind; (4) more or less uniform ascent of air over wide areas resulting from special dynamical conditions in the atmosphere. The first of these classes of motion yields stratus and a few varieties of stratocumulus. The second class produces the clouds that are distinguished by their marked vertical development (*i.e.*, cumulus and cumulonimbus, from which certain forms of high clouds and middle clouds, notably cirrus nothus and altocumulus cumulogenitus, as well as most types of stratocumulus, are derived). The third class typically gives rise to stratus or to altocumulus lenticularis, but complications are often introduced by the fact, that such currents will accentuate any pre-existing tendency toward large-scale convection, with the result that clouds having considerable vertical development may be generated by this type of upward motion. As for the uniform ascent of air over large areas, special importance must be attached to this fourth class of motion, because it leads to the formation of the unbroken sheets of cirrostratus, altocumulus and altostratus which ordinarily precede bad weather.

The principal process that brings about the disappearance of existing clouds is exactly the reverse of that to which they owe their formation. An increase in the temperature of the air to a value above the dew point initiates vaporization and causes some or all of the water droplets or ice particles composing the clouds to vanish. The ways in which a body of air may have its temperature raised are the following: (1) gain of heat by conduction, (2)

gain of heat by radiation, (3) adiabatic warming of air by increase of pressure because of descent. Of these, adiabatic warming of descending air is the most effective mechanism by which clouds are evaporated.

The circumstances in which air descends may be grouped into three classifications: (1) there is localized descending motion of air whenever large-scale convection is taking place, which accounts for the fact that cumulus clouds are separated by clear spaces; (2) descent of air occurs in the lee of orographic obstacles and, in general, over sloping terrain when the wind blows in a downhill direction; (3) a slow, uniform and widespread sinking of air develops under certain dynamical conditions; this may give cloudless skies over a large area. (G. Es.)

MEASUREMENT OF CLOUD HEIGHT

A knowledge of the height of the clouds is obviously of much importance to pure meteorology and also is an aid to flying. For the latter purpose it is especially important to know the height of the lower surface or base of the cloud. In the United States and Canada the term "ceiling" is used to denote the height of the base of the lowest clouds present in quantity on any occasion. "Ceiling zero" is reported when the ceiling is 50 ft. or less; "ceiling unlimited" is reported when either no broken or overcast layer is observed, or the base of the lowest reported broken or overcast layer is higher than 9,750 ft. above ground.

Modern techniques for measuring the base of clouds employ such devices as ceiling balloons, ceiling light projectors, ceilometers and very short wave length (1 cm.) radar. In addition, cloud heights have been estimated by triangulation methods, by optical range finders, by intersections of clouds with hills or mountains, and by application of the dew point formula. In the latter method, when the air is thoroughly mixed as far as the base of the cloud, the height of the condensation level may be calculated from the surface temperature θ and the dew point temperature θ_d (*see* HUMIDITY, ATMOSPHERIC) by the formula

$$Z = 220\ (\theta - \theta_d)\ \text{ft.}\ (\theta \text{ and } \theta_d \text{ in } ^\circ\text{F.})$$

The cloud base is usually 100 to 200 ft. higher than the condensation level, but large errors can occur in such estimates.

In the ceiling balloon method, a small neoprene balloon coloured red or purple for good contrast and weighing about 10 g. is inflated with helium to a free lift of 45 g. and released. With this lifting power, the balloon has an average ascensional rate of about 400 ft. per minute. The height of the cloud can now be computed by noting the time required for the balloon to enter the base of the cloud. The accuracy of the method is limited by the accuracy of the assumed ascensional rate. Unfortunately, the rate becomes very erratic when the clouds are scattered or broken because of the presence of vertical air currents.

For nighttime observations a light (flashlight and battery) can be attached to the ceiling balloon. However, a much more accurate and convenient method is available for ceiling measurements during the hours of darkness through the use of the ceiling light projector. In this device a small searchlight projects a narrow beam of light, of less than 3° spread, vertically upward to the base of the cloud. An observer located 500 to 1,000 ft. from the projection sights on the spot of light on the lower surface of the cloud and measures the vertical angle, h, to the spot. If L is the base line distance from observer to projector, then the height of the cloud base is

$$Z = L \tan h$$

The accuracy of this method is adequate for airways' purposes, being limited chiefly by the uniformity of the underside of the cloud and by the accuracy with which the vertical angle can be measured. With a 500-ft. base line, an uncertainty of 2° in angle will give an error of about 240 ft. for a cloud height of 2,000 ft. Under ideal conditions cloud heights up to 15,000 ft. have been determined to an accuracy of about 2,500 ft.

In daylight the spot from the cloud searchlight is, of course, entirely invisible against the sky, which may be about 1,000,000 times as bright as the spot. This difficulty has been resolved by using a light, modulated to a known frequency, and observing the spot by means of a special telescope which has a photoelectric cell at the focus of a large lens. Electrical filters used in conjunction with the photoelectric cell reject all signals except those of the modulating frequency. These electrical signals are then amplified sufficiently to operate a standard electrical meter. This device, known as the ceilometer, can measure cloud heights to 10,000 ft. during the daytime and about 20,000 ft. at night. It is widely employed not only at civilian air terminals but by the various military services.

Another possibility, still somewhat experimental in the early 1950s, is to project a short pulse of light and measure the time required for it to return to the point of observation. Light pulses of about one-microsecond (one millionth of a second) duration are produced by a high-voltage spark placed at the focus of a good quality 36-inch Cassegrain mirror. The light pulse reflected from a cloud deck is then received by a second mirror which focuses the light on a photocell. Since light travels about 982 ft. per microsecond (186,000 mi. per second), it is necessary to measure accurately time intervals of a few microseconds. As a result of advances during World War II, time intervals to 100th of a microsecond can be measured. It is estimated that a high flux of about 4,000,000 lumens is placed on the cloud deck during measurement. With some experimental models, clouds up to 18,000 ft. were detected in daylight.

A knowledge of the vertical extent and structure of clouds is of great importance to aviation and meteorological science. Some information was formerly obtained from reports of pilots. Radar equipment was later designed that not only measured the base of selected clouds but also permitted detailed study of the vertical structure of clouds. It has been shown both theoretically and experimentally that microwaves of approximately one centimetre wave length are scattered by cloud water droplets of radii between 10 and 30 microns. Short microwave pulses of few microseconds duration are radiated vertically upward toward the cloud from a parabolic antenna mirror six feet in diameter. These pulses are then scattered back toward the antenna from the top and bottom of successive layers of clouds. The time interval between the transmission of the pulse and the returned cloud echo is measured. If this time interval is t microseconds, then the height, Z, of the echoing surface from the radar set is

$$Z = 982 \times \frac{t}{2}\ \text{ft.}$$

Radar sets operating at these short wave lengths have detected clouds to heights in excess of 45,000 ft. It has also been possible to locate clouds through several thousand of feet of light rain. However, the minimum altitude that can be detected is about 800 ft., this limitation being due to the recovery time of the radar receiver. The development of the radar cloud-base and cloud-top indicator represents one of the most significant advances in meteorological instrumentation after 1932.

(W. E. K. M.; ML. FE.)

CLOUDBERRY, *Rubus Chamaemorus,* a low-growing creeping herbaceous plant (family, Rosaceae) with simple obtusely lobed leaves and solitary white flowers, resembling those of the blackberry, but larger—one inch across—and with stamens and pistils on different plants. The orange-yellow fruit is about half an inch long and consists of a few large drupes with a pleasant flavour. The plant occurs in the mountainous parts of Great Britain, and is widely distributed through the more northerly portions of both hemispheres. In North America it grows in peat bogs and on mountains from Maine and New Hampshire to arctic America and westward to Alaska and British Columbia. In Norway and Sweden the fruit is gathered in large quantities and sold in the markets.

CLOUDBURST, a term popularly applied to an excessively heavy fall of rain, usually of brief duration, over a small area of the earth's surface. Most so-called cloudbursts occur in connection with thunderstorms. In these storms there are violent uprushes of air, which at times prevent the condensing raindrops from falling to the ground. A large amount of water may thus

accumulate at high levels, and if the upward currents are weakened the whole of this water falls at one time. Cloudbursts are especially common in mountainous districts. This is probably because the rising air currents of a thunderstorm are more or less broken up by the passage of the storm over a mountain. The effects of heavy rain are especially striking on mountain slopes because the falling water is concentrated in valleys and gulleys. Mountain cloudbursts cause sudden and destructive floods. The intensity of rainfall in the most severe cloudbursts can only be conjectured. A rainfall of 2.47 in. in 3 min. was registered by an automatic raingauge at Porto Bello, Panama, on Nov. 29, 1911, and one of 1.02 in. in 1 min. by two automatic gauges, placed side by side, at Opid's camp, on the west front of the San Gabriel Range, Calif., on April 5, 1926. There have been many cases, however, in which the deep excavations made in the ground by the falling water of a cloudburst appear to indicate a much greater intensity of rainfall than in the cases above noted.

CLOUDED LEOPARD, a large arboreal cat (*Neofelis nebulosa*) found in southeast Asia, Sumatra, Java, Borneo and Formosa. This cat, also called the clouded tiger, is beautifully marked with large dark patches edged with black. It has an elongate head and body (about 3 ft.), the tail nearly as long, and rather short limbs. The upper canine teeth are proportionately longer than in other living cats. Although its pattern resembles that of the marbled cat (*Felis marmorata*), they are not closely related. The clouded leopard preys on small mammals and birds. (J. E. Hl.)

CLOUET, FRANÇOIS (d. 1572), French miniature painter. The earliest reference to him is the document dated Dec. 1541 (*see* Clouet, Jean), in which the king renounces for the benefit of the artist his father's estate which had escheated to the crown as the estate of a foreigner. In it the younger Janet is said to have "followed his father very closely in the science of his art." Like his father, he held the office of groom of the chamber and painter in ordinary to the king, and so far as salary is concerned, he started where his father left off. A long list of drawings contains those which are attributed to this artist, but we still lack perfect certainty about his works. There is, however, more to go upon than there was in the case of his father, as the praises of François Clouet were sung by the writers of the day, his name was carefully preserved from reign to reign, and there is an ancient and unbroken tradition in the attribution of many of his pictures. There are not, however, any original attestations of his works, nor are any documents known which would guarantee the ascriptions usually accepted. To him are attributed the portraits of Francis I at the Uffizi, Florence, and at the Louvre, and drawings relating to them. He probably also painted the portrait of Catherine de' Medici at Versailles and other works, and in all probability a large number of the drawings ascribed to him were from his hand. One of his most remarkable portraits is that of Mary, queen of Scots, a drawing in chalks in the Bibliothèque Nationale, Paris, and of similar character are the two portraits of Charles IX and the one at Chantilly of Marguerite of France. Perhaps his masterpiece is the portrait of Elizabeth of Austria in the Louvre.

In 1568 he is known to have been under the patronage of Claude Gouffier de Boisy, Seigneur d'Oiron and his wife Claude de Baune. Another ascertained fact concerning François Clouet is that in 1571 he was "summoned to the office of the Court of the Mint," and his opinion was taken on the likeness to the king of a portrait struck by the mint. He prepared the death mask of Henry II, as in 1547 he had taken a similar mask of the face and hands of Francis I, in order that the effigy to be used at the funeral might be prepared from his drawings; and on each of these occasions he executed the painting to be used in the church decorations and the banners for the ceremony.

Several miniatures are believed to be his work, one remarkable portrait being the half-length figure of Henry II in the collection of the late J. Pierpont Morgan. Another of his portraits is that of the duc d'Alençon in the Jones collection at South Kensington, and certain representations of members of the royal family which were in the Hamilton palace collection and the Magniac sale are usually ascribed to him. He died on Dec. 22, 1572, shortly after the massacre of St. Bartholomew, and his will, mentioning his sister and his two illegitimate daughters, and dealing with the disposition of a considerable amount of property, is still in existence. His daughters became nuns. Like his father, he was known as Janet. His work is remarkable for the accuracy of the drawing, the elaborate finish of all the details, and the completeness of the whole portrait. He must have been a man of high intelligence, and great penetration, intensely interested in his work, and with considerable ability to represent the character of his sitter in his portraits. His colouring is not specially remarkable, nor from the point of style can his pictures be considered specially beautiful, but in perfection of drawing he has hardly any equal. (G. C. W.)

CLOUET, JEAN (1485–1541?), French miniature painter, generally known as Janet. The authentic presence of this artist at the French court is first to be noted in 1516, the second year of the reign of Francis I. By a deed of gift made by the king to the artist's son of his father's estate, which had escheated to the crown, we learn that he was not actually a Frenchman, and never even naturalized. He is supposed to have been a native of the Low Countries, and probably his real name was Clowet. His position was that of groom of the chamber to the king, and he received a stipend at first of 180 livres and later of 240. He lived several years in Tours, and there it was he met his wife, who was the daughter of a jeweller. He is recorded as living in Tours in 1522, and there is a reference to his wife's residence in the same town in 1523, but in 1529 they were both settled in Paris, probably in the neighbourhood of the parish of St. Innocent, in the cemetery of which they were buried. He stood godfather at a christening on July 8, 1540, but was no longer living in Dec. 1541, and therefore died between those two dates.

His brother, known as Clouet de Navarre, was in the service of Marguérite d'Angoulême, sister of Francis I, and is referred to in a letter written by Marguérite about 1529. Jean Clouet had two children, François and Catherine, who married Abel Foulon, and left one son, who continued the profession of François Clouet after his decease. Jean Clouet was undoubtedly a very skilful portrait painter, but it must be acknowledged without hesitation that there is no work in existence which has been proved to be his. There is no doubt that he painted a portrait of the mathematician, Oronce Finé, in 1530, when Finé was 36 years old, but the portrait is now known only by a print. Janet is generally believed, however, to have been responsible for a very large number of the wonderful portrait drawings now preserved at Chantilly, and at the Bibliothèque Nationale, Paris, and to him is attributed the portrait of an unknown man at Hampton Court, that of the dauphin Francis, son of Francis I at Antwerp, and one other portrait, that of Francis I in the Louvre. Seven miniature portraits in the *Manuscript of the Gallic War* in the Bibliothèque Nationale (13,429) are attributed to Janet with very strong probability, and to these may be added an eighth in the collection of the late J. Pierpont Morgan, and representing Charles de Cossé, Maréchal de Brissac, identical in its characteristics with the seven already known. There are other miniatures in the Morgan collection, which may be attributed to Jean Clouet with some strong degree of probability, inasmuch as they closely resemble the portrait drawings at Chantilly and in Paris which are taken to be his work. In his oil paintings the execution is delicate and smooth, the outlines hard, the texture pure, and the whole work elaborately and very highly finished in rich, limpid colour. The chalk drawings are of remarkable excellence, the medium being used by the artist with perfect ease and absolute sureness, and the mingling of colour being in exquisite taste, the modelling exceedingly subtle, and the drawing careful, tender and emphatic. The collection of drawings preserved in France, and attributed to this artist and his school, comprises portraits of all the important persons of the time of Francis I. In one album of drawings the portraits are annotated by the king himself, and his merry reflections, stinging taunts or biting satires, add very largely to a proper understanding of the life of his time and court. Definite evidence, however, is still lacking to establish the attribution of the best of these drawings and of certain oil paintings to the Jean Clouet who was groom of the chambers to the king.

The chief authority in France on the work of this artist is Louis Dimier. *See* also E. Moreau-Nelaton, *Les Clouets et leurs émulés* (1921). (G. C. W.)

CLOUGH, ANNE JEMIMA (klŭf) (1820–1892), educationalist and sister of the poet, Arthur Hugh Clough, born at Liverpool Jan. 20, 1820. When two years old she went with her family to Charleston, U.S.A., but returned to England in 1836. Her father's failure in business led her to open a school in 1841 which was carried on until 1846. In 1852, after studying in London and working at the Borough road and the Home and Colonial schools, she opened another school at Ambleside, in Westmorland. Keenly interested in the education of women, she made friends with Miss Emily Davies, Madame Bodichon, Miss Buss and others. After helping to found the North of England council for promoting the higher education of women, she acted as its secretary from 1867–70 and as president from 1873–74. When it was decided to open a house for women students at Cambridge, Miss Clough was chosen as its first principal. This hostel, started in Regent street, Cambridge, in 1871 with five students, and continued at Merton hall in 1872, led to the building of Newnham hall, opened in 1875, and to the erection of the present Newnham college, Cambridge, in 1880. Miss Clough's personal charm and high aims, together with her work at Newnham college, made her one of the leaders of the women's educational movement. She died on Feb. 27, 1892.

See B. A. Clough, *Memoir of Anne Jemima Clough* (1903).

CLOUGH, ARTHUR HUGH (1819–1861), English poet, was born at Liverpool on Jan. 1, 1819. In 1822 his father, a cotton merchant, moved to the United States, and Clough's childhood was spent mainly at Charleston (S.C.). In 1828 the family visited England, and Clough was left at school at Chester, whence he passed in 1829 to Rugby, then under Dr. Thomas Arnold. In 1837 he went with a scholarship to Balliol college, Oxford. Here his contemporaries included Benjamin Jowett, A. P. Stanley, J. C. Shairp, W. G. Ward, Frederick Temple and Matthew Arnold. Clough missed a Balliol fellowship, but obtained one at Oriel, with a tutorship, and lived the Oxford life of study, speculation, lectures and reading-parties until 1848, when he went abroad, seeing Paris in revolution and Rome in siege. In the autumn of 1849 he became principal of University Hall, a hostel for students at University college, London. He disliked London, in spite of the friendship of the Carlyles, nor did the atmosphere of Unitarianism prove any more congenial than that of Anglican Oxford to his critical and at bottom conservative temper. In 1852 encouraged by Emerson, he went to Cambridge (Mass.). Here he remained some months, lecturing and translating Plutarch for the booksellers, until in 1853 the offer of an examinership in the Education Office brought him to London once more. He married, and pursued a steady official career, diversified only by an appointment in 1856 as secretary to a commission sent to study certain aspects of foreign military education. In 1860 his health began to fail. He visited first Malvern and Freshwater, and then the East, France and Switzerland, in search of recovery, and finally came to Florence, where he died on Nov. 13, 1861. Matthew Arnold wrote upon him the exquisite lament of *Thyrsis*.

Shortly before he left Oxford, in the stress of the Irish potato-famine, Clough wrote an ethical pamphlet addressed to the undergraduates, with the title, *A Consideration of Objections against the Retrenchment Association at Oxford* (1847). His Homeric pastoral *The Bothie of Toper-na-Fuosich*, afterwards re-christened *Tober-na-Vuolich* (1848), was inspired by a long vacation reading-party after he had given up his tutorship, and is an entertaining experiment. *Ambarvalia* (1849), published jointly with his friend Thomas Burbidge, contains shorter poems of various dates from 1840, or earlier, onwards. *Amours de Voyage*, a novel in verse, was written at Rome in 1849; *Dipsychus*, a rather amorphous satire, at Venice in 1850; and the idylls which make up *Mari Magno or Tales on Board*, in 1861. A few lyric and elegiac pieces, later in date than the *Ambarvalia* complete the tale of Clough's poetry. His only considerable enterprise in prose was a revision of the 17th century translation of Plutarch by Dryden and others, which occupied him from 1852, and was published as *Plutarch's Lives* (1859).

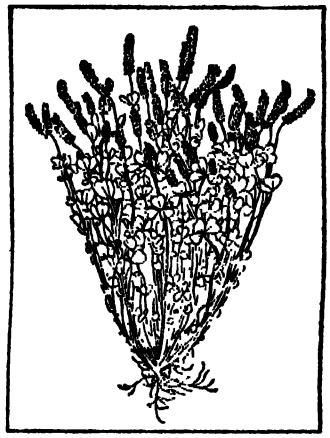
He is rightly regarded, like his friend Matthew Arnold, as one of the most typical English poets of the middle of the 19th century. His critical instincts and strong ethical temper brought him athwart the popular ideals of his day both in conduct and religion. His verse has upon it the melancholy and the perplexity of an age of transition. He is a sceptic who by nature should have been with the believers. He stands between two worlds, watching one crumble behind him, and only able to look forward by the sternest exercise of faith to the reconstruction that lies ahead in the other. On the technical side, Clough's work is interesting to students of metre, owing to the experiments which he made, in the *Bothie* and elsewhere, with English hexameters.

BIBLIOGRAPHY.—Clough's *Poems* were privately collected, with a short memoir by F. T. Palgrave, in 1862; and his *Poems and Prose Remains* with a memoir by his widow in 1869. Selections from the poems were made by Mrs. Clough for the Golden Treasury series in 1894, and by E. Rhys in 1896. *See* monographs by S. Waddington (1883) and J. L. Osborne (1920). Clough's sister Anne Jemima Clough (1820–92) was the first principal of Newnham college, Cambridge.

CLOVELLY, a fishing village of Barnstaple bay, Devonshire, England, 11 mi. W.S.W. of Bideford. Pop. (1931) 528. It is a cluster of old-fashioned cottages in a unique position on the sides of a rocky cleft in the north coast; its main street resembles a staircase, which descends 400ft. to the pier, too steeply to allow of any wheeled traffic. All Saints' church, restored in 1866, is late Norman. The climate is very mild. Thick woods shelter the village on three sides and the surrounding scenery is famous for its richness of colour. Clovelly is described by Dickens in *A Message from the Sea*.

CLOVEN-HOOFED ANIMALS, the popular designation for members of the order Artiodactyla (*q.v.*), which includes the sheep, cattle, deer, antelopes, goats and swine (*qq.v.*).

CLOVER, the English name for plants belonging to the genus *Trifolium*, so-called from the leaf, which has three leaflets (trifoliolate). Clover is a member of the family Leguminosae and contains some 250 species. Many other plants are also called clover, but most of these belong to different genera of the legume family. Species are found on every continent, and in all except Australia certain ones form a part of the native flora. The origin of those species of agricultural importance appears to be south-eastern Europe and southern Asia Minor. The plants are small annual or perennial herbs with trifoliolate (rarely 5 or 7 foliolate) leaves with stipules adnate to the leaf-stalk, and heads or dense spikes of small red, purple, white or yellow flowers or shades thereof; the small few-seeded pods are enclosed in the calyx. Clovers are best adapted to cool humid climates. These may be the summer months of the temperate zones or the winter months of equatorial countries. The perennials may behave as annuals, depending upon the severity of unfavourable climate. Many species are extensively cultivated for hay, pasture and green manure in all countries of the world, while others form an important part of the native vegetation.



COURTESY OF THE BUREAU OF PLANT INDUSTRY, SOILS AND AGRICULTURAL ENGINEERING, U.S. DEPT. OF AGRICULTURE

FLOWER HEADS OF RED CLOVER, *T. PRATENSE*

The most important agricultural species are red clover, *T. pratense*, with round, light to dark purplish red flower heads the most widely cultivated of species from Siberia to Chile, botanically a perennial but agriculturally more of a biennial: white clover, *T. repens*, a creeping, node-rooting perennial, abundant in good pastures meadows and lawns, the most widely naturalized species, with flowers, borne on small round heads, white to pinkish, becoming brown and reflexing as the seed matures; alsike clover, *T.*

hybridum, common in meadows and moist habitats, botanically a perennial but under agricultural conditions mostly a biennial, with flower heads resembling those of white clover; crimson clover, *T. incarnatum*, with pointed heads of bright crimson flowers, a winter annual in climates where winters are not severe, or a restricted summer annual in high latitudes; low hop clover, *T. procumbens*, mostly a winter annual widely naturalized in pastures and along roadsides, with small round heads of bright yellow flowers; least hop clover, *T. dubium*, in Europe synonymous with *T. minus* and commonly called shamrock, similar in all respects to low hop clover but with smaller and fewer flowers per head; sub clover, *T. subterraneum*, a winter annual with decumbent stems, and heads of few, cream-coloured flowers borne inconspicuously under the foliage (after fertilization the flowers reflex and bury the developing seed under the surface of the soil); Persian clover, *T. resupinatum*, mostly a winter annual, having small flat heads of lavender flowers with calyx inflating as maturing; strawberry clover, *T. fragiferum*, a creeping, node-rooting perennial with round, slightly pointed heads, with pinkish flowers, calyx inflating as maturing, tolerant to soil salinity, preferring moist habitats; berseem clover, *T. alexandrinum*, a winter annual having spike-like heads of white to cream flowers, not tolerant of heavy frosts; and cluster clover, *T glomeratum*, a winter annual having small round heads of dull rose coloured inconspicuous flowers, with heads borne on short stems in leaf axils, rough and spine-like upon maturity

CRIMSON CLOVER, T. INCARNATUM

Clover was cultivated in the Netherlands about the middle of the 16th century and it is possible that its culture occurred among the ancient Letts a thousand years earlier. It was originally introduced from Flanders into England as a field crop about the middle of the 17th century by Sir Richard Weston. He has the distinction of being the first to introduce into England the rotation of crops, using clover as a soil improving crop. Clovers are grown alone or in mixtures with different grasses and other legumes. They thrive in soils having a high content of phosphorus, calcium and potassium, either of natural origin or supplied by fertilizers. The forage is highly palatable to livestock and is high in protein and in phosphorus and calcium, thus making valuable livestock feed either in the green or dry stage and a good soil improving crop when plowed under as green manure.

Many varieties and strains of each species occur, representing forms best adapted to the environments where grown. These were developed principally by natural selection through the survival of the fittest. No authentic hybrids between species are known. The basic chromosome numbers of the genus appear to be seven and eight. Of the species studied, the somatic numbers of chromosomes range from 14 to about 130. Many of the important species such as red clover, white clover and alsike clover are principally self-sterile. Cross pollination resulting in seed setting is brought about by insect visits, principally bees, which visit the flowers for nectar and pollen. Other species such as the hop clovers and Persian clover are self-fertile, self-pollinating, while still others, such as crimson clover, are self-fertile but not self-pollinated.

Diseases and insects play an important role in the production of clovers, affecting the length of life of the plant and its reproduction; many are world-wide where clovers occur, while others are limited to specific countries. The length of the photoperiod where the strain or variety originates also has an important relationship to its adaptation in different locations.

All of the above mentioned clovers are grown in the United States. Berseem clover is grown only in limited places of southern Arizona and California; cluster clover in localities of Mississippi, Georgia, Louisiana and Alabama; sub clover in the coastal section of the Pacific states and limited areas of the southern states. The other, more widely grown species are Persian, on the heavy low-lying soils of the southern states; the hop clovers from Kentucky southward and the Pacific northwest; strawberry clover throughout the irrigated lands of the western states; crimson clover from New Jersey and Kentucky southward as a winter annual and in Northern Maine as a summer annual; white clover in all states where there is sufficient moisture and required plant foods; Ladino clover, a large-growing variety of white clover of major importance in the northeastern and western states which appears to have a place in the lake and south Atlantic states. The principal red clover belt is east of 98° longitude and north of 35° latitude, in the Pacific northwest and irrigated lands of the western states; and alsike clover is in the same general region.

Cultivation.—Red clover and alsike clover are generally seeded with companion grain crops. If adequate moisture is available after the harvesting of the grain, light grazing or a small hay crop may be produced the first year. The heavy crop occurs from the second year's growth. If seeded with grass the stands are usually left through the third year; otherwise the aftermath is plowed under for cultivated row crops in the fall of the second year or the next spring. Failures to establish and maintain stands may be due to improper seed bed preparation, heavy seedings of rank, late-maturing grain crops, deficiencies of plant foods, phosphorus, potassium and calcium, diseases and insects and the use of unadapted varieties and strains. Most of the other clovers are used principally for pastures and are seeded on turf or with grasses. Successful seedings are obtained more generally when the grass is closely grazed or clipped and where adequate quantities of phosphate and potash fertilizers and limestone are applied.

In America two common forms of red clover are recognized, medium and mammoth, better called double- and single-cut respectively. These are comparable with but not the same as the English double-cut and single-cut clovers. To conditions in the U.S. none of the European clovers is adapted, and their use leads to poor stands and low yields. Likewise, strains adapted to one section of the red clover belt do poorly in another. Improved varieties are developed by state agricultural experiment stations and the U.S. department of agriculture. Seed of two red clover varieties, Cumberland and Midland, adapted to the southern and central sections of the principal red clover belt, are available. In Canada the Dollard, Ottawa, Altaswede and Manhardy represent improved varieties. No marked differences have been found between strains of alsike clover. White clover strains differ widely, varying from low-growing types to Ladino clover. Strains of crimson clover vary in adaptation. The superiority of certain strains of sub clover brought about its adaptation and increased use in the Pacific northwest.

Red clover seed is produced over most of the main U.S. clover area, and large yields are obtained in the irrigated region of the west. It is commonly taken from the second crop. Alsike clover seed is produced in the same region as red clover seed but is taken from the first crop, since this species does not commonly produce two cuttings in a season. The winter annual species produce seed in the spring and are perpetuated by the seed that volunteers in the fall. White clover seed is produced principally in the southern, midwestern and western states In the humid states the first crop is more generally harvested, while in the west two seed crops are frequently obtained

Upward of 50 native species of clover occur on the Pacific coast and in the Rocky mountain region, but east of the Mississippi river only four native species occur.

See publications of the state agricultural experiment stations and the U.S. department of agriculture. (E. A. H.)

CLOVES, the dried, unexpanded flower-buds of *Eugenia aromatica*, a tree belonging to the family Myrtaceae. The clove tree is a beautiful evergreen which grows to a height of 40 ft., having large oval leaves and crimson flowers in numerous groups of terminal clusters. The flower-buds are at first of a pale colour and gradually become green, after which they develop into a bright red, when they are ready for collecting. Cloves are rather more than half an inch in length and consist of a long cylindrical calyx, terminating in four spreading sepals, and four unopened petals which form a small ball in the centre. The tree is a native of the Moluccas, or Spice Islands, but it was long cultivated by the Dutch in Amboyna and two or three small neighbouring islands. The Portuguese, by doubling the Cape of Good Hope, obtained possession of the principal portion of the clove trade, which they continued to hold for nearly a century, when, in 1605, they were expelled from the Moluccas by the Dutch. Holland exerted great efforts to obtain a complete monopoly of the trade, attempting to extirpate all the clove trees growing in their native islands and to concentrate the whole production in the Amboyna Islands. With great difficulty the French succeeded in introducing the clove tree into Mauritius in the year 1770; subsequently the cultivation was introduced into Guiana, Brazil, most of the West Indian islands and Zanzibar. The chief commercial sources of supply were for a long time Zanzibar and its neighbouring island Pemba on the east African coast, but the competition of Java and Sumatra is severe and the synthetic production of eugenol (*see* below) has affected the trade. Madagascar is the principal source of the oil for the U.S. Imports in 1940 were 307,-

289 lb., of which Madagascar supplied more than 302,000 lb.

Cloves as they come into the market have a deep brown colour, a powerfully fragrant odour, and a hot acrid taste. When pressed they exude a volatile oil which is obtained as a commercial product by submitting the cloves with water to repeated distillation. This is, when new, a pale yellow or almost colourless fluid, becoming brown after some time; it possesses the odour and taste

FROM KÖHLER, "MEDIZINAL PFLANZEN"

BRANCH OF A CLOVE TREE SHOWING THE FLOWER BUDS WHICH, WHEN DRIED, MAKE THE CLOVES OF COMMERCE

peculiar to cloves. The essential oil of cloves—the *Oleum Caryophylli* of the British Pharmacopoeia—is a mixture of two substances. *Eugenol* or eugenic acid, $C_{10}H_{12}O_2$, is the chief constituent. Oil of cloves is soluble in alcohol and ether. Cloves are employed as a condiment in culinary operations, in confectionery, and in the preparation of *liqueurs*. In medicine they are tonic and carminative but they are little used except as adjuncts to other substances. The oil forms a convenient medium for using cloves for flavouring purposes, possesses the medicinal properties characteristic of a volatile oil, and is frequently employed to relieve toothache. Oil of cloves is regarded by many dental surgeons as the most effective local anaesthetic they possess. Clove oil must have a eugenol content of at least 82%.

CLOVIO, GIORGIO GIULIO (1498–1578), Italian painter of portraits and historical pieces, by birth a Croat and by profession a priest, is said to have studied at Rome under Giulio Romano, and at Verona under Girolamo de' Libri. His book of 26 pictures representing the procession of Corpus Domini, in Rome, was the work of nine years, and the covers were executed by Benvenuto Cellini. The British Museum has his twelve miniatures of the victories of the Emperor Charles V. In the Vatican library is preserved a manuscript life of Frederick, duke of Urbino, superbly illustrated by Clovio, who is *facile princeps* among Italian miniaturists. He was called Macedo, or Macedone, to connect him with his supposed Macedonian ancestry.

CLOVIS (*Chlodovech*) (*c.* 466–511), king of the Salian Franks, son of Childeric I., whom he succeeded in 481 at the age of 15. At that date the Salian Franks had advanced as far as the river Somme, and the centre of their power was at Tournai. On the history of Clovis between the years 481 and 486 the records are silent. In 486 he attacked Syagrius, a Roman general who, after the fall of the western empire in 476, had carved out for himself a principality south of the Somme, and is called by Gregory of Tours "rex Romanorum." After being defeated by Clovis at the battle of Soissons, Syagrius sought refuge with the Visigothic king Alaric II., who handed him over to the conqueror. Henceforth Clovis fixed his residence at Soissons, which was in the midst of public lands, *e.g.*, Berny-Rivière, Juvigny, etc. The episode of the vase of Soissons[1] has a legendary character, and all that it proves is the deference shown by the pagan king to the orthodox clergy. Clovis undoubtedly extended his dominion over the whole of Belgica Secunda, of which Reims was the capital, and conquered the neighbouring cities in detail. Little is known of the history of these conquests. It appears that St. Genevieve defended the town of Paris against Clovis for a long period, and that Verdun-sur-Meuse, after a brave stand, accepted an honourable capitulation thanks to St. Euspitius. In 491 some barbarian troops in the service of Rome, Arboruchi ('Αρμόρυχοι) Thuringians, and even Roman soldiers who could not return to Rome, went over to Clovis and swelled the ranks of his army.

In 493 Clovis married a Burgundian princess, Clotilda, niece of Gundobald and Godegesil, joint kings of Burgundy. This princess was a Christian, and earnestly desired the conversion of her husband. Although Clovis allowed his children to be baptized, he remained a pagan himself until the war against the Alamanni, who at the time occupied the country between the Vosges, and the Rhine and the neighbourhood of Lake Constance. By pushing their incursions westward they came into collision with Clovis, who marched against them and defeated them in the plain of the Rhine. The legend runs that, in the thickest of the fight, Clovis swore that he would be converted to the God of Clotilda if her God would grant him the victory. After subduing a part of the Alamanni, Clovis went to Reims, where he was baptized by St. Remigius on Christmas day 496, together with 3,000 Franks. The story of the phial of holy oil (the *Sainte Ampoule*) brought from heaven by a white dove for the baptism of Clovis was invented by archbishop Hincmar of Reims three centuries after the event.

The baptism of Clovis was an event of very great importance. From that time the orthodox Christians in the kingdom of the Burgundians and Visigoths looked to Clovis to deliver them from their Arian kings. Clovis seems to have failed in the case of Burgundy, which was at that time torn by the rivalry between Godegesil and his brother Gundobald. Godegesil appealed for help to Clovis, who defeated Gundobald on the banks of the Ouche near Dijon, and advanced as far as Avignon (500), but had to retire without being able to retain any of his conquests. Immediately after his departure Gundobald slew Godegesil at Vienne, and seized the whole of the Burgundian kingdom. Clovis was more fortunate in his war against the Visigoths. Having completed the subjugation of the Alamanni in 506, he marched against the Visigothic king Alaric II. in the following year, in spite of the efforts of Theodoric, king of the Ostrogoths, to prevent the war. After a decisive victory at Vouillé near Poitiers, in which Clovis slew Alaric with his own hand, the whole of the kingdom of the Visigoths as far as the Pyrenees was added to the Frankish empire, with the exception of Septimania, which, together with Spain, remained in possession of Alaric's grandson Amalaric, and Provence, which was seized by Theodoric and annexed to Italy. In 508 Clovis received at Tours the insignia of the consulship from the eastern emperor, Anastasius, but the title was purely honorific. The last years of his life Clovis spent in Paris, which he made the capital of his kingdom; here he built the church of the Holy Apostles, known later as the church of St. Geneviève. By murdering the petty Frankish kings who reigned at Cambrai, Cologne and other residences, he became sole king of all the Frankish tribes. He died in 511.

Clovis was the true founder of the Frankish monarchy. He reigned over the Salian Franks by hereditary right; over the other Frankish tribes by reason of his kinship with their kings and by the choice of the warriors, who raised him on the shield, and he governed the Gallo-Romans by right of conquest. He had the

[1] The story is as follows. The vase had been taken from a church by a Frankish soldier after the battle of Soissons, and the bishop had requested Clovis that it might be restored. But the soldier who had taken it refused to give it up, and broke it into fragments with his *francisca*, or battle-axe. Some time afterwards, when Clovis was reviewing his troops, he singled out the soldier who had broken the vase, upbraided him for the neglect of his arms, and dashed his *francisca* to the ground. As the man stooped to pick it up, the king clove his skull with the words "Thus didst thou serve the vase of Soissons."

Salic law drawn up, doubtless between the years 486 and 507, and seems to have been represented in the cities by a new functionary, the *graf, comes,* or count. He owed his success in great measure to his alliance with the church. He took the property of the church under his protection and in 511 convoked a council at Orléans, the canons of which have come down to us. But while protecting the church, he maintained his authority over it. He intervened in the nomination of bishops, and at the council of Orléans it was decided that no one, save a son of a priest, could be ordained clerk without the king's order or the permission of the count.

The chief source for the life of Clovis is the *Historia Francorum* (bk. ii) of Gregory of Tours, but it must be used with caution. Among modern works, *see* W. Junghans, *Die Geschichte der fränkischen Könige Childerich und Clodovech* (1857); F. Dahn, *Urgeschichte der germanischen und romanischen Völker,* vol. iii (1883); W. Schultze, *Deutsche Geschichte von der Urzeit bis zu den Karolingern,* vol. ii (1896); G. Kurth, Clovis (1901). (C. Pr.)

CLOVIS, a city of New Mexico, U.S., near the centre of the eastern boundary of the state; the county seat of Curry county. It is on federal highways 60, 70 and 84, and state highway 18 and is served by the Santa Fe railroad.

The population was 17,318 in 1950 and 10,065 in 1940 by the federal census. It is the state's most important livestock and dry farming area, with crops of wheat, sorghum grains, broomcorn, sudan, etc., and has large stockyards. Clovis was settled about 1907 and incorporated in 1908; in 1921 it adopted a commission form of government.

CLOWN, a rustic or boorish person; in pantomime, a comic character, always dressed in baggy costume, with face whitened and eccentrically lined with black and red paint. The character probably descends from representations of the devil in mediaeval miracle plays, developed through the fools or jesters of the Elizabethan drama. The whitened face and baggy costume indicate a connection also with the Pierrot of Italian comedy. The prominence of the clown in pantomime (*q.v.*) is a comparatively modern development as compared with that of Harlequin.

CLOYNE, small market town, County Cork, Ireland, 15 mi. E.S.E. of the city of Cork. Pop. (1951) 620. An ecclesiastical foundation of the 6th century, it has an ancient oratory and a cathedral (mainly 14th century) dedicated to St. Colman, disciple of St. Finbar of Cork. Opposite the cathedral is a fine round tower 100 ft. high. The town suffered from Scandinavian raids in the 9th century and was laid waste by Dermot O'Brian in 1071 and burned in 1137. In 1430 the bishopric was united to that of Cork, in 1638 it became independent, and in 1660 it was again united to Cork and Ross. It became independent once more in 1678 and so continued until its reunion with Cork in 1835. The name *Cluain-Uamha* signifies "the meadow of the cave," from the limestone caves of the vicinity. The Pipe Roll of Cloyne compiled by Bishop Swaffham in 1364 is a valuable record of mediaeval land tenure. It is now in the record office, Dublin, and was edited by Caulfield in 1859. The cathedral contains a memorial to Bishop George Berkeley, the philosopher (1685–1753). The town gives its name also to a Roman Catholic diocese with a cathedral at Cobh.

CLUBFOOT. Clubfoot is the name given a deformity of the foot and ankle resulting in abnormal position and shape of the foot. The deformity is present at birth. In the more severe examples three distinct components of the deformity may be recognized, but in milder cases one or another of these may be lacking. The most constant component is plantar flexion of the foot at the ankle so that the foot points downward. Next most common is inversion of the foot, which is a rolling in of the sole of the foot so that the soles of the feet face each other. The third component is adduction of the fore foot, which is an extreme pigeon-toe deformity. The Latin name given these deformities is *talipes equinovarus.* All of these deformities are rigidly maintained so that the foot may not be returned to normal position. Each of the deformities may be present in varying degrees from mild to severe.

At an early age these deformities result from abnormal pull of tendons and contracture of the ligaments, but over a period of years and particularly after weight bearing, bony deformity may appear preventing correction of the deformities. In approximately half of the patients, both feet are involved.

The cause of clubfoot is essentially unknown. Many theories have been advocated, but none has been proved. The most popular theories are increased pressure or faulty position in the uterus and hereditary influences. None of these theories has any foundation in experimental evidence. In observations on animals, typical clubfoot deformities in the offspring have been produced by excessive exposure to X-rays of a pregnant animal or by vitamin-deficient diets given a pregnant animal.

Treatment of the clubfoot depends upon the severity and multiplicity of the deformities. The treatment should begin early in infancy when the tissues are more pliable and before bony deformity occurs. In the extremely mild deformity, whether of plantar flexion, inversion or adduction of the fore foot, simple manipulation by the physician or the parent may suffice. In the more severe deformities, splints, plaster of Paris casts or special shoes may be necessary. Numerous methods of application of the splints and casts have been devised, but all depend upon the reversal of the deformities at an early age so that the muscles, tendons and bones may grow normally.

More severe or untreated deformities may require surgery upon tendons or bones or both. Treatment must be continued until all component deformities are corrected. Following adequate and complete correction, observation of the person must be continued until growth ceases. This is necessary because of the tendency toward recurrence of these deformities when the child is passing through a period of rapid growth. With adequate treatment started early in infancy, the patient should be able to lead a normal life with normal activity.

Frequently, similar deformities of the feet follow poliomyelitis or other diseases. In these instances, braces and surgery may be required because of muscle weakness or fixed deformity.

Abnormalities opposite to those of clubfoot frequently occur. These include increased dorsiflexion of the foot so that the foot points upward rather than downward, and eversion of the foot so that the sole faces outward. These deformities are usually more flexible than those of clubfoot and are more amenable to simple methods of treatment.

Kite, "Principles Involved in the Treatment of Congenital Club Foot," *Jour. of Bone and Joint Surgery,* vol. 21, pp. 595–606 (1939); Philip Lewin, *The Foot and Ankle* (Philadelphia, London, 1941); Walter Mercer, *Orthopaedic Surgery* 4th ed. (London, Baltimore, 1950). (J. S. Ms.)

CLUB-MOSS, the common name for plants of the genus *Lycopodium,* and often extended to cover all the Lycopodiales, which form one of the main divisions of the Pteridophyta (*q.v.*), a group which also includes the ferns. Club-mosses are also called staghorn-mosses.

CLUBS. The ancient Greek *hetaireia* and the Roman *sodalitas* may be regarded as the earliest ancestors of the modern club, although they were in fact loose associations of like-minded companions rather than true clubs, as we understand that term. Among the Greeks the religious organizations devoted to the worship of esoteric deities not recognized by the state religion, were the most important, but political, commercial and athletic associations also flourished, together with social dining clubs whose members gathered to eat together and exchange ideas.

In Rome religious and trade clubs were common, but these, like their Greek predecessors, were more like sects or trade guilds than anything we should now call a club. The Roman political clubs were rather more like modern ones in aim and organization, but they tended to degenerate into unruly cabals and were suppressed by Julius Caesar as dangerous to public order. Burial clubs existed among the poorer people who might otherwise have been unable to afford for their dead the expensive funeral rites then considered necessary (see *Rural Clubs* below).

Cicero in *De Senectute* mentions *symposia* which, he says, he enjoyed as much for the opportunities of talking they afforded

him as for their well-cooked meals. Though some of these early societies elected committees and officers, and a few, like one mentioned by Justus Lipsius, drew up definite rules, they had little in common with the modern club; and it is probable that the true club spirit was then most easily found in the unorganized but more or less regular gatherings of friends in the ease and comfort of the public baths.

BRITISH CLUBS

The Rise of English Clubs.—The earliest English club of which there is certain knowledge was Le Court de Bone Compagnie, described in a poem by Thomas Hoccleve, who was a member. It flourished in Henry IV's reign and was evidently a dining club which held its dinners in a house near the Middle Temple, London. The Elizabethan Friday Street or Bread Street club was also a dining association, which met in the famous Mermaid tavern, and is traditionally said to have been founded by Sir Walter Raleigh. About 1616 the Apollo club was founded by Ben Jonson in the Devil tavern by Temple Bar. Many of the most distinguished men of the time were among its members, including Lucius Carey, Sir John Suckling, Robert Herrick, and Lord Herbert of Cherbury. Though purely masculine in its membership, this club adopted the modern-seeming custom of admitting ladies on special nights.

With the rise of coffeehouses in the mid-17th century, clubs acquired more or less settled homes and began to take on distinctive character. It was usual for the landlord of a coffeehouse to allot a special room for the club's use. For this he made no charge, relying for his profit on the food and drink consumed by members and the distinction conferred upon his house by the presence therein of notable men. It was at this period that the term "club," in its modern sense, first came into common use. "We now," says John Aubrey, "use the word clubbe for a sodality in a taverne," and Samuel Pepys, in his diary for 1660, mentions Woods' tavern in Pall Mall where he and his friends used to go "for clubbing."

Among the most notable political clubs of the 17th century was the Rota, founded by James Harrington in 1659. This was strongly republican in sentiment, and included among its members Lord Algernon Sidney and Lord William Russell, both of whom were subsequently executed for their part in the Rye House plot, Sir William Petty and Andrew Marvell, the poet. Pepys calls it the Coffee club, perhaps because it met in Miles' coffeehouse in Westminster. The Sealed Knot was a royalist association, while the Green Ribbon club (sometimes called the King's Head club from the Chancery lane tavern in which it met) was an organization of influential malcontents under the leadership of Lord Shaftesbury. In 1693 White's, which in the 18th century was to become a prominent Tory stronghold, began its long career in the chocolate house owned by and named after Francis White. In its beginnings it was social rather than political and derived its clublike characteristics from White's determination to keep his clientele select and from the strict rules he enforced. The original chocolate house stood in St. James's street, on the site of the present Boodle's. In 1697 the business was transferred to the opposite side of the road where it was later carried on by John Arthur, the founder in 1765 of the club known as Arthur's. In 1736 White's became a private club, and 19 years later it moved to its modern site in St. James's street.

Of the nonpolitical Stuart clubs the best known are the Royal Navy (1674), prototype of the service clubs which sprang up in the 19th century; the Civil (1699), forerunner of the City of London (1832); and the Wednesday, founded by William Paterson in the Dog and Whistle tavern. Friday street. Paterson was the financial genius of his age, and it was at the weekly meetings over which he presided that the project which ultimately resulted in the creation of the Bank of England was first evolved.

The 18th-Century Clubs.—In the 18th century the number and variety of clubs increased very rapidly. Many were comparatively short-lived and eccentric associations, reflecting the more violent phases of contemporary political feeling, or the extravagant, and often lawless, fancies of idle young men. Among these were the Calves Head club, established shortly after the execution of Charles I; the chief meetings were held on the anniversaries of the execution, when dishes served to members included calves' heads, to represent the king and his adherents, and a pike, to represent tyranny. Others were the various Mug House clubs, most of which were eventually suppressed by the authorities because of their disorderly conduct; the notorious Hell Fire club at Medmenham, and the Mohocks', whose unruly members terrorized law-abiding Londoners by their insulting and violent behaviour. Other societies with odd, and sometimes unedifying, aims are mentioned in the pages of the Spectator, and in Ned Ward's two books on club life. It is true that Ward often drew upon his imagination in his accounts, but the clubs he described were usually based upon existing coteries.

Among the more respectable of these ephemeral organizations may be mentioned the No Pay No Liquor club, whose members were obliged to wear hats of peculiar fashion, and to drink from a cup of peculiar shape, the Je ne sçai quoi, of which the prince of Wales was perpetual chairman, and the so-called street clubs. These were associations formed in particular London streets whose residents, afraid to venture far at night because of Mohocks and footpads, started their own small clubs in coffeehouses or taverns near their homes.

Of the more serious clubs, many were political, or partly so. The October (of which the March Primitive October was a more extreme offshoot) was founded in 1710 or 1711 by a band of Tories dissatisfied with Robert Harley's administration. The Cocoa Tree began as a Jacobite association meeting at the chocolate house of that name and became a private club in 1746. Jonathan Swift was a leading member of both these, as he was of the Saturday, founded by Henry St. John in 1711, the short-lived Brothers, and the Jacobite Mourning Bush, afterward called the Fountain. Other mainly political clubs of the time were: the Hanover, for the more ardent supporters of the new dynasty; the Rumpsteak or Liberty (1734); the Board, mentioned by Horace Walpole in a letter dated 1743; the later Revolution and Independents; White's, which became definitely Tory under William Pitt's influence in 1783; and its Whig opposite number, Brooks's. The last-named was founded in 1764 as a social and gaming establishment by William Macall, who bought a house in Pall Mall and, transposing the letters of his name, called it Almack's. This club (not to be confused with the more famous Almack's assembly rooms in King street, also run by Macall) was bought by Brooks in 1774. Four years later it was transferred to the modern club house in St. James's street, then newly erected by Henry Holland, and thereafter was always known as Brooks's. Renowned for its high stakes in play and its social brilliance, it was also famous as a leading Whig stronghold and the favourite haunt of Charles James Fox and his associates.

Important and influential as were the political clubs of the 18th century, it was really the literary, artistic and social associations which were the most characteristic of the period. Many clubs combined these attributes. The members of Brooks's assumed the role of arbiters of literary taste; those of the Blue Stocking moved with equal ease in the learned and aristocratic worlds. The Scriblerus club, founded by Swift in 1714, included men of fashion like the earl of Oxford and Viscount Bolingbroke, and poets like Alexander Pope and John Gay. The Society of Dilettanti (1734) was a gathering of amateur art collectors, whose fine collection of pictures by Sir Joshua Reynolds and Francis Knapton is housed in the St. James's club, Piccadilly, where the Dilettanti hold their dinners. The famous Kit Kat club, founded at the beginning of the century by Joseph Tonson, a bookseller, was a literary association in its inception, but it soon became renowned at once for its distinguished membership, its toasts and the portraits of members painted by Sir Godfrey Kneller. The name was derived from Christopher Cat, in whose eating house the first literary reunions were held. In 1749 Dr. Johnson who, like Swift, was an ardent clubman, founded the Ivy Lane club at the King's Head tavern in that thoroughfare. Fifteen years later he and Sir Joshua Reynolds together organized the more celebrated Literary club, usually known simply as the "The Club." The original membership was limited to 12 and gradually increased to 40, after which

a resolution was passed in 1780 that it should never exceed that number. Oliver Goldsmith, Edmund Burke, David Garrick, James Boswell and Sir John Hawkins were among the members in the early years, and during the subsequent two centuries of this famous club's existence, many of the outstanding men of each generation joined it. In 1783, not long before his death, Johnson founded yet another club, the Essex Head, so called from the tavern near the Strand in which it met.

Among associations with rather more specialized aims was the Royal Society club, a scientific body founded in 1743, and not to be confused with the modern Royal Societies club, which was not formed until 1894; the Noviomagians, which was antiquarian; the Robin Hood, a debating society which came into prominence when Edmund Burke joined it; and such semidebating, semisocial organizations as Cogers in Fleet street, Goldsmith's Wednesday club, the Clifford Street club, and the King of Clubs, founded in 1801.

Boodle's (1763) which, like White's and Brooks's, still occupies its 18th-century home, was one of the more famous social institutions. Originally called the Sçavoir Vivre, it was later renamed after William Boodle, who became its manager about 11 years after its foundation. This club was renowned for its cuisine. Its beautiful clubhouse in St. James's street is usually said to have been designed by the Adam brothers. Another fine building which, after some vicissitudes returned to the club world is Coventry house, Piccadilly, once the home of the Coventry House club (1757) which settled there in 1769, and now occupied by the social and diplomatic St. James's club (1857). The Sublime Society of Beefsteaks, of which the modern Beefsteak club (1876) is in some sense the successor, came into being in 1735. Besides these there was Arthur's (1765), noted for its Wiltshire connections and its veal *à la royale;* the Dover House club (1787), usually known as Weltzie's, from the name of its founder, a former servant of the prince of Wales; Graham's, a noted gaming club in St. James's street; the Wittanagemot, which appears to have been a select dining club; and a number of subsidiary clubs meeting at Will's or Tom's coffeehouses, which John Macky has described in his *Journey through England.*

Influence Abroad.—It was at this period that the club, hitherto an almost entirely British institution, crossed the English channel and the Atlantic. Clubs of the English pattern appeared in French and German taverns. In Berlin the literary Monday club was founded in 1749. Three years later the first purely social club in Germany was inaugurated. It was followed by a variety of political clubs, many of which were suppressed in 1848. In France small political coteries abounded in the years immediately preceding the French Revolution, and contributed largely to the unrest of the time.

In America the club system does not seem to have been adopted before the Declaration of Independence, the earliest genuine club there of which we have record being the Hoboken Turtle, established in 1797. Such pioneers were, however, the first swallows of an abundant summer, and today clubs of all kinds are to be found in every country inhabited by Europeans and Americans. (*See* also below.)

Clubs of the 19th and 20th Centuries.—In the 19th century clubs in general began to follow the lead of White's and Brooks's, and to acquire permanent headquarters, often in the form of imposing houses specially built for them by well-known architects. They also tended to become more specialized. Whereas formerly statesmen and soldiers, poets, artists, scientists and men of fashion had met in common centres, clubs specially formed for different professions and interests now became usual. This differentiation first appeared in the service clubs. At the end of the Napoleonic Wars many officers of both services returned to London and needed meeting places where they could share meals and reminiscences. In 1813 the Guards club was formed, and in 1815 the United Service. The Junior United Service was founded in 1827 and the Army and Navy club ten years later. In due course these pioneers were followed by the Naval and Military (1862), the Cavalry Club (1890), the Junior Army and Navy (1911) and the Royal Air Force (1917). The soldiers and officials of the East India company congregated chiefly at the Oriental (1824) and the East India United Service (1850).

Among civilian specialized clubs, the City of London (1832) and Gresham's (1843) were and remained mainly for merchants and bankers, as the Farmers' (1842) was and is for agriculturists. The Garrick, founded in 1831, was one of the earlier theatrical foundations (a still earlier example was the Thespian, which flourished in the second half of the 18th century), and it was followed by the Green Room (1877), the Rehearsal (1892), the O-P. club (1900) and the Vaudeville (1901), to name only a few.

Of the many literary and artistic clubs founded in the 19th century, the most important was undoubtedly the Athenaeum, inaugurated in 1823 by John Wilson Croker at John Murray's house in Albemarle street. This famous club, to which Sir Walter Scott, Tom Moore and most of the leading writers of that and later days belonged, was first known as the Society. In its early years it met in Waterloo place, but moved in 1830 to the present clubhouse in Pall Mall, designed for it by Decimus Burton.

Almost as well-known are the Savile (1868), once called the New club, and generally regarded as a waiting place for the Athenaeum, and the Savage, founded in 1857 and noted for its early bohemianism. The Arts club came into being in 1863, the Authors in 1891, and the later P.E.N. club in 1921. The principal university clubs were also formed during the 19th century, the United University and the New University in 1822, the Oxford and Cambridge in 1830, the New Oxford and Cambridge in 1883, and the City University in 1885.

Of the 19th-century political clubs, other than White's and Brooks's, already formed and still in existence, the two outstanding foundations are the Conservative Carlton club (1831) and the Liberal Reform club (1834). Both these occupy houses of considerable architectural importance, that of the Reform being usually considered the most impressive of its kind in London. They were followed by numerous others: the Conservative (1840); the Junior Carlton (1864); the Cobden (1866); St. Stephen's (1870); the Eighty (1880); the National Liberal (1882); the Constitutional (1883); and the United (1890). These were all West End clubs, the City having its own political organizations, such as the City Carlton (1868), the City Liberal and various others.

The passion for gambling which marked the latter half of the 18th century continued during the first years of the 19th in most of the older social clubs and in some new ones. In 1806 Watier's club was founded in Bolton street and rapidly became the foremost gambling club in London. Beau Brummell was one of its prominent members. The pace was rather too rapid even for the hardened gamblers of the Regency period, and after a feverish existence of little more than 12 years, Watier's perished in 1819. What remained of it was then acquired by William Crockford who in 1828 opened the gambling club named after him. Crockford's was housed in a magnificent building in St. James's street, designed by James Wyatt, which became the home of the Devonshire club (1875). Hazard, whist, and card games of all sorts were its principal attractions, but it was also renowned for its excellent meals and for cockfights held in a small cockpit in the basement. Like Watier's, it was short-lived and broke up soon after its founder's death in 1844.

Among the other fashionable clubs of the first half of the 19th century was the Union, founded in 1804; the Alfred (1808), of which Lord Byron and George Canning were members, and which the wits nicknamed the Half-read; the Travellers, a diplomatic club founded in 1819 by Lord Castlereagh; and the Windham, started by Baron Nugent in 1828. Later came the Thatched House (1865), the Bachelors' (1881), the Wellington (1885) and many others.

Besides the clubs having their own premises, there were various dining clubs inaugurated to do honour to some great man, such as Dr. Johnson, Pepys, Samuel Butler or Charles Dickens, or to provide regular meetings for collectors or individuals interested in particular objects and ideas. Grillion's, to which so many illustrious men belonged, was founded in 1813 by Sir Thomas Acland as a centre for men of all shades of political feeling. The

Cosmopolitan (1852) and the Breakfast club (1866) were similar nonparty institutions, whose members met for dinner and breakfast respectively. There were also the Boz and the Erewhon for Dickens and Butler enthusiasts, the Titmarsh, the Roxburghe, for book-collectors, the First Edition, the Sette of Odde Volumes, the Hardwicke with legal interests, the Urban and others too numerous to mention.

Women's Clubs.—The last years of the Victorian era also saw the rise of women's clubs. An organization known as the Ladies club and referred to by Walpole as "the female Almack's," existed in the 18th century. There were also associations of working women at this period, such as the Mantua-makers' club in St. Martin's lane and the Milliners' club near the Royal Exchange. In general, however, clubs were exclusively masculine institutions until 1883, when the Alexandria was founded. No man was allowed to enter its premises, and on one occasion even the prince of Wales (afterward Edward VII) was refused admittance when he called for the princess. The University Women's club was formed in 1887, the Pioneer in 1892.

Three years later the American Women's club for Americans visiting London came into being, and in 1897 the Empress. Once the idea of such associations was accepted, women's clubs developed with great rapidity. The Ladies' Empire was founded in 1902, the London Lyceum in 1904, the Ladies' Carlton in 1906. Thereafter every sort of social, literary, artistic, sporting and political interest had its women's clubs in London and the provinces, and there are also many institutions like the Pilot club (1949), the Lansdowne (1935) and the International Sportsmen (1929) and others, with both male and female members.

Sports Clubs.—The love of sport has been responsible for numerous clubs, from the Tudor companies of young men with grandiloquent titles like Prince Arthur's Knights, down to the foundations of our own day. Among 18th-century clubs of this type may be mentioned the Sons of the Thames, predecessor of the Thames Rowing club (1860) and the London Rowing club (1856); the Royal Thames Yacht club, founded in 1775; the Royal Toxopholite (1781); the coaching Four-in-Hand; and the famous Hambledon club, started about the middle of the century, whose members laid the foundations of modern cricket. The last-named was dissolved in 1791, but its place was taken by the Marylebone Cricket club (1787), the famous M.C.C.

About 1750 a number of men interested in horse racing began meeting at the Star and Garter coffee house in Pall Mall, and there founded an association to regulate racing and eliminate abuses at Newmarket. This was the Jockey club. Its influence soon spread from Newmarket to other courses, and it became the ruling authority in English racing throughout the country. Other clubs connected with the same sport are the Turf, which developed from the earlier Arlington in 1868, and various clubs connected with particular courses, such as the Hurst Park, the Kempton Park and the Sandown.

Clubs representing every branch of sport were established in London and the provinces, and some, like the Sports club (1893), the United Sports (1903) the Bath club and others, embrace more than one form. Among the specialized clubs may be mentioned the National Sporting club, devoted to boxing; the hunting Badminton and Beaufort; the Golfers and the Lady Golfers; the Flyfishers (1884); the London Fencing club (1848) and the Sword (1905); the Alpine (1857) and the Ladies' Alpine (1907); and the Kennel club (1873). Aquatic organizations range from the Royal Yacht Squadron at Cowes (1815) and the Royal Ocean Racing club (1925) to the model yacht racing clubs associated with the Round pond in Kensington Gardens.

Others represent the newer forms of sport, such as the Royal Automobile club (1897), whose club house is among the most luxurious in London, and the Royal Aero club (1901).

Rural Clubs.—Rural benefit clubs formed an important part of village life from the late years of the 18th century until the introduction of national insurance in 1912. The members paid a monthly contribution of 2 *s.* or more, and the money so collected was used to pay sickness and unemployment benefit, and a lump sum to the survivor on the death of a member or his wife. Regular meetings were held in a room specially set apart in the local inn, and once a year, in summer, there was the club day. This included a service in the parish church, with a sermon, a procession with banners and a band, sports, dances and a dinner at the inn. In many parishes there were more than one club; and in a few there was also a female club, which had its own funds and yearly procession, and met independently of the men. In their early years the benefit clubs were purely local institutions, but with the growth of the great friendly societies, they often became branches of such societies, while still retaining their local character and customs, including, in many cases, ceremonial forms of admission. With the introduction of national insurance, most village clubs were given up, but a few continued to flourish and carry on their work. The Greyhound club at Marsh Gibbon, founded in 1788, is one of those which still pays benefit to its members and has its annual gathering on Oak Apple day (May 29), and others survive in Dorset, Hampshire and elsewhere.

Club Organization.—The internal economy of clubs varies as much as does the character of the aims of such associations, or the nature and architectural features of their clubhouses. In some the committee possesses the power of election and the corresponding power of refusal; in others this is by ballot of members. Some, like the Athenaeum, have the right of electing annually a certain number of members on account of their distinguished eminence, services to the state, literature, art, science and so forth. The committee is, of course, the responsible body, but in most cases the actual running of the club is largely in the hands of the secretary, control by members being exercised through the annual general meeting.

Clubs are also subject to certain legal restrictions and duties. Since the Licensing act of 1902 (passed primarily to prevent clubs being formed merely as a cloak for the sale of intoxicants), every club, large or small, has annually to provide the authorities with information concerning its membership, subscription and general conduct. The details of the laws covering club management may be conveniently studied in J. Wertheimer's *Law Relating to Clubs*, (5th ed. by Maxwell Turner and A. S. Wilson, London, 1935). (*See* also WORKING MEN'S CLUBS.)

UNITED STATES

The number and variety of clubs in the United States demonstrate the prevalence of "joining" among the American people. As distinguished from many other expressions of this voluntary associationalism, clubs usually place greater stress upon sociability and are more apt to be local in nature than chapters of national organizations.

Although U.S. clubs derive from English prototypes of the late 17th and early 18th centuries, their appearance was understandably belated. The colonial period lacked both the city life and the leisure necessary for their development. Nevertheless, as early as the mid-18th century the success of Benjamin Franklin's

Junto in Philadelphia, Pa., and the spread of Masonic lodges suggested that associational activity would presently become a prominent part of American life. Urban growth in the late 19th century not only made clubs possible by assembling groups large enough for specialized interests of nearly every sort but also made clubs essential to provide adequate social outlets in the impersonal metropolis.

The most direct imitations of English clubs (see *British Clubs* above) are the socially exclusive gentlemen's clubs existing in most large cities, such as the Somerset club of Boston, Mass., and the Pacific Union club of San Francisco, Calif. Admitting only those of high social and financial standing, they usually have fine buildings with eating, drinking, reading and athletic facilities. Other clubs, while highly selective, make some form of literary, artistic or intellectual interest the basis for affiliation rather than wealth or social background. In differing ways the Lambs and Players clubs of New York city, the Cosmos club of Washington, D.C., and the Bohemian club of San Francisco could be placed in this category. Slightly different are the large number of luncheon and dinner clubs, usually composed of business and professional men, which may or may not have their own buildings. Although the social element also predominates in these, they are often basically discussion groups which do little more than meet periodically for that purpose.

All the clubs mentioned tend to be highly restrictive in membership, but there are also many organizations open to all individuals sharing a mutual interest. Ever since the rise of "Democratic societies" among the opponents of the Federalist administration in the 1790s, political clubs have been prominent examples of this type. A vast network of such groups now forms the basis of U.S. political parties, at the same time affording considerable social opportunities for their members. In the late 19th century, when ward clubs in large cities became identified in some minds with corrupt political machines, good government advocates began founding the modern City clubs and Commonwealth clubs, which are largely devoted to the study of public affairs and the improvement of government. In addition to these groups, which also often have their own buildings, innumerable less pretentious civic clubs developed in smaller communities or even neighbourhoods throughout the country. The average businessman, however, has preferred to join one of the service clubs such as the Rotary, Exchange, Kiwanis or Lions clubs. Good fellowship is one of their main attractions, and they sponsor many worthwhile programs to serve community welfare.

With the steady decline of working hours in the 20th century, came the existence and even the problem of far more leisure time for large numbers of people. Not surprisingly organizations have appeared catering to recreational interests of almost every description. In particular, because of the restrictions of urban life, a wide variety of athletic clubs arose. Golf clubs, for example, appeared in or near every metropolitan area. In the form of elaborate country clubs, many furnish additional facilities which make them among the few clubs that serve the entire family unit. With their restaurants, bars and Saturday night dances, they increasingly became the social centres for well-to-do suburban residents; thus the term "country club set" became part of the American vocabulary.

In addition to clubs in which the emphasis is on social exclusiveness, civic activity or avocational interests, many neighbourhood clubs have been formed along national or religious lines. There are still many survivals of the social clubs formed by various immigrant groups, and nearly every large American religious denomination has affiliated clubs that are important in the social as well as religious lives of their adherents.

The form of club life most characteristic of the United States, however, is the women's club, a striking demonstration of the leisure that has become available, at least to the urban middle-class woman. Organizations like the Chilton club, in Boston, the Colony club in New York city, and the Acorn club in Philadelphia parallel the exclusive men's groups, but far more significant are the numerous women's clubs of general membership which, beginning with the New England Women's club of Boston and the Sorosis of New York (both founded in 1868), spread so rapidly that by 1889 the General Federation of Women's Clubs was formed. At first concentrating on subjects such as literature, art and gardening, they extended their interests to include social problems and public affairs until the American clubwoman became a far more representative figure than the clubman.

There are, of course, numerous organized clubs for children in the United States, such as the Boy Scouts, Girl Scouts and, in rural areas, the 4-H clubs (*qq.v.*). (WE. E. D.)

CLUE or CLEW, the thread of life, which, according to the fable, the fates spin for every man (O.E. *cluwe*, a ball of thread). The figurative meaning, a piece of evidence leading to discovery, is derived from the story of Theseus, who was guided through the labyrinth by the ball of thread held by Ariadne.

CLUENTIUS HABITUS, AULUS, of Larinum in Samnium, the hero of a Roman *cause célèbre*. In 74 B.C. he accused his step-father Statius Albius Oppianicus of an attempt to poison him, and Oppianicus was condemned. But there had been bribery; Cluentius was degraded, and in 66 charged with having caused his step-father to be poisoned. Cicero defended Cluentius, who was acquitted. The speech is considered one of Cicero's best and is more quoted by Quintilian than any other.

See Quintilian, *Inst.*, ii, 17, 21. Editions of the speech by W. Peterson (1899), W. Ramsay (1883); *see* also H. Nettleship, *Lectures and Essays* (1885).

CLUJ (Ger. Klausenburg; Hung. Kolozsvár), a city of Transylvania, capital of the department of Cluj, and formerly of the principality of Transylvania. Pop. (1948) 117,915, mostly Magyars, Rumanians and Jews. Cluj lies mainly on the right bank of the Somos Mic, among considerable hills. On the left bank is the "Bridge Suburb" and the citadel. The streets have a modern appearance. In the central square is the fine Gothic church of St. Michael (1396–1432), and in front of it a statue of Matthias Corvinus (1902). One side of the square is formed by the Batthanyi palace, formerly of the princes of Transylvania. Other noteworthy buildings are the Reformed church, built by Matthias Corvinus in 1486 and ceded to the Calvinists by Gabriel Bethlen in 1662, containing the coats of arms of the old Hungarian dominant families, the house in which Matthias Corvinus was born (1443), now an ethnographical museum, and many palaces of the Hungarian nobility. Cluj is an orthodox bishopric, also a bishopric of the Reformed and Uniate Churches; and possesses a university, a court of appeal, a theatre, opera and several museums. Its industry includes textile, paper, sugar, candle, soap and earthenware factories, breweries and distilleries.

Cluj is believed to occupy the site of a Roman settlement named Napoca. It was colonized by Saxons in 1178, and at first enjoyed many privileges and great prosperity; but many Saxons left it in the 16th century in consequence of the introduction of Uniate doctrine, and it presently became the centre of the Magyar element in Transylvania. It was capital of Transylvania and seat of the Transylvanian diets.

Cluj, coveted by Hungary since World War I, was ceded to that country by Rumania Aug. 30, 1940, by the award of Vienna. This award was dictated by Germany and Italy.

CLUMP, a lump, group or cluster, *e.g.*, of trees. A clumsy shoe worn by German peasants, made from a single piece of wood; the thick extra sole added to heavy boots for rough wear. Shoemakers speak of clumping a boot when a new sole is nailed, not sewn by hand, to the old sole.

CLUNES, a borough of Talbot county, Victoria, Australia, 97½ mi. by rail N.W. of Melbourne. Pop. (1954) 968. It is the centre of an agricultural, pastoral and mining district, in which gold was first discovered in 1851. It is at an elevation of 1,081 ft. An annual agricultural exhibition is held in the town.

CLUNY or CLUGNY, a town of east central France, in the department of Saône-et-Loire, on the left bank of the Grosne, 14 mi. N.W. of Mâcon. Pop. (1946) 4,046. The interest of the town lies in its specimens of mediaeval architecture, which include, besides its celebrated abbey, the Gothic church of Nôtre-Dame, the church of St. Marcel with its beautiful Romanesque spire, portions of the ancient fortifications and a number of old houses. Cluny

gradually increased in importance with the founding of the abbey (910) and the development of the religious fraternity, and in 1090 received a communal charter from the abbot St. Hugh. In 1471 the town was taken by the troops of Louis XI. In 1529 the abbey was given "in commendam" to the family of Guise. The town and abbey suffered during the Wars of Religion of the 16th century, and the abbey was closed in 1790.

The chief remains of the abbey are the ruins of the basilica of St. Peter and the abbot's palace. The church was a Romanesque building, completed early in the 12th century, and until the erection of St. Peter at Rome was the largest ecclesiastical building in Europe. It was in great part demolished under the First Empire, but the south transept, a high octagonal tower, the chapel of Bourbon (15th century), and the ruins of the apse still remain. In 1750 the abbey buildings were largely rebuilt. The abbot's palace (15th century) serves as *hôtel-de-ville,* library and museum. The town has quarries of limestone and building-stone, and manufactures pottery, leather and paper.

The Order of Cluniac Benedictines.—The Monastery of Cluny was founded in 910 by William I. the Pious, count of Auvergne and duke of Guienne (Aquitaine). The first abbot was Berno, who had under his rule two monasteries in the neighbourhood. Before his death in 927 two or three more came under his control, so that he bequeathed to his successor the government of a little group of five or six houses, which became the nucleus of the order of Cluny. Berno's successor was Odo: armed with papal privileges he set to work to make Cluny the centre of a revival and reform among the monasteries of France; he also journeyed to Italy, and induced some of the great Benedictine houses (*see* BENEDICTINES), and among them St. Benedict's own monasteries of Subiaco and Monte Cassino, to receive the reform and adopt the Cluny manner of life. The process of extension, partly by founding new houses, partly by incorporating old ones, went on under Odo's successors, so that by the middle of the 12th century Cluny had become the centre and head of a great order embracing 314 monasteries—the number 2,000, sometimes given, is an exaggeration—in all parts of Europe, in France, Italy, the Empire, Lorraine, Spain, England, Scotland, Poland, and even in the Holy Land. And the influence of Cluny extended far beyond the actual order: many monasteries besides Monte Cassino and Subiaco adopted its customs and manner of life without subjecting themselves to its sway. Fleury and Hirsau may be mentioned as conspicuous examples.

If its influence on the subsequent history of monastic and religious life and organization be considered, the most noteworthy feature of the Cluny system was its external polity, which constituted it a veritable "order" in the modern sense of the word, the first that had existed since that of Pachomius (*see* MONASTICISM). All the houses that belonged, either by foundation or incorporation, to the Cluny system were absolutely subject to Cluny and its abbot, who was "general" in the same sense as the general of the Jesuits or Dominicans, the practically absolute ruler of the whole system. The superiors of all the subject houses (usually priors, not abbots) were his nominees; every member of the order was professed by his permission, and had to pass some of the early years of his monastic life at Cluny itself; the abbot of Cluny had entire control over every one of the monks—some 10,000, it is said; it even came about that he had the practical appointment of his successor. For a description and criticism of the system, *see* F. A. Gasquet, *Sketch of Monastic Constitutional History,* pp. xxxii.–xxxv. (the Introduction to 2nd ed. [1895] of the English trans. of the *Monks of the West*); here it must suffice to say that it is the very antithesis of the Benedictine polity.

The greatness of Cluny is really the greatness of its early abbots. If the short reign of the unworthy Pontius be excepted, Cluny was ruled during a period of about 250 years (910–1157) by a succession of seven great abbots, who combined those high qualities of character, ability and religion that were necessary for so commanding a position; they were Berno, Odo, Aymard, Majolus (Maieul), Odilo, Hugh, Peter the Venerable. Sprung from noble families of the neighbourhood; educated to the highest level of the culture of those times; taking part in all great movements of ecclesiastical and temporal politics; refusing the first sees in Western Christendom, the cardinalate, and the papacy itself, they ever remained true to their state as monks, without loss of piety or religion. Four of them, indeed, Odo, Maieul, Odilo and Hugh, are venerated as saints.

In the movement associated with the name of Hildebrand the influence of Cluny was thrown strongly on the side of religious and ecclesiastical reform, as in the suppression of simony and the enforcing of clerical celibacy; but in the struggle between the papacy and the Empire the abbots of Cluny seem to have exercised a moderating influence. Hildebrand himself, though probably not a monk of Cluny, was a monk of a Cluniac monastery in Rome; his successor, Urban II., was actually a Cluny monk, as was Paschal II. It may safely be said that from the middle of the 10th century until the middle of the 12th, Cluny was the chief centre of religious influence throughout Western Europe, and the abbot of Cluny, next to the pope, the most important and powerful ecclesiastic in the Latin Church.

During the abbacy of Peter the Venerable (1122–1157) it became clear that, after a lapse of two centuries, a renewal of the framework of the life and a revival of its spirit had become necessary. Accordingly he summoned a great chapter of the whole order whereat the priors and representatives of the subject houses attended in such numbers that, along with the Cluny community, the assembly consisted of 1,200 monks. This chapter drew up the 76 statutes associated with Peter's name, regulating the whole range of claustral life, and solemnly promulgated as binding on the whole Cluniac obedience. But these measures did not succeed in saving Cluny from a rapid decline that set in immediately after Peter's death. The rise of the Cistercians and the mendicant orders were contributory causes, and also the difficulties experienced in keeping houses in other countries subject to a French superior. And so the great system gradually became a mere congregation of French houses, which was dissolved in 1790.

Cluniac houses were introduced into England under the Conqueror. The first foundation was at Barnstaple; the second at Lewes by William de Warenne, in 1077, and it counted as one of the "Five Daughters of Cluny." Though the bonds with Cluny seem to have been much relaxed if not wholly broken, the Cluniac houses continued as a separate group up to the dissolution, never taking part in the chapters of the English Benedictines.

Abridged accounts, with references to the most recent literature, may be found in Heimbucher, *Orden und Kongregationen* (1896), i. § 20; Herzog-Hauck, *Realencyklopädie* (ed. 3), art. "Cluni" (Grutzmacher); and the *Catholic Encyclopaedia, art.* "Cluny" (*Seckur*); *Die Cluniacenser* (1891–1894). An account is given in Maitland, *Dark Ages,* §§ xviii.–xxvi. The story of the English houses is briefly sketched in the second chapter of F. A. Gasquet's *Henry VIII. and the English Monasteries* (the larger ed., 1886); *see* also the same writer's *English Monastic Life.*

CLUSERET, GUSTAVE PAUL (1823–1900), delegate for war of the Paris Commune, was born in Paris, on June 13, 1823. He was an officer of the *garde mobile* during the second republic (1848), joined Garibaldi's volunteers in 1860 and in 1861 went to the United States to take part in the Civil War. After this campaign he assumed the title of General, which he said had been granted to him personally by Abraham Lincoln. He also took part in the Fenian insurrection in Ireland of 1866–67. On his return to France he became a member of the International Working Men's Association (*see* INTERNATIONAL, THE), and on the news of the Communard revolt of March 18, 1871, hurried to Paris. His military title, his advanced opinions, and his presumed talents gave him great influence among the Paris workers; he was not, however, elected a member of the Commune till the supplementary elections of April 16. After the disastrous failures of Lullier and Bergeret, the Commune appointed him to the charge of the Department of War, trusting to his record and his own assertions. But, brave though he was personally, Cluseret was hopelessly unfit to organize any military operation. He failed to introduce order into his department, to prevent the continual meddling and contradiction by the central committee of the National Guard, to organize a park of artillery, or even to relieve the men in the trenches. Under his direction, with a nominal force of 100,000

guards, the defence of Paris was maintained by no more than about 10,000, usually the same 10,000. When the Commune realized the extent of his incompetence and arrested him, on May 1, the fate of the insurrection was already decided. Cluseret had been charged with treason, but his crime was inefficiency. On May 24 the entry of the Versailles troops into Paris saved him from condemnation by the Communard courts and he escaped from France. He returned in 1884, sat as deputy for Toulon in 1888–89, and died on Aug. 21, 1900. (*See* COMMUNE.)

See *Mémoires du Général Cluseret: le deuxième siège de Paris, la fin de l'empire* (1887–88); P. Lissagaray, *History of the Commune of 1871* (1902); G. da Costa, *La Commune Vécue* (1903); R. W. Postgate, *Revolution from 1789 to 1906* (1920). (R. W. P.)

CLUSIUM (mod. Chiusi, *q.v.*), an ancient town of Italy, one of the 12 cities of Etruria, on an isolated hill at the South end of the valley of the Clanis (Chiana). It first appears in Roman history at the end of the 7th century B.C., when it joined the other Etruscan towns against Tarquinius Priscus; and at the end of the 6th century B.C. it placed itself, under its king Lars Porsena, at the head of the attempt to re-establish the Tarquins in Rome. At the time of the invasion of the Gauls in 391 B.C., the Roman envoys who had come to intercede for the people of Clusium with the Gauls took part in the battle which followed; and this determined the Gauls to march on Rome. Clusium came under Roman supremacy before 225 B.C., when the Gauls advanced thus far. The Via Cassia, constructed after 187 B.C., passed just below the town. In imperial times its grain and grapes were famous. Christianity found its way into Clusium as early as the 3rd century. In A.D. 540 it is named as a strong place to which Vitiges sent a garrison of a thousand men.

Fragments of the Etruscan town walls are built into the mediaeval fortifications. Under the town extends an elaborate system of rock-cut passages, probably drains. Extensive Etruscan cemeteries surround the city on all sides. The prevalence of cremation in the early period led to the development of the so-called *tombe a ziro*, in which the cinerary urn (often with a human head) is placed in a large clay jar (*ziro*, Lat. *dolium*). This was followed by the *tombe a camera*, in which the tomb is a chamber hewn in the rock. From one of the earliest of these came the famous François vase; another is the Tomba della Scimmia (the monkey), with a painted frieze in the central chamber. The most remarkable group of tombs is, however, that of Poggio Gaiella, 3m. to the N., where the hill is honeycombed with chambers in three storeys, partly connected by a system of passages. Other noteworthy tombs are those of the Granduca, with a single subterranean chamber carefully constructed in travertine, and containing eight cinerary urns of the same material; of Vigna Grande; of Colle Casuccini (the ancient stone door of which is still in working order), with two chambers, containing paintings representing funeral rites. Nearly 3,000 Etruscan inscriptions have come to light from Clusium and its district alone, while the part of Etruria north of it as far as the Arno has produced barely 500. Among the later tombs bilingual inscriptions are by no means rare, and both Etruscan and Latin inscriptions are often found in the same cemeteries. Many inscriptions are painted upon tiles which closed the niches containing the cinerary urns. In Roman times the territory of Clusium seems to have extended as far as Lake Trasimene. The local museum contains important objects from the necropolis, *bucchero*, sepulchral urns, painted vases, and stone *cippi* with reliefs.

Two Christian catacombs have been found near Clusium, one in the hill of S. Caterina near the railway station, the inscriptions of which seem to go back to the 3rd century; another 1m. to the E. in a hill on which a church and monastery of S. Mustiola stood, which goes back to the 4th century, among its numerous inscriptions being one with the date A.D. 303, and the tombstone of L. Petronius Dexter, bishop of Clusium, who died in A.D. 322. To the west and north-west of Chiusi-at Cetona, Sarteano, Chianciano and Montepulciano other Etruscan cemeteries have been discovered; the objects from them have mostly passed to large museums or been dispersed.

See R. Bianchi-Bandinelli in *Monumenti dei Lincei* for a detailed account of the tombs; and *cf.* D. Randall MacIver, *Villanovans and Early Etruscans* (Oxford, 1924). (T. A.)

CLUTCH, a device by means of which connected shafts or other mechanisms, such as engaging pulleys, gears and other rotating parts, may be disconnected at will. A clutch is frequently required to operate many times in the course of a minute and, as in the spindle of the automatic screw machine, which often runs at 5,000 r.p.m., it may be required to reverse its action several times within a few seconds. Clutches may be divided into two general classes, namely: Positive clutches and friction clutches.

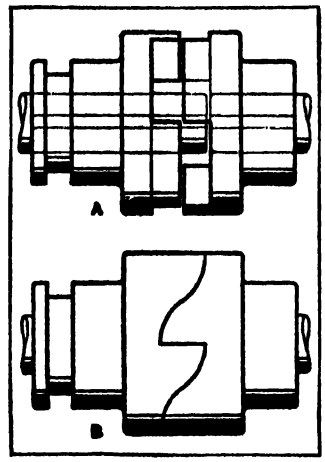

FIG. 1.—(A) CLAW OR JAW CLUTCH, (B) SPIRAL CLAW, OR RATCHET CLUTCH
The oldest form, the claw or jaw clutch, can only be put in when the mechanism is running at low speed, while with the spiral clutch, the drive cannot be reversed

Positive Clutches.—The simplest form of positive clutch is the jaw or claw type shown in fig. 1. One part of the clutch is keyed or pinned rigidly to the shaft while the other part is slotted, thus permitting it to be engaged with, or disengaged from, the first part by sliding it along the shaft. The interlocking jaws upon the abutting faces of the clutch may have various forms.

In machine tools the jaw clutch is applied extensively and is used for instantaneous disconnection of a drive to a feed screw. An automatic trip device jerks the clutch teeth out of mesh. A spiral claw clutch is utilized so that a drive cannot be reversed, this act forcing the teeth apart. Both types are shown in fig. 1.

The number of jaws on clutches depends upon the promptness with which a clutch must act. In punching and shearing machinery, the number varies from two to four, while in other classes of machinery the number of jaws may run as high as 24.

The freewheel clutch, commonly applied to bicycles, but having other mechanical applications, is another form of positive clutch. This engages the rear sprocket with the rear wheel when the pedals are rotated forwards and permits the rear wheel to revolve free from the rear sprocket when the pedals are stopped.

Friction Clutches.—The object of a friction clutch is to connect a rotating member to one that is stationary, to bring it up to speed, and to transmit the required power with a minimum amount of slippage. In connection with machine tools the friction clutch introduces what might be termed a safety device in that it will slip when the pressure on the cutting tool becomes excessive, thus preventing the breaking of gears or other parts. According to the direction in which the pressure between the contact surface is applied, friction clutches may be further divided into axial clutches and rim clutches.

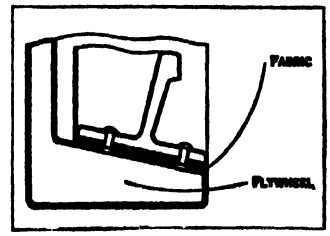

FIG. 2.—CONE CLUTCH FOR MOTOR LORRY OR MOTOR TRUCK
Used in machine tools, other apparatus and heavy automobiles. A lorry clutch is shown within the fly-wheel, with fabric lining riveted on

Axial clutches manufactured by the various builders of transmission machinery, machine tools and motor cars, are usually of one of the following three types: Cone, disc and combined conical disc. The cone clutch is the simplest form of friction clutch that can be devised, and if properly designed will give entire satisfaction in many mechanisms such as lathes, machine tools, hoisting apparatus, lorries, heavy automobiles. Two types of cone clutches, the single-cone and the double-cone, are usually met with. The single-cone clutch consists of a "male" cone of cast iron or specially treated steel keyed rigidly to a driving shaft with a second or "female" cone faced with cork, leather, asbestos, or other material, which is fitted to the driven shaft by means of a

feather key. This key permits the driven cone to be engaged with the driving cone, thus transmitting the power from one shaft to the other. The hub of the driven cone is fitted with a groove into which a shifter collar is operated by the engaging lever or toggle as shown in fig. 2. When applied to vehicles the operating lever is usually replaced by a strong spring which performs the same function. The double-cone clutch is based on similar principles.

The disc-clutch—known also as the plate clutch (fig. 3)—is a series of discs arranged in such a manner that each driven disc is located between two driving discs. The two types in common use are the single-disc in which a single disc serves as the driven member and the multiple-disc in which two or more discs act as the driven member. The single-disc clutch construction includes a fabric-faced disc which is gripped on each side between a fly-wheel or other member and a pressure disc forced up by springs, toggle levers or other devices. Multiple-disc clutches are capable of transmitting large powers at high speeds and have wide usage in motor cars, lorries (trucks), cranes, hoists and heavy gearing. A special form of hydraulically operated disc clutch is used in some American vessels, such as torpedo boat destroyers, to disconnect the cruising engines from the turbine shafts without stopping the propelling machinery.

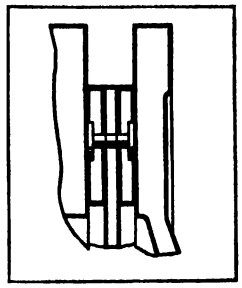

FIG. 3.—SINGLE PLATE CLUTCH, OR DISC-CLUTCH, MUCH USED IN MOTOR CARS

In addition to the asbestos-fabric faced steel disc used for the friction surfaces, the following are sometimes used: Steel against steel; steel against steel with cork inserts; steel against bronze. A combination of steel and bronze working in oil or dry steel and fabric may be used.

A combined conical-disc clutch is one in which the contact surfaces of the disc or discs are conical. In the Hele-Shaw conical disc clutch, shown in fig. 4, the driving and driven discs have a V-shaped annular groove, the sides of which form the surfaces in contact. Phosphor-bronze driving discs are provided with notches on the outer periphery which engage with suitable projections on the pressed steel casing. The mild steel driven discs have notches on the inner bore which engage with the corresponding projections on a steel spider which is splined to the shaft. The V groove in the discs permits a free circulation of oil, and at the same time ensures fairly rapid dissipation of the heat generated when the clutch is allowed to slip.

One of the recent developments with the disc type is the magnetic clutch. No toggles, lever or mechanical movements are fitted, but the friction surfaces are brought together by magnetic force when the current is switched on. As may be seen in fig. 5 the driven disc is held a little way off by a spring plate. As the coils in the driving disc are energized the resulting magnetic pull draws the driven disc against the friction lining. The magnetic pull does not attain its full value immediately and consequently the start is made without grabbing.

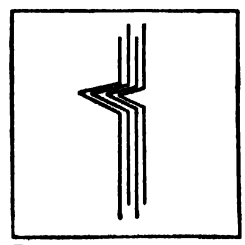

FIG. 4.—HELE-SHAW CLUTCH PLATES, WITH V-SHAPED GROOVES, THE ONLY PARTS MAKING FRICTIONAL CONTACT

In the rim-clutches pressure is obtained on the periphery of a rim and the various designs are known as block, split-ring, band, and roller, depending upon the manner in which the pressure is applied to the exterior or interior of the rim. Block clutches are used chiefly on line shafts and countershafts, although there are several designs that have given good service on machine tools. Split-ring clutches are used for all classes of service but their greatest field of application appears to be in connection with machine tools, or in places where the diameter of the clutch as well as the space taken up by the clutch is limited. Band clutches are usually installed when it is necessary to transmit heavy loads accompanied by shocks, as for example, in the drives of rolling mills and heavy mine hoist. The roller clutch is used principally for punching presses.

A block clutch used for shaft work consists of a shell running loose on the shaft, into which are fitted two brass or bronze shoes. The shoes are fastened loosely to a sleeve, which in turn is slotted to the shaft. The shoes are pressed against the inner surface of the shell by means of an eccentric screw or wedge.

The split-ring clutch consists of an outer shell running loose on a shaft or sleeve; into this shell is fitted a split-ring. The latter may be expanded by the action of a pair of levers as shown in the Heywood and Bridge clutch in fig. 6, or by means of a wedge. A sliding sleeve forms a convenient means of engaging a suitable lever. A sliding sleeve, operated by a suitable lever, forms a convenient means of engaging the split ring with the outer shell.

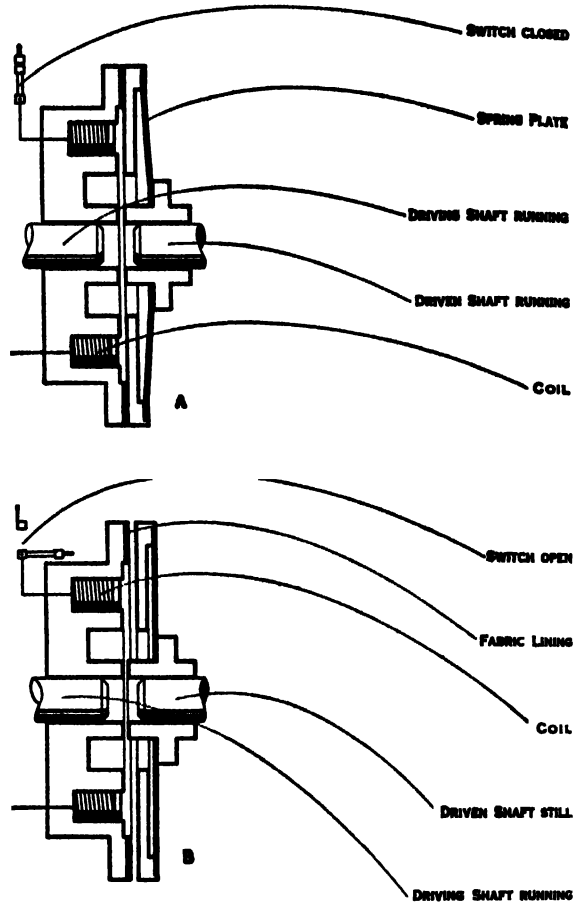

FIG. 5.—VIEWS OF MAGNETIC CLUTCH, A. SHOWING CLUTCH WITH CURRENT ON, B. WITH CURRENT OFF, IN WHICH MAGNETIC PULL BRINGS SURFACES TOGETHER WHEN THE CURRENT IS TURNED ON, TRANSMITTING OVER 2,000 HORSE-POWER IN THE LARGE CLUTCHES

In general, a band clutch consists of a flexible steel band, either plain or faced with wood or asbestos fabric, one end of which is fixed and the other is free to move in a circumferential direction. Due to the pull exerted by the operating mechanism on the free end of the band, the latter is made to grip the driving or driven member.

The roller clutch has a cam keyed to the crankshaft on the circumference of which a number of recesses, forming inclined planes, have been cut. Rollers, rolling up these inclined planes due to the action of a shell, wedge themselves between the cam and the clutch ring, thus causing the crankshaft to rotate with a flywheel. The rollers are held in place and controlled by a shell which is connected with the crankshaft by means of a spring, which is in turn operated by a treadle.

In rolling mills a special friction clutch, known as a "coil-clutch," having a flexible steel coil connected with the driven shaft and a cone on the driving shaft has been brought into use. This type of clutch has very sensitive control. On a test made in a rolling mill, a load of 11 tons was lowered by means of a crane on to an egg without crushing it and held there for three minutes.

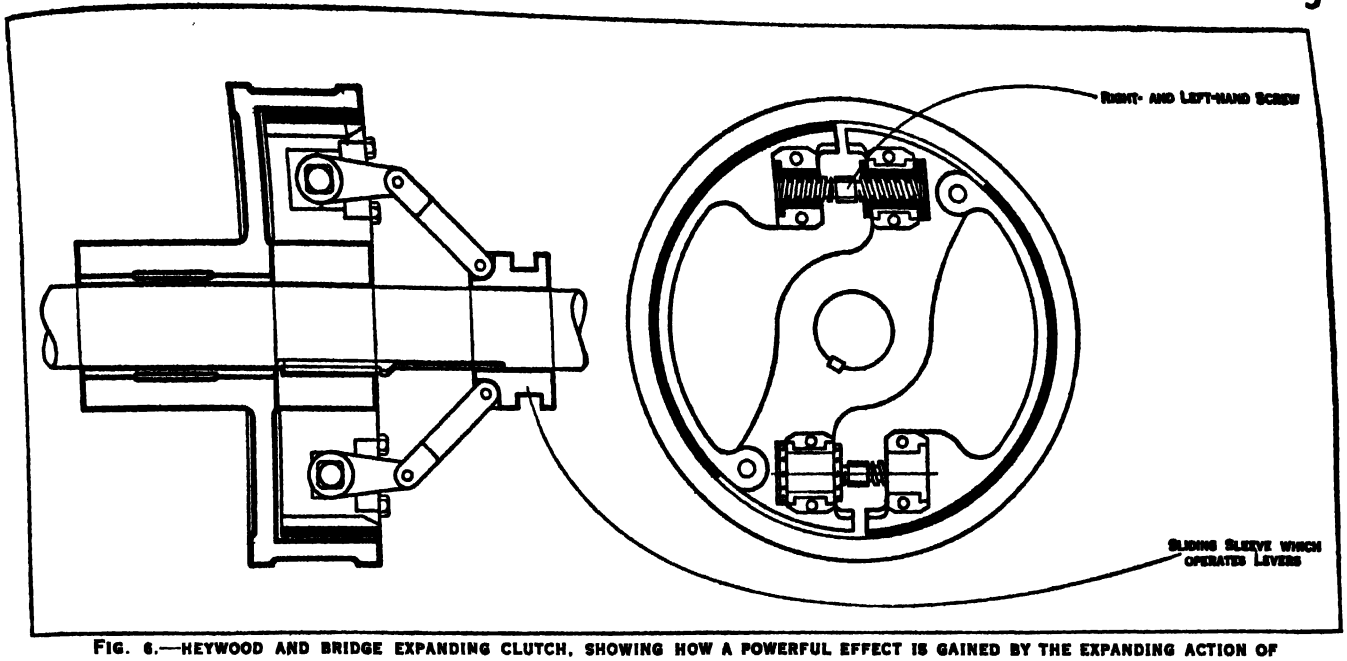

FIG. 6.—HEYWOOD AND BRIDGE EXPANDING CLUTCH, SHOWING HOW A POWERFUL EFFECT IS GAINED BY THE EXPANDING ACTION OF RIGHT AND LEFT HAND SCREWS IN DUPLICATE: AS THE SLIDING SLEEVE IS MOVED ALONG THE SHAFT, IT WORKS THE LEVERS GIVING A PARTIAL ROTATION TO THE SCREWS, AND EXPANDS THE BAND WITHIN THE SHELL. PERMISSION OF D. BRIDGE AND CO., MANCHESTER

A special application of the block clutch is the "centrifugal-clutch" which, by utilizing the principle of centrifugal force, throws out slipper-blocks against the interior wall of the clutch to enable an electric motor to obtain a proper start before picking up the load. The weight of the shoes is so regulated that when the motor is running at full speed the power transmitted by the shoes equals the power of the motor and all slip ceases.

In motor car service, it is very desirable that the car be started without jerks. In order to secure smooth clutch engagement, the designers of clutches were compelled to originate devices that insured evenness of contact between the friction surfaces. In general the function of these devices is to raise slightly the cone facing at intervals around the periphery so that upon engagement only a small portion of the friction surface comes into contact with the flywheel rim. As soon as the full spring pressure is exerted, the facing is depressed and the entire surface of the cone becomes active. In addition to securing smooth and easy clutch engagement some means must be provided to prevent the spinning of the clutch when it is disengaged. By keeping the size and

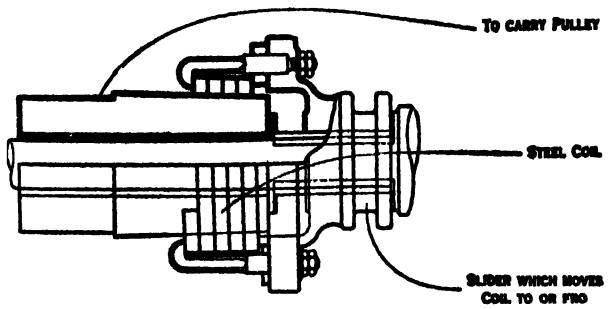

FIG. 7.—COIL CLUTCH, WHICH CAUSES GREAT FRICTION BY THE GRIP OF THE COIL WHEN IT IS THRUST ON TO A CONE ON THE DRIVING SHAFT

weight down to a minimum spinning may be reduced slightly. To overcome the spinning action completely small brakes that are brought into action when the pedal is depressed must be provided. (F. H.)

CLUWER (CLUVER, CLUVIER, CLUVERIUS), **PHILIP** (1580–1623), German geographer and historian, was born at Danzig. He studied law at Leyden, but soon turned his attention to history and geography, which were then taught there by Joseph Scaliger. He finally settled in Holland, where (after 1616) he received a regular pension from Leyden academy. In 1611 he began to publish his works. He died at Leyden in 1623. His principal writings are: *Germania Antiqua* (1616), *Siciliae Antiquae libri duo, Sardinia et Corsica Antiqua* (1619), and the posthumous *Italia Antiqua* (1624) and *Introductio in Universam Geographiam* (1629).

CLYDE, COLIN CAMPBELL, BARON (1792–1863), British soldier, was born at Glasgow on Oct. 20, 1792. He received his education at the Glasgow high school, and when only 16 years of age obtained an ensigncy in the 9th Foot. He fought under Sir Arthur Wellesley at Vimiera, took part in the retreat of Sir John Moore, and was present at the battle of Corunna. He shared in all the fighting of the Peninsular campaigns, and was severely wounded while leading a storming-party at the attack on San Sebastian. He was again wounded at the passage of the Bidassoa, and compelled to return to England. Campbell held a command in the American expedition of 1814; and after the peace of the following year he devoted himself to studying the theoretical branches of his profession. In 1823 he quelled the negro insurrection in Demerara. In 1832 he became lieutenant-colonel of the 98th Foot, and with that regiment rendered distinguished service in the Chinese War of 1842. Campbell was next employed in the Sikh War of 1848–49, under Lord Gough. At Chillianwalla, where he was wounded, and at the decisive victory of Gujarat, his skill and valour largely contributed to the success of the British arms. He was made a K.C.B. in 1849, and specially named in the thanks of parliament.

Sir Colin Campbell returned home in 1853. In the Crimean War he commanded the Highland brigade, which formed part of the duke of Cambridge's division. The brigade and its leader distinguished themselves very greatly at the Alma; and with his "thin red line" of Highlanders he repulsed the Russian attack on Balaklava. At the close of the war Sir Colin was promoted G.C.B.

The outbreak of the Indian Mutiny called for a general of tried experience; and on July 11, 1857, the command was offered to him by Lord Panmure. On being asked when he would be ready to set out, the veteran replied, "Within twenty-four hours." He left England the next evening, and reached Calcutta on Aug. 13. He started for the front on Oct. 27 and on Nov. 17 relieved Lucknow for the second time. He continued in charge of operations in Oudh until the end of the mutiny. For these services he was raised to the peerage, in 1858, as Lord Clyde; and, returning to England in the next year, he received the thanks of both Houses of Parliament and a pension of £2,000 a year. He died on Aug. 14, 1863.

See Sir Owen Tudor Burne, *Clyde and Strathnairn* ("Rulers of India" series, 1891); and L. Shadwell, *Life of Colin Campbell, Lord Clyde* (1881).

CLYDE, the principal river of Lanarkshire, Scotland (Welsh, *Clwyd,* "far heard," "strong," the *Glotta* of Tacitus), also the name of the estuary which forms the largest firth on the west coast.

The River.—Daer Water, rising in Gana hill (2,190 ft.) on the borders of Lanarkshire and Dumfriesshire, after a course of 10½ mi., and Potrail Water, rising 3 mi. farther west in the same hilly country (1,928 ft.) after running north-north-east for 7 mi., unite 3½ mi. S. of Elvanfoot to form the Clyde, of which they are the principal headstreams, though many burns in these uplands are contributory. The old rhyme that "Annan, Tweed and Clyde rise a'out o'ae hillside" is not true, for Little Clyde burn here referred to, rising in Clyde law (1,789 ft.), is only an affluent and not a parent stream. From the junction of the Daer and Potrail the river runs mainly northward, but winds eastward around Tinto hill, somewhat northwesterly to near Carstairs, where it bends west and south. From Harperfield, a point about 4 mi. above Lanark, it keeps a northwesterly direction for the rest of its course as a river. The total length from the head of the Daer to Dumbarton is 106 mi., and it drains an area estimated at 1,481 sq.mi. It is thus the third longest river in Scotland (being exceeded by the Spey and Tay), but in respect of the industries on its lower banks and its sea-borne commerce, it is one of the most important rivers in the world. Near Lanark it is broken by four celebrated falls (Bonnington, Corra, Dundaff and Stonebyres Linns) within a distance of 3¾ mi. Within this distance the river falls 230 ft. From Stonebyres Linn to the sea the fall is practically 4 ft. in every mile. The chief villages and towns on or close to the river between its source and Glasgow are Crawford, Lamington, New Lanark, Lanark, Hamilton, Bothwell, Blantyre and Uddingston. At Bowling (pop. 1,018)—the point of transhipment for the Forth and Clyde canal—the river widens, the fairway being indicated by a stone wall continued seawards as far as Dumbarton. Dunglass point, near Bowling, is the western terminus of the wall of Antoninus, or Grim's dyke.

As far down as the falls the Clyde remains a pure fishing stream, but from the point at which it becomes an industrial river its waters are contaminated. Towards the end of the 18th century the river was yet fordable at the Broomielaw in the heart of Glasgow, but since that period the stream has been converted into a waterway deep enough to allow large ships to anchor in the harbour (*see* GLASGOW). Clydesdale, as the valley of the upper Clyde is called, begins in the district watered by headstreams of the river, the course of which in effect it follows as far as Bothwell, a distance of 50 mi. It is renowned for its breed of cart horses (specifically known as Clydesdales), its orchards, fruit fields and market gardens, its coal and iron mines.

The Firth.—From Dumbarton, where the firth is commonly considered to begin, to Ailsa Craig, where it ends, the fairway measures 64 mi. Its width varies from 1 mi. at Dumbarton to 37 mi. from Girvan to the Mull of Kintyre. The depth varies from a low-tide minimum of 22 ft. in the navigable channel at Dumbarton to nearly 100 fathoms in the Sound of Bute and at other points. The Cumbraes, Bute and Arran are the principal islands in its waters. The sea lochs all lie on the Highland shore, and comprise Gare loch, Loch Long, Loch Goil, Holy loch, Loch Striven, Loch Riddon and Loch Fyne. The only rivers of any importance feeding the firth are the Ayrshire streams, of which the chief are the Garnock, Irvine, Ayr, Doon and Girvan. The tide ascends above Glasgow, where its farther rise is barred by a weir. The head ports are Glasgow, Port Glasgow, Greenock, Ardrossan, Irvine, Troon, Ayr and Campbeltown. In addition to harbour lights, beacons on rocks and lightships, there are lighthouses on Ailsa Craig, Sanda, Davaar, Pladda, Holy Isle and Little Cumbrae, and at Turnberry Point, Cloch Point and Toward Point. Health and holiday resorts on the lochs, islands and mainland coast are numerous.

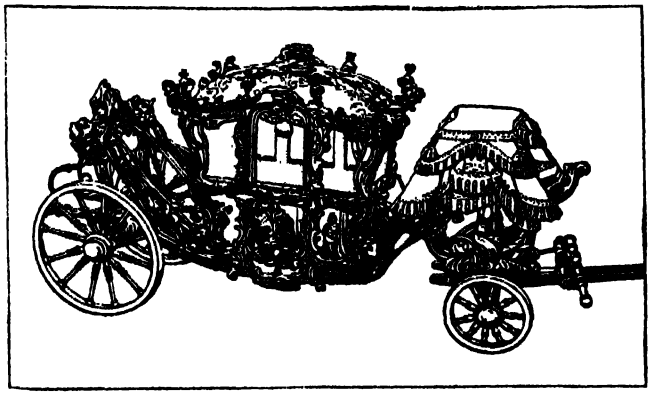
CLYDEBANK, a large burgh, Dumbartonshire, Scotland, on the right bank of the Clyde, 6 mi. from Glasgow, served by the Scottish region railway. Pop. (est. 1938) 47,912. In 1875 the district was almost purely rural, but after that date many industries were established. Dalmuir, Kilbowie and Yoker were included in the burgh in 1886, but in 1912 Yoker was incorporated with Glasgow. At Clydebank are the large shipbuilding yards and engineering works of John Brown and Co.; at Kilbowie the Singer Manufacturing Co. has a large factory, and at Dalmuir are building and repairing yards of the Clyde Navigation trust. Clydebank, with Dumbarton, returns one member to parliament. The town was nearly obliterated by German air raids in 1941.

CLYNES, JOHN ROBERT (1869–1949), English statesman, was born at Oldham, Lancs., on March 27, 1869, of working-class parents, and worked as an artisan for many years. He was active in the trade-union movement, and eventually became president of the National Union of General and Municipal Workers, and chairman of its executive council. He entered parliament as Labour member for northeast Manchester (Platting division) and sat for the same constituency from 1906 to 1931 and from 1935 to 1945. He was parliamentary secretary to the ministry of food under Lord Rhondda (1917–18), and succeeded him as minister in 1918; but resigned after the armistice.

At the beginning of the session of 1919 Clynes was elected vice-chairman of the Labour party, and chairman in 1921, but after the election of 1922 the Labour M.P.s selected J. R. MacDonald as parliamentary leader. As deputy leader Clynes moved on Jan. 17, 1924, the Labour amendment of want of confidence in Baldwin's government which brought that government down and put the labour party in office. He became lord privy seal and deputy leader of the house of commons. Clynes always spoke in the house of commons with moderation, and was always heard with respect. He was secretary of state for home affairs from 1929 to 1931. He died in London, Eng., Oct. 23, 1949.

CNIDUS, an ancient city of Caria in Asia Minor, situated at the extremity of the long peninsula that forms the southern side of the Sinus Ceramicus or Gulf of Cos. It was built partly on the mainland and partly on the Island of Triopion or Cape Krio, which anciently communicated with the continent by a causeway and bridge, and now by a narrow sandy isthmus. By means of the causeway the channel between island and mainland was formed into two harbours, of which the larger or southern, was further enclosed by two strongly-built moles. The extreme length of the city was little less than a mile, and the whole intramural area is thickly strewn with architectural remains. The walls, both insular and continental, can be traced throughout their whole circuit; and in many places, especially round the acropolis, at the north-east corner of the city, they are remarkably perfect. Knowlege of the site is largely due to the excavations executed by C. T. Newton in 1857–1858; but of recent years it has become a frequent calling station of touring steamers. The agora, the theatre, an odeum, a temple of Dionysus, a temple of the Muses, a temple of Aphrodite and a great number of minor buildings have been identified, and the general plan of the city has been very clearly made out. The most famous statue by the elder Praxiteles, the Aphrodite, was made for Cnidus. It has perished, but late copies exist, of which the most faithful is in the Vatican gallery. In a temple-enclosure C. T. Newton discovered a fine seated statue of Demeter, which now adorns the British Museum; and about 3 mi. southeast of the city he came upon the ruins of a splendid tomb, and a colossal figure of a lion carved out of one block of Pentelic marble, 10 ft. in length and 6 in height, which has been supposed to commemorate the great naval victory of Conon over the Lacedaemonians in 394 B.C.

Cnidus was a city of high antiquity and probably of Lacedaemonian colonization. Along with Halicarnassus and Cos, and the Rhodian cities of Lindus, Camirus and Ialysus it formed the Dorian Hexapolis, which held its confederate assemblies on the Triopian headland, and there celebrated games in honour of Apollo, Poseidon and the nymphs. The city was at first governed by an oligarchic senate, composed of sixty members, known as ἀμνήμονες, and presided over by a magistrate called an ἀρεστήρ but, though it is proved by inscriptions that the old names continued to a very late period, the constitution underwent a popular transformation. The situation of the city was favourable for commerce, and the Cnidians acquired considerable wealth, and were able to colonize the island of Lipari, and founded the city of

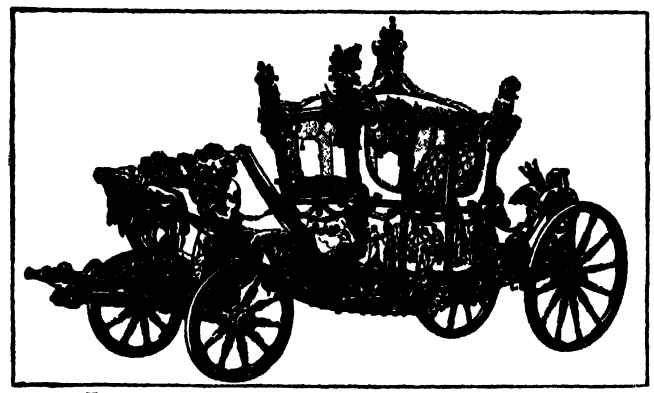


Corcyra Nigra in the Adriatic. They ultimately submitted to Cyrus, and from the battle of Eurymedon to the latter part of the Peloponnesian War they were subject to Athens. In 394 B.C. Conon fought off the port the battle which destroyed Spartan hegemony. The Romans easily obtained their allegiance, and rewarded them for help given against Antiochus by leaving them the freedom of their city. During the Byzantine period there must still have been a considerable population, for the ruins contain a large number of buildings belonging to the Byzantine style, and Christian sepulchres are common in the neighbourhood.

Eudoxus, the astronomer, Ctesias, the writer on Persian history, and Sostratus, the builder of the celebrated Pharos at Alexandria, are the most remarkable of the Cnidians mentioned in history.

See C. T. Newton and R. P. Pullen, *Hist. of Discoveries at Halicarnassus, Cnidus* etc. (1863).

COACH, a large roofed or enclosed carriage for passengers, which originated in Hungary at a place named Kocs, from which the name itself is derived through the French *coche*. As a general term, it is used (as in "coach-building") for all carriages, and also in combination with qualifying attributes for particular forms (as in stage-coach, mail-coach, motor-coach, etc.); but the typical coach implies four wheels, springs and a roof. The stage-coach, with seats outside and in, was a public conveyance which was known in England from the 16th century, and before railways the stage-coaches had regular routes (stages) all over the country; through their carrying the mails (from 1784) the term "mail-coach" arose. Similar vehicles were used in America and on the European continent. The *diligence*, though not invariably with four horses, was the Continental analogue for public conveyance, with other minor varieties such as the *Stellwagen* and *Eilwagen*.



The driving of coaches with four horses was a task in which a considerable amount of skill was required, and English literature is full of the difficulties and humours of "the road" in old days. A form of sport thus arose for enterprising members of the nobility and gentry, and after the introduction of railways made the mail-coach obsolete as a matter of necessity, the old sport of coaching for pleasure still survived, though only to a limited extent. The Four-in-Hand Club was started in England in 1856 and the Coaching Club in 1870, as the successors of the old Bensington Driving Club (1807–52), and Four-Horse Club (1808–29); and in America

STATE COACH OF THE LORD MAYOR OF LONDON, BUILT IN 1757

the New York Coaching Club was founded in 1875. But coaching remains the sport of the wealthier classes, although in various parts of England (*e.g.*, London to Brighton, and in the Lake district), in America, and in Europe, public coaches still have their regular times and routes for those who enjoy this form of travel. The earliest railway vehicles for passengers were merely the road coaches of the period adapted to run on rails, and the expression "coaching traffic" is still used in England to denote traffic carried in passenger trains.

Of coaches possessing a history the two best known in Great Britain are the king's state coach, and that of the lord mayor of London. The latter is the older, having been built, or at least first used, for the procession of Sir Charles Asgil, lord mayor elect, in Nov. 1757. The body of this vehicle is not supported by springs, but hung on leather straps; and the whole structure is very richly loaded with ornamental carving, gilding and paint-work. The different panels and the doors contain various allegorical groups of figures representing suitable subjects, and heraldic devices painted in a spirited manner. The royal state coach, which is described as "the most superb carriage ever built," was designed by Sir William Chambers, the paintings on it were executed by Cipriani, and the work was completed in 1761. During the later part of Queen Victoria's reign it was hardly ever seen,

THE BRITISH ROYAL STATE COACH, COMPLETED IN 1761

This coach is used only for ceremonial occasions such as the opening of parliament. The panels and door are covered with emblematic devices

but on the accession of Edward VII. the coach was once more put in order for use on state occasions. The following is an official description of this famous coach:

"The whole of the carriage and body is richly ornamented with laurel and carved work, beautifully gilt. The length, 24 ft.; width, 8 ft. 3 in.; height, 12 ft.; length of pole, 12 ft. 4 in.; weight, 4 tons. The carriage and body of the coach is composed as follows:—Of four large tritons, who support the body by four braces, covered with red morocco leather, and ornamented with gilt buckles, the two figures placed in front of the carriage bear the driver, and are represented in the action of drawing by cables extending round their shoulders, and the cranes and sounding shells to announce the approach of the monarch of the ocean; and those at the back carry the imperial fasces, topped with tridents. The driver's foot-board is a large scallop shell, ornamented with bunches of reeds and other marine plants. The pole represents a bundle of lances; the splinter bar is composed of a rich moulding, issuing from beneath a voluted shell, and each end terminating in the head of a dolphin; and the wheels are imitated from those of the ancient triumphal chariot. The body of the coach is composed of eight palm-trees, which, branching out at the top, sustain the roof; and four angular trees are loaded with trophies allusive to the victories obtained by Great Britain during the late glorious war, supported by four lions' heads. On the centre of the roof stand three boys, representing the genii of England, Scotland and Ireland, supporting the imperial crown of Great Britain, and holding in their hands the sceptre, sword of state, and ensigns of knighthood; their bodies are adorned with festoons of laurel, which fall from thence towards the four corners. The panels and doors are painted with appropriate emblematical devices, and the linings are of scarlet velvet richly embossed with national emblems."

We may observe how the difficult art of driving a coach was responsible for the use of the terms "coach" and "coaching" to mean tutor or training for examinations or athletics.

See the Badminton *Driving*, by the duke of Beaufort (1888); Roger's *Manual of Driving* (Philadelphia, 1900); and "Nimrod's" *Essays on the Road* (1876).

COACHING. The 20th century witnessed in its first quarter the passing of a style of conveyance which was at one time universal, and has inspired the artist, the poet and the author to work that will remain long after the last coach has ceased to be seen on the roads. To say that four-in-hand driving will die out entirely is to take an extreme view, but while railways and motor cars hold their own there will be little chance for the art on our country roads—at any rate in comfort.

The reader need hardly be told that in early days the roads were so bad in Great Britain that wheeled traffic literally made slow progress, and nearly everybody rode; but towards the end of the Commonwealth period social life had demanded a better means of communication from place to place. Accordingly the stage coach made its general appearance, and in spite of a good

deal of opposition, and the usual charge of effeminacy, remained. As might be expected the pace for many years was not great, and at first the coaches travelled only by day, the "flying coaches," as they were called, covering between forty and fifty miles in the day of 12 hours—in fine weather.

It must be remembered that coaching even in its palmiest days had its detractors, for the weather had to be taken into consideration, while the roads themselves till the days of Telford and Macadam left much to be desired, and accidents were much more numerous than is the case to-day with railways. Still its utility was beyond argument, but the question of speed arose, and it should also be borne in mind that the slowness of the pace rendered the stage coach an easy prey to the highwaymen, who then abounded. The post office at the time favoured the plan of mounted "expresses," and the slowness of the postal service was especially noticeable on the Great North Road, it being said that "every common traveller passes the King's Mail on the first road in the kingdom." Indeed at that time the stage coach itself was a speedier conveyance than the ordinary postal system.

The moment brought the man, and it was John Palmer, the proprietor of the theatre at Bath, who in 1784 put the first mail coach on the road, running from Bristol to London at the rate of about seven miles an hour. The mail coach speedily found favour, and, as its name implies, it may be termed the special *protégé* of the post office; of course it did not exterminate the stage coach, the two existing side by side till the advent of railways drove them both off the road together.

The driving of four horses appealed to the sporting gentlemen of the day, who drove their own vehicles, or who would take a stage or two on the regular coaches, with the connivance of the professional driver. Some well-known amateur coaching clubs were formed, including the Four Horse and the Bensington driving clubs, both of which in due course passed away. It was in 1856 that the Four-in-Hand driving club was formed and lasted down to 1927, while in 1870, owing to the Four-in-Hand driving club only receiving a limited number of members, the still existing coaching club was established. Though its members do not turn out in as great numbers as they did, it still keeps the spirit of the pastime alive at the meets at the Magazine in Hyde Park. Here, however, the pleasure of driving four horses is the only consideration and no "passengers" are taken for remuneration.

Later on a number of what may be termed subscription coaches were placed upon the road, which usually ran to various places within a radius of something like 50 miles of London, and till the appearance of the motor car they were very popular. They have, however, practically disappeared, with the death of the last of the London enthusiasts who was able to indulge his hobby, though two roads were kept open in 1927.

In the past many private gentlemen, especially masters of hounds, would indulge in driving tours through various parts of the country, and in 1926 one well known master in the North afforded his friends and subscribers a very pleasant afternoon's outing. At the holding of some of the great horse shows, notably Richmond and Olympia, coaching classes are popular and often well patronized, for it must be remembered that the regimental coaches, that is coaches kept up by various regiments in the service, have not yet gone out of fashion. Indeed it will probably be very many years before the art of driving four horses is lost entirely in Great Britain. (*See* DRIVING.)

COAHUILA, a northern frontier state of Mexico, bounded north and northeast by Texas, east by Nuevo León, south by San Luis Potosí and Zacatecas, and west by Durango and Chihuahua. Area, 58,052 sq.mi. The population in 1950 was 720,145. Its surface is a roughly broken plateau, traversed by several ranges of mountains and sloping gently toward the Rio Grande. In the western part there are extensive areas of level land, many of them enclosed drainage basins, the largest of which is the Bolsón de Mapimí, a great depression which was long considered barren and uninhabitable. Experiments with irrigation, however, were highly successful and considerable tracts were later brought under cultivation. In general the state is insufficiently watered, the rainfall being light and the rivers small. The rivers flow eastward to the Rio Grande. The climate is hot and dry, and generally healthful. Stock raising was for a time the principal industry, but agriculture has been developed in several localities, among the chief products of which are cotton—Coahuila is the principal cotton-producing state in Mexico—Indian corn, wheat, beans, sugar and grapes. The Parras district in the southern part of the state has long been celebrated for its wines and brandies. The mineral products include silver, lead, coal, copper and iron. The mining operations are chiefly centred in the Sierra Mojada, Sierra Carmen and in the Santa Rosa valley. The modern industrial development of the state is due to the railway lines constructed across it during the last quarter of the 19th century, and to the investment of foreign capital in local enterprises. The first Spanish settlement in the region now called Coahuila was at Saltillo in 1586, when it formed part of the province of Nueva Viscaya. The capital of the state is Saltillo. Among the more important towns are Parras, pop. (1940) 15,555, 98 mi. northwest of Saltillo, one of the largest railway centres in the country, and Piedras Negras (formerly Ciudad Porfirio Díaz) on the Rio Grande.

COAL AND COAL MINING. To modern civilization there has been no other substance in nature except air, soil and water so important as coal. This black, earthy matter is a small potential dynamo—a so-called mineral derived from the dense vegetation of hundreds of millions of years ago. Within each piece is a vast store of energy drawn from the sun. The better the grade of coal, the more carbon it contains; when coal is burned by combining it with oxygen in the air, the intense heat hoarded up from the rays of the sun of the so-called Carboniferous period is released. It is the working power of coal that makes it so important to mankind. One pound of it, burning in a modern engine, can produce as much work as a workman doing hand labour could in an entire day.

In the pages which follow, coal and coal mining will be considered in these separate sections:

I. Origin and Kinds of Coal; First Uses
II. Types and Methods of Coal Mining
III. Surface or Strip Mining
IV. Coal Mining in Great Britain
V. Coal Mining in the United States
VI. Hazards of Mining and Measures of Safety
VII. Chemical By-Products of Coal
VIII. World Coal Resources and Production

I. ORIGIN AND KINDS OF COAL; FIRST USES

Coal is of organic origin, formed from the remains of living things such as trees, herbs, shrubs, vines and other plant materials that flourished millions of years ago, during periods of widespread uniformly mild, moist climate. From this variety of vegetation and its complex carbon compounds came a great assortment of coals, from brown coal and lignite or peat to the hardest kind of anthracite.

Coal consists chiefly of carbon, derived directly from organic carbon compounds such as starch, sugar and cellulose which with water form the bulk and substance of vegetation. The carbon in the plants that later formed coal was not obtained from the soil by way of plant roots, but from the air by way of leaves. Being the only known natural agency known capable of abstracting large amounts of carbon from the air, plants employ it in the construction of their own tissues and store it up for future use. The mechanism by which this is accomplished is the plant cell with its green colouring matter. The energy utilized by plants in building up the organic substances out of carbon dioxide and water is that portion of the sunlight absorbed by the green material.

Geology and Types of Coal.—Coal is fossilized plant material, preserved by burial and altered by earth forces. Although it is usually bedded, isolated pieces exist. The character of a coal depends upon the nature of the original plant debris, the extent and character of its decay and weathering before burial (diagenesis), and upon the geological vicissitudes subsequently undergone.

Selective diagenetic processes tend to concentrate the more resistant components of the peat. Differences in coal arising from initial differences in composition or from the selective effects of diagenesis constitute type differences; differences arising from variability in earth forces constitute rank differences. Common banded coal, cannel coal and splint coal are three common type varieties; lignite, subbituminous coal, bituminous coal and anthracite are four common rank varieties. Each type of coal is, theoretically at least, represented in each rank.

Geological forces mainly result in compaction and condensation; the former, a physical process, results in loss of pore space, moisture and oxygen; the latter, a chemical change, results in an increase in residual carbon. These changes increase the density and heat value of the coal. Coal rank classification, therefore, has been based upon moisture content, oxygen content and heat value singly or in various combinations. Relative density, blackness and reflectivity also provide rough indices of rank.

The coking capacity of coal is produced by geological forces concurrently with compaction and condensation. In general, it is restricted to bituminous coal and reaches its best expression in medium and low volatile coals. Coking quality is, therefore, also a criterion for rank classification.

Depth of burial is an important factor in determining the rank of a coal. However, the higher-rank coals have been subjected to other earth forces than simple hydrostatic pressure, for such coals are found where rocks have been folded or otherwise modified by earth forces, such as by contact with igneous rocks. Low-rank coals on the other hand are characteristic of plains regions where the weight of overlying sediments has been the main source of alteration.

The coalification process terminates in the transformation of coal into incombustible mineral carbon or graphite. Graphitic coal is found only in association with severely altered rocks.

The age of a coal is no criterion of its rank. Immature coals may be of great age (Carboniferous lignitic coal of the Moscow basin), and anthracitic coal may be of relatively recent age (Eocene anthracite of Thrace and Switzerland).

Coal is known in all geological systems since the Silurian. Graphitic rocks suggest that coal formation may date back to pre-Cambrian time. The Devonian coal represents very primitive land plants; Tertiary coals, on the other hand, represent debris from relatively modern trees. Hence there is apparently no limit to the kind of land plant that may be the source of coal. Coal beds are most important in the Carboniferous system of the Palaeozoic rocks, Lower and Upper Cretaceous systems of the Mesozoic and throughout the Tertiary systems. The greatest quantity of coal material is probably in the Tertiary rocks, but the greatest quantity of high grade coal is in the Carboniferous system.

Most bituminous coals appear banded in hand specimens, and the banded ingredients, vitrain, clarain, durain and fusain, have been differentiated as vitreous and black, bright and striated, dull or charcoal-like respectively. In thin sections the woody material (mainly vitrain), which often can be clearly identified has been called anthraxylon by R. Thiessen, the charcoal-like material fusain, and the heterogeneous matrix attritus. Attritus that appears predominantly opaque is the equivalent of durain of hand specimens and of splint coal. Type variations in coal result from variations in the proportion of the banded ingredients or of the botanical components observed in thin sections, since both result from variations in the character of initial material when buried.

The following definitions augment the brief explanations of certain varieties of coal mentioned above:

Lignite is a low-rank brown to black coal, in which the original plant components are discernible. It gives a brown streak and disintegrates rapidly upon exposure. It burns with little or no smoke, and is largely soluble in alkalies.

Subbituminous coal is a low-rank banded, black coal with woody layers commonly visible. It disintegrates in the air, but fairly slowly. It has a brown streak and smokes when it burns. It is noncoking and insoluble in alkalies.

Bituminous coal is a medium- to high-rank black, usually banded, coal, with coking qualities poorly developed in high volatile coals but well developed in medium to low volatile coals. It weathers slightly or not at all. It is insoluble in alkalies and gives a black streak when fresh. It smokes when it burns. Three common type varieties are *normal banded* coal, *cannel* coal, which is an unbanded coal with silky lustre, grossly conchoidal fracture and with a large proportion of waxy components mainly in the form of spore exines, and *splint* coal, a dull, faintly striated coal, opaque in thin sections and with a somewhat metallic ring when sharply struck. Neither cannel nor splint coal usually possesses coking properties.

TABLE I.—*Classification of Coals*
(Computed on ash-free basis)

Rank	Moisture (per cent)	Volatile matter (per cent)	Fixed carbon (per cent)	Heat value (B.T.U.)
Lignite	43.4	18.8	37.8	7,400
Subbituminous	23.4	34.2	42.4	9,720
Low-rank bituminous	11.6	41.4	47.0	12,880
Medium-rank bituminous	5.0	40.8	54.2	13,880
High rank bituminous	3.2	32.2	64.6	15,160
Low-rank semibituminous	3.0	22.0	75.0	15,480
High-rank semibituminous	5.0	11.6	83.4	15,360
Semianthracite	6.0	10.2	83.8	14,880
Anthracite	3.2	1.2	95.6	14,440

From M. R. Campbell, "*The Coal Fields of the United States*" (U.S. Geological Survey, Paper 100-a).

Anthracite is a high-rank coal of dense rocklike texture, a glassy lustre and conchoidal fracture. Although faintly banded, banding does not determine breakage. It has a black streak. It does not coke and burns with a nonluminous flame. (G. H. CA.)

Early Uses.—There is general archaeological evidence that during the Bronze Age, 3,000 to 4,000 yr. ago, the people living in what is now Glamorganshire, Wales, used coal for funeral pyres. Remains of coal fires have been found in Roman forts and dwellings on Hadrian's Wall, dating from A.D. 121. Coal served as a fuel in China some time before the Christian era. We find various references to coal in the Bible, and among Greek and Roman writers before the birth of Christ. The Anglo-Saxon Chronicle records for the year 852 that "60 loads of wood, 12 loads of coal, 6 loads of peat, etc." were to be paid in rent for Sempringham, the land let to Wulfred, by the Abbot Ceobred, having to do with the Abbey of Peterborough.

After the invasion of the Normans in 1066, though, coal apparently was not important enough to be mentioned in the Domesday Book, there is evidence that monks of the 11th century often used it in their forges to produce the ironwork for which they were famous. It was certainly in fairly common use in the early middle ages. Travelling pilgrims brought news of the new fuel to the south of England from Northumberland and Durham, where coal could be picked up on the seashore. As early as the 13th century coal was brought down the east coast of England to London in small coastal barges. It was burned so inefficiently in those early days, giving off smoke and what were considered poisonous odours, that a great deal of prejudice developed against its use. At one time King Edward I (1239–1307) imposed the death penalty upon any person caught using coal for fuel purposes. This prejudice continued for some time thereafter, even through the reign of Elizabeth. One reason why it could not be used easily in houses was that chimneys were made of iron and were therefore very expensive. Toward the end of the 15th century, however, a new material appeared—bricks, made easily and cheaply in coal furnaces. Bricks made it possible for everybody to have chimneys and to burn coal in their hearths. It took some time, of course, to perfect even brick chimneys to draw properly, so that heavy smoke and fumes did not escape into dwellings. In the houses of the well-to-do, however, coal became more and more popular. Thomas Cardinal Wolsey's Hampton Court palace is an example of the ornamented brick chimney shafts which became fashionable in Tudor times.

In 1735, when Abraham Darby patented his blast furnace, coal began to be used in the production of iron. What had hitherto been a rare and expensive metal became now something of common use throughout England and eventually in North America.

Coal was first discovered in the United States by Louis Joliet and Jacques Marquette in 1673. A map published with Mar-

quette's *Journal* of 1681 shows that coal was found near the present city of Utica, Ill. Father Louis Hennepin, accompanying La Salle's expedition to the Illinois country in 1680 as chaplain, in his book *A New Discovery of a Vast Country in America* published in England in 1689, referred to the fact that coal had been found near the Illinois river.

It was not until 1745, however, that a coal mine was actually operated, near Richmond, Va.; some coal was sold commercially in that year. Coal was discovered in Ohio in 1755. All of these deposits were of the bituminous variety. Anthracite was first mined in Pennsylvania about 1790.

George Washington, writing in 1770 in his *Journal of a Tour of the Ohio River,* made a notation of a coal mine near the river bank where "coal seemed to be of the very best kind, burning freely and an abundance of it." In the sparsely populated colonies, however, native coal was not widely used. Up to the time of the Revolutionary War, most of it came from England or from Nova Scotia for limited industrial uses in towns along the Atlantic coast. With supplies curtailed during the long war, some use of the native coal was made by the blacksmiths for manufacturing munitions for the Continental army. After the Revolution the infant industry expanded, mostly in areas adjacent to the mines. It was also something of a problem to convince a skeptical public of the value of the newfangled fuel. Word had come from France in a roundabout way that a law had been passed there forbidding any workman from burning coal in Paris, under heavy penalty, because it was believed that coal fumes caused serious epidemics of disease.

Nevertheless, coal came to be used more and more in the United States. As bituminous coal was found close to the surface of the earth and required little expense to dig, farmers in their spare time peddled it to neighbouring blacksmiths and to a few persons who used it for heating their homes. Early farmers frequently would not allow a seam very far underground to be dug up because of a superstitious fear. But they often leased their mineral rights to others. As small companies were organized to mine the coal, the farmers and their farm hands frequently worked for the new owners in the winter months.

In the early 1830s numerous small mining companies sprang up, notably in the Appalachian regions and along the Ohio, Illinois and Mississippi rivers. As a rule they had little capital and few survived. It was not until the 1840s that the U.S. coal industry mined its first 1,000,000 tons, and from then on the growth was steady and accumulative. The industry received a tremendous impetus from an entirely unexpected source with the advent of the railroad. The problem of transportation was solved and an immense new national market had been opened.

In England, as mines grew deeper, the winding or lifting of coal to the surface of the earth from mine bottoms became more difficult. In early times the coal was carried up ladders by the miners themselves; later it was wound up in baskets by "whim gins" worked by horses. Then came James Watt's rotary engine, which was first used for winding coal at the deep Walker colliery in 1784.

Water had been another problem in the English mines from the earliest times and had limited the depths to which mines could be sunk. Then came Thomas Newcomen with his first steam pump built at Wolverhampton in 1711—the pump which contained the germ of the idea for the first steam engine. Thus an efficient pump for draining water inside the mines appeared.

A third difficulty in the British mines was that of hauling coal from the face or working area of the mine to the pit bottom. This had to be done by hand or by back-breaking human labour, or by animal power. George Stephenson's steam pump (1812), however, enabled tubs of coal to be pulled to the bottom of the pit shaft. Thus, Newcomen, Watt and Stephenson helped revolutionize early coal mining.

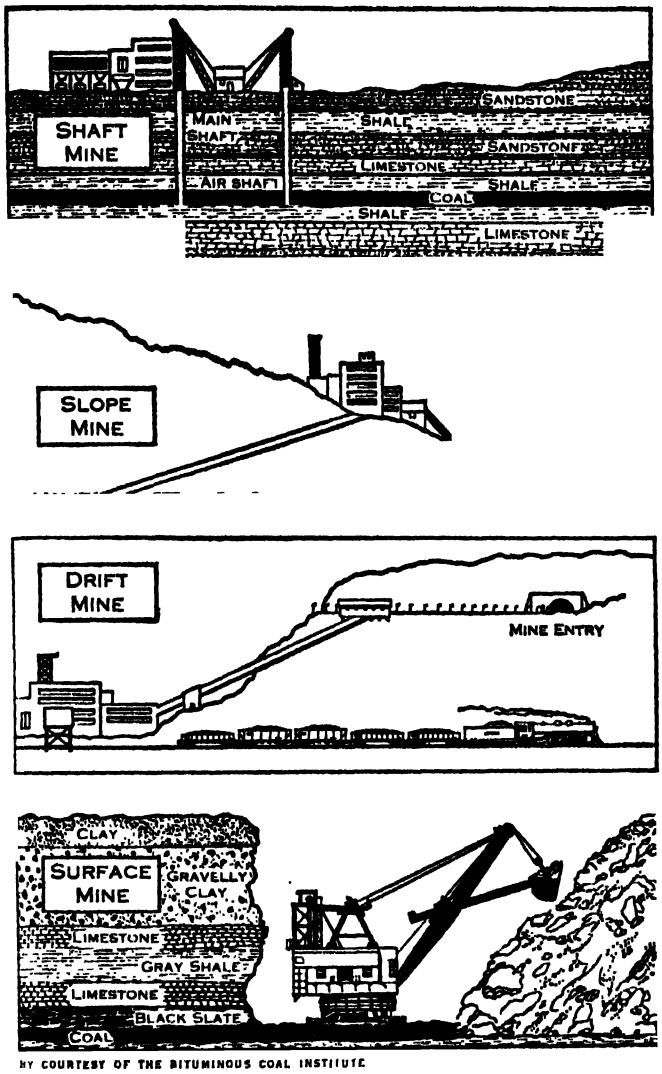
II. TYPES AND METHODS OF COAL MINING

There are two general methods of mining coal: underground or deep mining; and surface or opencut (sometimes called strip) mining. The latter method is used when the coal bed lies near the surface of the earth, where the thickness of the so-called overburden of the earth and rock atop the coal permits it to be stripped away by giant power shovels, and the coal seam or coal bed is wide or deep enough to justify tearing up the surface of the land covering the coal. More often than not such land is submarginal, of no great agricultural value, and the coal deposits are of much greater economic value. Of the strip or surface mines, more will be said later in this article.

Underground mining is of three types, depending on the nature of the terrain, the thickness of the coal seam or vein and on whether the coal is embedded in a hilly or a mountainous country or in flat areas. These are shaft mines, drift mines and slope mines. The following is a general description of the various types of underground mines and the methods of extracting coal from the earth.

In the shaft mine, at least two vertical shafts are sunk into the earth. One brings the coal to the surface and transports the miners, by means of "cage," "skip" or elevator (U.S.), or "lift" (England), from the top entrance to the working floor of the mine and from one level of the vertical shaft to the other. The second shaft is used to draw fresh air into the working area below by a fan located at the top of this shaft; and to expel the foul air drawn up from below. Depths of shaft mines vary greatly in different parts of the world, depending upon the richness of the deposits and the extent of underground workings. The average depth of shaft mines in the United States is about 190 ft., and the deepest mine known in the states at mid-20th century was that of the Gallup Gamerco company in McKinley county, N.M.—839 feet. Average depth of shaft mines in Great Britain is 1,167 ft., and the deepest mine known there at mid-century was 4,200 ft.

In a slope mine, the opening is made by a bore that goes down to the coal seams on a gradual incline. These mines are not as deep as the shaft mines but the underground workings extend horizontally for great distances, sometimes for many miles.



The outcrop in a drift mine is reached either by a tunnel or a horizontal bore into the side of the hill.

Whereas in shaft mines the worker is taken down in "skips," he reaches the working area of a drift mine by being carried in trains of mine cars—designated in the U.S. "man-trips"—pulled by especially designed electric locomotives. If the grade is a gentle one in a slope mine, the miners are transported in the same way as in the drift mine. In some slope mines trips are moved by a cable operated by a hoist or windlass which pulls them to the surface and keeps them from going downgrade too fast. The difference between transportation in a drift mine as compared with a slope mine is that between the use of a more or less level tunnel driven into the coal seam from the side of the hill, using, as in the case of the slope mine, an inclined entry driven from the surface down to the coal seam.

The thickness of coal seams underground varies greatly. China is said to have the world's largest coal bed—400 ft. in thickness. Two seams in Wyoming are 90 ft. or more in thickness. Other seams in North America are 40 and 50 ft. thick but the average thickness in bituminous mines is 5.4 ft. The bulk of bituminous coal in the United States, by far the most prevalent, is taken from seams varying from 3 to 10 ft. in thickness. A few U.S. coal seams, only 18 in. in thickness, have bituminous value in them sufficiently great to justify underground mining. Anthracite beds in Pennsylvania vary in thickness as mined from approximately 3 ft. or slightly less to the Mammoth mine in the southern Pennsylvania field, with a thickness of 29 ft. 1 in. The majority of the anthracite coal beds are 4, 5 and 6 ft.; the deepest is 1,300 ft. Generally speaking, anthracite seams are deeper, thinner and more frequently broken than those of bituminous. In Great Britain thickness of seams runs from 2.9 ft. to 5.4 ft., the general average being approximately 4 ft.

Methods of Underground Mining.—In the United States almost nine-tenths of the coal is removed from underground mines by the *room-and-pillar method.* About 50% or more of the coal is recovered by this method in the first working. The rooms are dug out adjacent to the main gallery or entry. The coal is mined in these rooms which are separated by narrow ribs or pillars.

Wooden props or pillars are left to support the roof. The rooms are dug systematically like the blocks and alleys of a city, and the tunnels extending to the rooms lead along the seam of coal. The coal in the pillars is won by subsequent working, which may be likened to top slicing, in which the roof is caved in successive blocks.

BY COURTESY OF THE BITUMINOUS COAL INSTITUTE

FIG. 1.—TYPES OF COAL MINES

The first working in rooms is an advancing and the winning of the rib, or pillar, by a retreating method. Rooms are driven parallel with one another and the room faces may be extended parallel, at right angles or at an angle to the dip. Once the pillars of coal have been removed the roof is allowed to fall in. The removal of these pillars is important because some of them may be 50 to 80 ft. in thickness and if they were not removed about one-third of the coal would be lost. These masses of coal, some of them as long as the rooms which they help to hold up while the miners are working inside, are taken away systematically; *i.e.*, the pillars farthest from the mine opening are removed first and those nearest the portal last.

In the second underground means of removing coal—the *long-wall* or *pillar-and-breast* technique, the working places are rectangular rooms usually five or ten times as long as they are broad, opened on the upper side of the gangway. The breasts, usually from 5 to 12 yd. wide, vary with the character of the roof. The rooms or breasts are separated by pillars of solid coal, broken by small cross headings driven for ventilation, from 5 to 10 or 12 yd wide. The pillar is actually a solid wall of coal separating the working places. When the object is to obtain all the coal that can be recovered as quickly as possible the pillars are left thin. Where this plan is likely to cause a crush or squeeze that may seriously injure the mine larger pillars are left.

After the mine has been worked out, the pillars are removed by mining from them, until the roof comes down and prevents further working.

In the mines of Great Britain this method of extracting coal underground is called the *bord-and-pillar* system and there are modifications of the system both in England and America, in the pillar-and-stall, post-and-stall, single and double stall, wide or square work, rearer workings, etc. In the longwall system, popular in England, the whole seam is taken out and no pillars left except the shaft pillars and sometimes the main-road pillars. This system, too, has its variations.

Mechanization.—By mid-20th century, the United States had achieved by all odds the greatest amount of mechanization in the mining of coal. Ninety-one per cent of all bituminous coal mined underground was cut mechanically, and 64% of the loading was done mechanically, with the percentage constantly increasing. Cleaning and sizing were mechanized. Electric machines to undercut coal often took slices seven inches thick and six to nine feet back under the bottom of the seam, thus permitting the coal to break up more easily when the explosive was discharged. Mechanical loading machines, some able to load a five-ton car in less than one minute, performed the work which used to take a miner several hours of hand labour to do. Small electric locomotives hauled the loaded coal cars, in trains of 50 or more cars, to the bottom of the shaft. In some mines, conveyor belts did the entire job of moving the coal from the working face all the way to the mine exterior. Some of these belts, carrying the coal from one huge unit to another, could transport coal as many as 15 mi. inside a large mine before delivering it outside to the tipple. These conveyor belts took the place of the underground train of cars.

Wooden man-trip cars, employed to take miners to their working places in slope or drift mines, from the side of the hill or mountain, were being replaced by all-steel cars, electrically operated, carefully roofed and carrying 38 men each. Some of these cars travelled five miles or more underground, each way, from the portal entrance to the face, in reaching the working area. U.S. mines had more than 250,000 mi. of underground track for these cars.

One of the first tasks in taking coal from the face is that of boring blast holes in the solid coal. A mobile electric drill does this work. The miner does not hold the drill; it is suspended from a boom, somewhat like a dentist's drill, and the workman swings it easily to the place where it is needed. Nor does he have to carry the drill anywhere. Both drill and boom are mounted on an electric mine locomotive which can travel everywhere in the mine. It can cut holes at any elevation for the eventual placing of the shots that will break down the coal and its wide swing allows it to be operated easily either horizontally or vertically.

Cutting machines, like the electric drills, may be rubber-mounted or run on tracks. The use of this huge electric mechanism for making advance cutting allows for expansion when the coal is later blasted loose from the seam. This coal cutter has an endless chain with projecting bits which chew out a deep channel in the coal face. First a horizontal cut is made, then a vertical slot will be cut near the centre, after which, the face is ready to be shot fired.

Before any blasting is done, the electric drill puts a series of holes into the coal preparatory to tamping permissible explosives into the holes. To prevent the danger of sparks, a wooden tamper is used to shove the explosive home. Afterward, the firing will crumble the coal into large pieces which are removed later by a loading machine. The modern coal mine shovel, a crocodilelike contraption with headlamps for eyes, is one type of mechanical loader used in U.S. mines. Its teeth, revolving toward the centre of its mouth, pick up the loose coal and pile it onto a conveyor belt which carries the coal back over the head of the machine and into a waiting coal car. A single machine like this is capable of loading up to six tons of coal each minute.

Instead of using explosives, many U.S. mines do the shooting by the sudden release of compressed air. In the Airdox system a

miner inserts a cylinder into the hole made by the drilling machine, into which air at 10,000 lb. per square inch pressure is compressed. Once the compressed air is released within the face, its gentle breaking effect on the coal assures a larger range of grades or sizes and at the same time provides a safety factor in the blasting process.

With two-thirds of U.S. underground loading done by machinery at mid-20th century, the hand loading of coal was rapidly going out of fashion. A tire-mounted engine transfers the broken coal rapidly to a rear conveyor. It then loads the coal swiftly into the mine car which is then pulled away by a locomotive or another "shuttle-buggy," and an empty car automatically takes its place. Or the broken coal may be dumped onto conveyor belts which move the coal directly to the cleansing plant.

The continuous mining machine, first demonstrated in 1948, replaced the cyclical, step-by-step mining sequence and combined in one continuous operation all of the other steps, using a minimum of manpower. One type produced two tons per minute, although the actual speed varied according to the characteristics of each seam and from mine to mine. It eliminated altogether the drilling and shooting operations, but posed the problem of conveying the coal away fast enough in bulk to the surface or the cleansing plant.

The "coal mole" (trademark "Colmol" of the Jeffrey Manufacturing company) continuously gouges out coal from the solid face without use of the four ordinary mining machines for undercutting, drilling, loading or hand-shovelling. The Colmol, boring forward like a mole in the ground, is powered electrohydraulically and is mounted on caterpillar tractor treads that can be made to meet various heights of the coal seams. On its head are ten revolving cutters, each cutter having four bits. It operates with light fingertip control, and moves steadily and continuously ahead in the solid coal without vibration, often producing a four-ton flow of coal per minute in a four-foot high seam.

Some idea of the extent of mechanization in U.S. coal mining may be gathered from transportation trends in underground work. At mid-century the total track haulage was estimated at 30,000 mi., and approximately 500,000 mine cars and 16,000 locomotives ran on those underground tracks. The average mine had 33 cars for each locomotive. About 750,000 mine cars were in use for underground work. The majority of the locomotives were electric-powered, and the average length of each belt conveyor was about 850 ft. The advantage of a long belt installation lies in the fact that it gives a transportation medium that has natural space conformations to mining, and approaches the goal of a continuous flow of coal from face to tipple or breaker, with a minimum of operating costs. From 40% to 50% of the locomotives used at mid-century were 10 tons or more in size, the trend being toward increasingly larger units. Some manufacturers were making locomotives only in sizes of 15 tons or more, and few storage battery locomotives were used. Many mine companies preferred tandem locomotives for heavy-duty work, the largest of these consisting of two 25-ton locomotives connected in permanent tandem, and equipped with six 120-h.p. motors. Hydraulic and pneumatic braking systems were employed.

III. SURFACE OR STRIP MINING

When coal was first discovered, it lay on the surface of the earth in exposed ledges or outcroppings. In time this fuel was exhausted and man scratched back the earth and followed the coal seams underground. That was the way opencut or surface mining began—so-called because the open cuts or trenches laid the coal seams bare, making it possible for more coal to be removed. It became more and more difficult, however, to remove the masses of overlying dirt, rock and shale, even with horse-drawn or other animal-drawn scrapers, to say nothing of small shovels in the hands of workmen. Coal mining thereafter had to be carried on underground, in tunnels driven into the hillsides, or eventually by huge bores tunnelled straight down into the earth within which miners could be hauled down and up again. It did not take long for early underground miners to learn the dangers of mining coal that lay too close to the surface. Unless there was a solid rock roof above them which could be propped up while they were digging the coal, the tops of these tunnels would cave in. Thus shafts were dug; still deeper veins were reached and great buried coal resources were revealed. But there were still left millions of tons of surface coal—too close to the earth's exterior to mine safely from underground and yet too deeply embedded to be reached with the simple tools and slight equipment available to miners. Thus opencut or surface mining, called opencast mining in Great Britain, developed. By mid-20th century some form of opencut or strip mining had been used in 20 U.S states; about 23% of all bituminous coal production and a third of anthracite production came from surface mines. In Great Britain about 5% of total coal production was from opencast mining.

In strip mining, large power-operated mechanical shovels, some of which can lift 35 tons at one bite, remove the overburden (earth and rock above the coal seam), drilled and blasted into fragments to facilitate removal. The shovels or draglines deposit this mass of limestone, shale and earth and rock in ridges paralleling the contour of the outcroppings of the coal. Once this overburden is removed and set aside, the surface of the exposed coal seam is cleaned by mechanical scrapers and revolving brushes. A smaller mechanical loading shovel with a capacity of five tons picks up the coal and deposits it in motor trucks or railroad cars which transport the mine-run coal to the cleansing and sorting plants, tipple or breaker—depending on the type of coal—where it goes through a final process.

Rehabilitation of Land Following Surface Mining.—Surface or strip mining necessarily overhauls the landscape. Most of the area from which coal is taken is submarginal land and not too valuable for farming purposes. Furthermore, the aggregate area affected is small, indeed, when measured against the effects of soil erosion and depletion of agricultural fertility, even in ordinary farming areas. However, land rehabilitation programs were adopted, especially in the United States, following the removal of coal. Methods were developed to reinstate the upturned earth or spoil banks, as they are called, into good land which eventually attains productivity.

About 190,000 ac. of land had been surface mined of coal by mid-20th century in Arkansas, Kansas. Illinois, Indiana, Iowa Kentucky, Missouri, Ohio, Oklahoma and Alabama. Of this total, 56,000 ac. supported satisfactory stands of grasses, shrubs and legumes. About 52,000 ac. had natural or planted forests, and about 5% of the acreage represented soils too toxic for revegetating properly.

IV. COAL MINING IN GREAT BRITAIN

Special Methods of British Mining.—No two collieries are exactly alike in British coal mines. Most of the coal seams are "pitching," that is, they are not horizontal or flat as are many of the seams in U.S. mines, but run up and down hill. Several coal seams are often found, one atop the other, and in many instances each seam has a different quality of coal. The United States has multiple coal seams in some of its mines; but generally speaking because of its greater wealth of coal, only the more convenient seam is mined, whereas in Britain the attempt is made to get all of the coal out once an area is reached. Seams are much thinner than in the United States and depths of mines are much greater Because of the greater depth (many are below the normal water level), English mines are drier than those of the U.S.

Since each colliery presents its own problems of production, according to the thickness of seam, inclination and depth from the surface, type of roof and floor and proximity to other workings no general statement can be laid down about the common or usual method of producing coal in all British mines. Different machinery from that employed in the U.S. must be employed. The use of compressed air for running locomotives, picks and practically all of the mining machinery underground is common to the British mines, although electricity was beginning to be used at mid-20th century.

As mentioned earlier, the most general method for producing coal in Britain is by longwall working. The second is the bord-and-pillar or pillar-and-stall system.

Because of the pitching seams in British mines, production by longwall working proved the easiest. Graham R. Bamber in his "Coal Mining and Miners Today," included in *The Secrets of Other People's Jobs* (Odham's Press Ltd., London, 1944), describes both methods as follows:

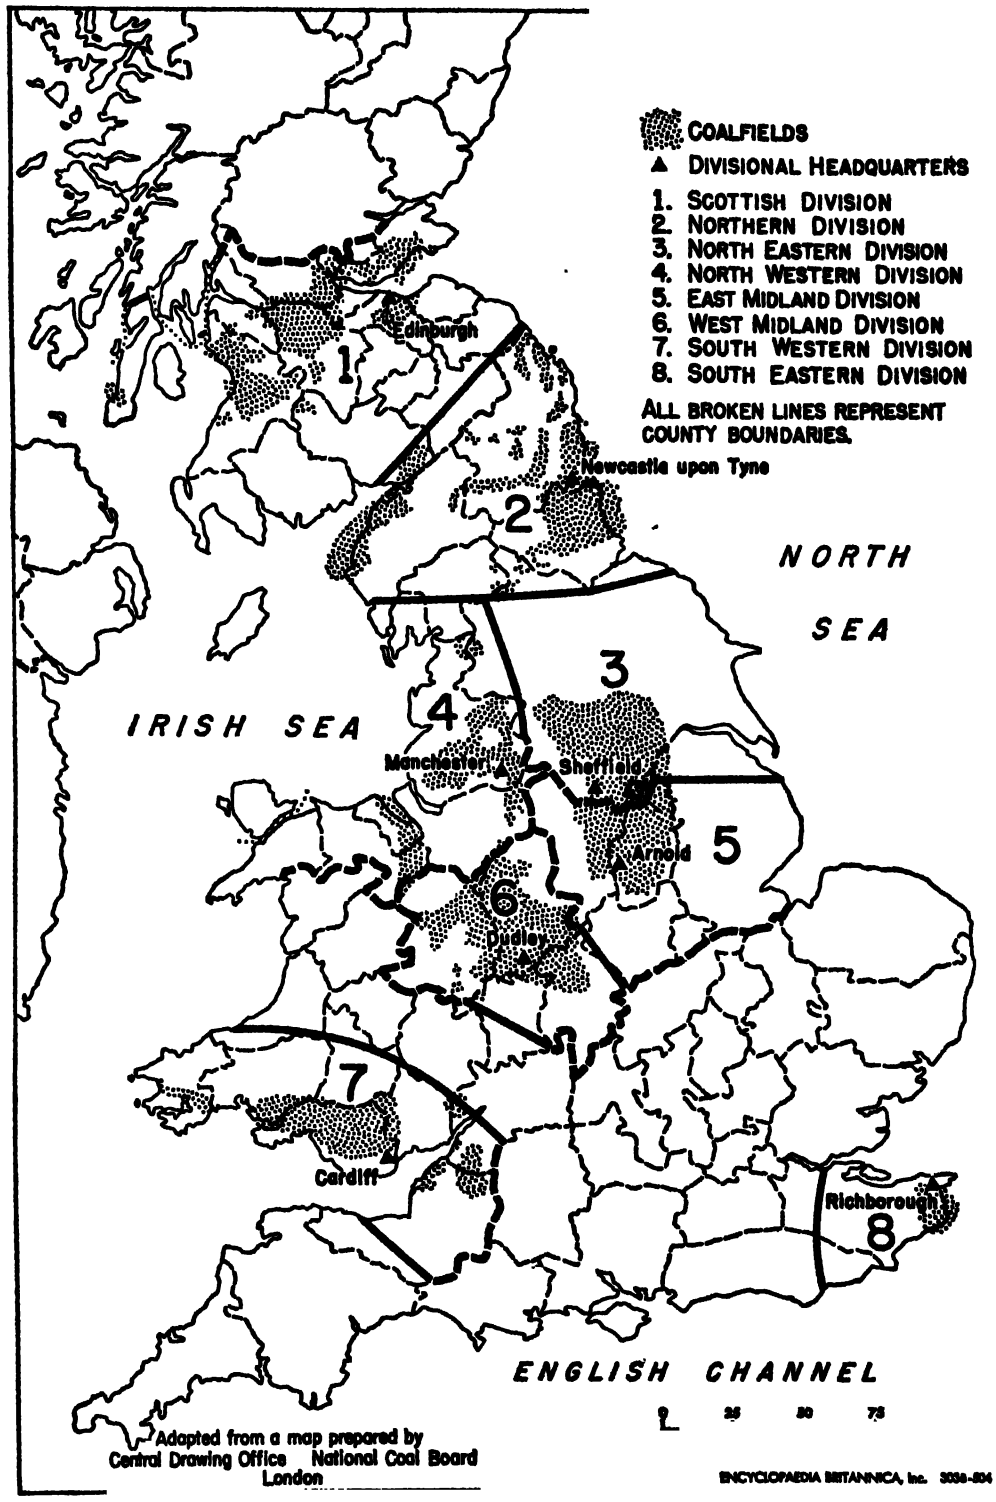
We keep a coal face, perhaps 200 yards long, which advances a fixed distance each day—it might be anything up to 6 ft.—and a collier is stationed at intervals to win and fill out the coal.

Main Gate Road.

The coal is brought away down a main gate road, leading from the middle of the face, and at each end of the face another road called a tail gate affords an alternative means of exit, allows for materials to be taken to the face, and provides for a ventilating circuit up through the gate road, along the face, and back through the tail gates and return roads. The other method is called bord-and-pillar working, and is used in broken, difficult ground and when mining under built-up areas. The seam is cut up by a series of longitudinal and transverse roads into squares, something like a gigantic chessboard, and these squares, or pillars, are then stripped as far as possible, but leaving enough coal to support the roof. This coal, of course, is lost if the surface has to be supported above, but the pillars are removed in strips and the surface let down if the support is not required.

In the bord-and-pillar (also called pillar-and-breast) system, the narrow roads or headings at the bottom of the underground mine are cut at right angles from the main road of the floor of the mine, and at intervals of about 100 yd. from each other. Twenty yards up a heading a miner begins to open his stall; another miner does the same 20 yd. farther on. Both men make the opening from the heading very narrow at first. Gradually they broaden it out toward each other until the two stalls meet. Behind them, standing between the two entrances is a block of coal called the pillar. This is left as a support for the roof.

Side by side in their stalls the two miners work forward, each cutting a breadth of ten yards of coal from the face. They work on like this for 50 yd., no farther, because 100 yd. down the main road is another heading from which other miners are working stalls toward them. On one side of the one man, between his stall and the main road, is a block of coal 20 yd. thick. There is a similar block of coal on the far side of the other man, between him and the next pair of stalls. Each miner now begins to cut away ten yards' breadth of this coal, working backward toward the entrance of his stall. The two men do this until they are level with the pillar left between the entrances. Thus, between the entrance of one stall and that of another stall stands a pillar of coal 20 yd. broad and of about the same thickness.



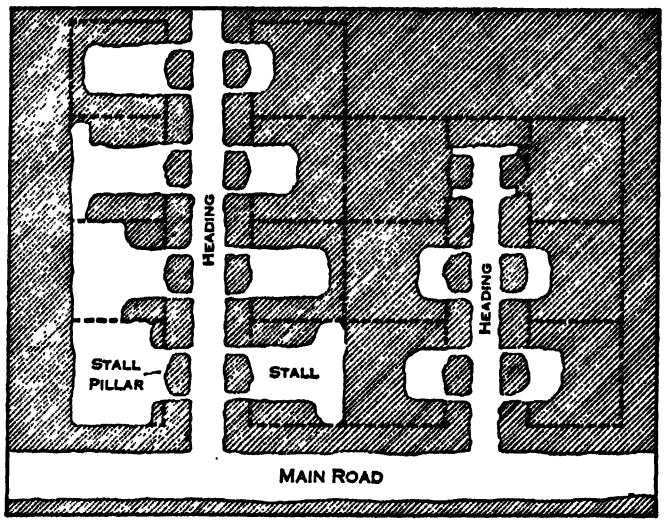


FIG. 2.—THE BRITISH COALFIELDS: PLAN SHOWING THE DIVISIONS OF BRITAIN'S NATIONAL COAL BOARD

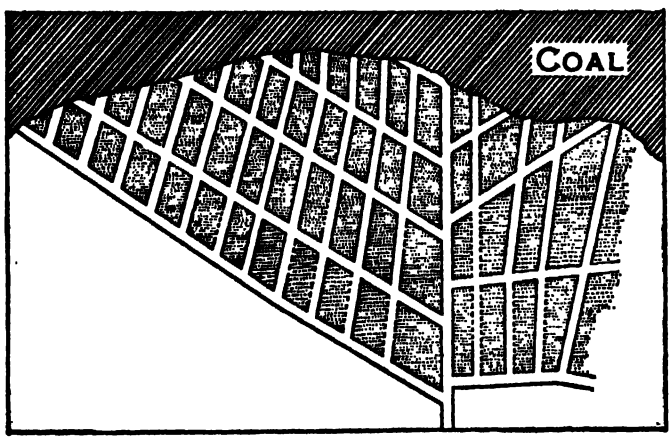
In the longwall method of underground mining, the headings are not cut at right angles from the main roads but are made diagonally. When a heading has been made from the road, a miner starts work at the corner where the road and heading meet. As he cuts away the coal he supports the roof behind him with props, and also with piles or chocks of the rock and shale which come away with the coal. Meanwhile narrow roads called gates have been cut at intervals, connecting the heading with the main road. In these gates other men set to work; as each man works forward he comes in time to the gate in front of him, where he stops. In this method of work all the coal is got out at once, and no pillars are left as is the case in the bord-and-pillar method.



BY COURTESY OF THE OXFORD UNIVERSITY PRESS

FIG. 3.—BORD-AND-PILLAR METHOD OF MINING

Sometimes work is begun at the far end of the heading, and the men work backward toward the main road instead of working from it. This is called longwall working back or long wall retreating. Although the roof is supported while the men are working near it, it is allowed to sink or settle gradually as they leave it behind them. All the coal is got out at once in this method.

In different mines or pits there are variations employed of both the longwall system and of the bord-and-pillar system. But in essentials, the methods described above constitute the general techniques employed in the two most popular production methods in Great Britain.

FIG. 4.—LONGWALL METHOD OF MINING

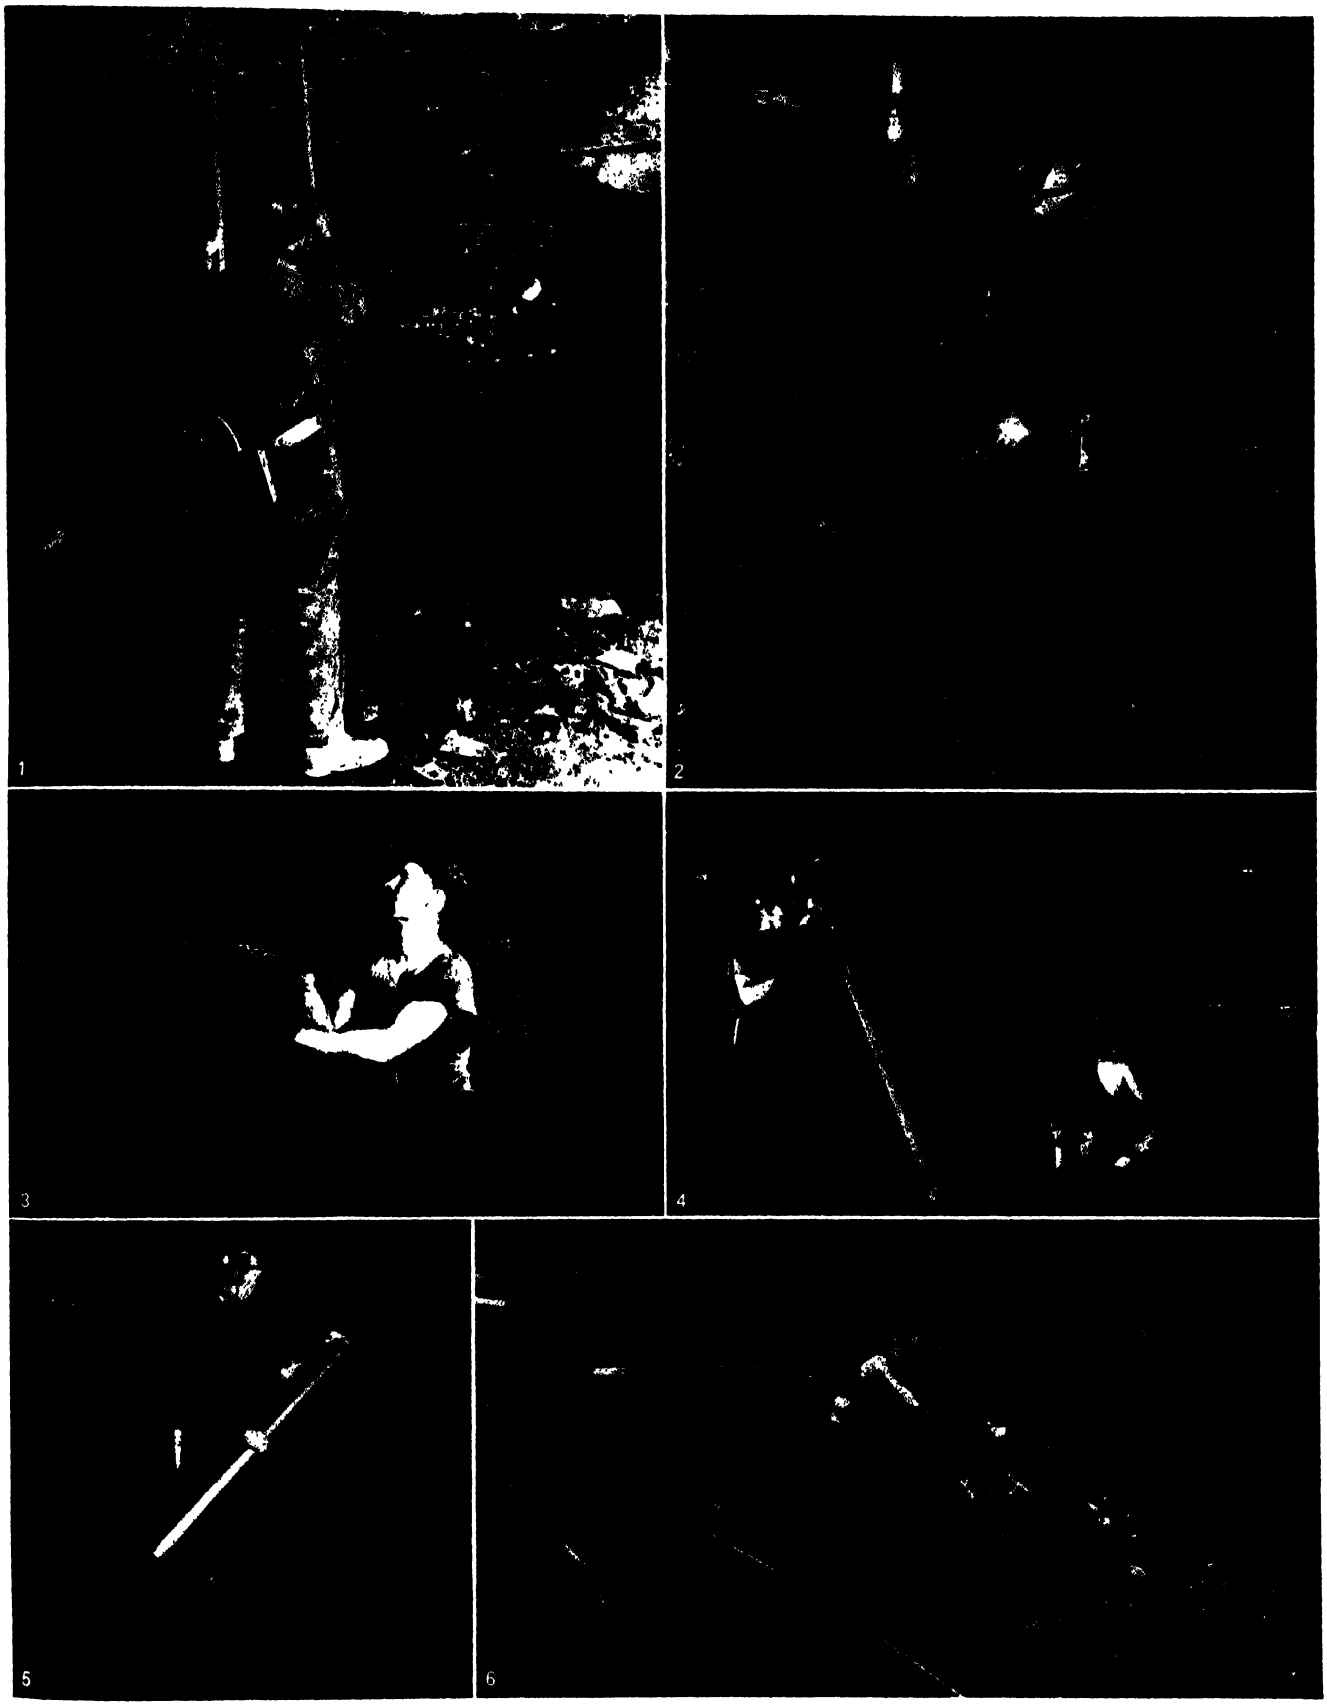
Nationalization.—In Sept. 1944, because of the serious drop in coal output and the shortage of manpower in the mines, the British government set up a committee of mining experts to recommend means of bringing the mines up to full efficiency. The Reid committee report, published in March 1945, dealt only with technical problems, but it was clear that if the committee's plans for modernizing the mines and putting the best kinds of mechanization into them were to be carried out, the whole industry would have to be reorganized. The government approved all the proposals of the committee. On July 12, 1946, the Nationalization of Coal Mines act was passed, and on Jan. 1, 1947, about 1,500 British collieries formerly owned by about 800 private organizations or individuals were taken over by the newly constituted National Coal board.

The whole country was divided into eight divisions and 48 areas. Each area averaged more than 4,000,000 long tons output of coal per year. The coal board, located in London, consisted of a chairman, a deputy chairman and various members representing labour, finance, manpower, reconstruction and planning, etc. The board altogether comprised nine persons. In each of the eight divisions there was a divisional board with its chairman and its functional directors patterned after the national board in London. In each of the eight divisions there was a general manager, responsible to the divisional board.

V. COAL MINING IN THE UNITED STATES

Mineable seams in the United States vary in thickness from 2 to more than 90 ft., but most production comes from seams 3 to 6 ft. thick. In the two foremost coal states, the seams at mid-20th century averaged 5.2 ft. (West Virginia) and 5 ft. (Pennsylvania). Montana, with America's thickest coal seams, averaged 16.8 ft., and Wyoming had 12.8 ft., with one mine in the latter state having a 90-ft. coal seam. Seams of great thickness are not always the sources of the best coal for power purposes, however. The coals are likely to be geologically young and inferior for heating purposes.

The average depth of vertical shafts in U.S. underground mining is 190 ft.; the deepest vertical shaft at mid-20th century was 839 ft. in New Mexico. The predominant type of mine opening in the U.S. is not a vertical shaft but rather a slope entry, inclined or declined to the coal bed, or a drift entry. About one-fourth of all U.S. coal produced in deep mines came from mines with vertical openings or shafts. This portion increases only when the seams best adapted to slope mining are exhausted, as is the case with Great Britain, where practically all coal mined is produced at shaft mines. Shaft mines in Britain, as has been noted, are much deeper than those in the United States, averaging 1,167 ft.



The national demand for both bituminous and anthracite coal in the U.S. rises and falls in conformance with general prosperity. For example, the disinflation of 1949, added to work stoppages, made the coal output of the first six months of 1949 about 10% behind the same period in the year preceding. Dieselization of railroad motive power was also having its obvious effect. Competitive fuels—natural gas, oil, etc.—were making their inroads on the home heating market, and general industrial activity was slackening, with fuel oil in supply at substantial price cuts. Retail prices of coal went up because of increased wages and a royalty tax for the miners' welfare fund. Thus the price differential between coal and gas became progressively smaller, with coal, usually the cheapest of all fuels, beginning to lose its economic advantage.

Original Coal Reserves by States.—Table II, showing original coal reserves in the United States by states, is based on U.S. geological surveys and, with respect to West Virginia and Pennsylvania, estimates of the state geological surveys. These figures do not measure the amount of coal that would be recoverable by existing methods of mining. Some scientists estimate that the amount of recoverable coal is 50% of the estimated reserves, while others put the percentage figure even lower.

Thirty one states and Alaska have deposits of commercially mineable coal. The area of continental United States underlain by coal equals 11% of the total area or roughly 340,000 sq.mi. Reserves equalled approximately 21,000 tons per capita at mid-20th century. About 29,332,000,000 tons of coal had been taken out of the ground, of which 23,459,000,000 tons (83.4%) were bituminous and 4,873,000,000 tons (16.6%) were anthracite. For each ton removed, there remained 104 tons still in the earth, including that in suspended or worked-out mines, on the basis of the deceptively large geologically inferred reserves.

Coal at mid-century was the largest in physical volume among all U.S. commodities, representing also the largest single item (one-third) of railroad freight haulage. Its total tonnage was approximately three times that of U.S. grain crops, and five times that of iron ore. Annual dollar value of mined coal exceeded the aggregate of iron ore, gold, silver, zinc, lead and other metals.

In 1860 the U.S. was producing 20,000,000 tons of coal a year, almost half being anthracite for home heating. Production almost doubled thereafter in each decade and was 111,000,000 tons in 1890; it doubled again to 212,000,000 tons in 1900. A 1918 output of 580,000,000 tons of bituminous lapsed to 569,-

000,000 tons in 1920 but in 1944, during World War II, the bituminous output reached a new high of 620,900,000 tons, which was exceeded in 1947 by another record of 631,000,000 tons. U.S. anthracite production reached a high of 62,181,409 tons in 1944.

Number of Men and Days Worked.—In 1920, 9,000 U.S. bituminous mines employed 640,000 miners; the industry expanded until in 1923 the mining force was 705,000 men. In 1948 the bituminous mines employed 435,000 and the anthracite approximately 75,000. The declining trend of the labour force was due primarily to replacement of manual labour by machines.

In 1935–39, the average number of days worked per year was 182; during the wartime emergency of 1944 this number rose to 278. In 1946 the figure was 214 days; in 1947, 234; in 1948, 210; and in 1949, 188. Strikes called by the miners' union in 1948 and 1949 accounted for the falling-off in working days during these years.

*Based on estimates made by Howard N. Eavenson, *The First Century and a Quarter of American Coal Industry*, 1800–1885; U.S. Bureau of Mines, 1886–1948. †Including pillars left and coal lost in worked-out mines.

Preparing Coal for Market.—In earlier days, before surface preparation plants for cleaning, sizing and washing coal came into vogue, the consumer received his coal as it came from the mine; labourers who did the loading underground picked out such impurities as shale which caught their eyes. This run-of-the-mine coal was a conglomerate mass of fines, small, medium and large, as they emerged from the mine and were loaded into railroad cars without any sorting or any processing. When loading machines came into use, the process of dumping coal into railroad cars was speeded up, and most if not all of the impurities stayed in.

Different types of consumers and varying types of coal-burning mechanisms inevitably began demanding particular sizes of coal.

The density of coal is less than that of the rocky impurities embedded in it. Natural impurities can be removed therefore in large part by gravity processes. In the case of underground mines, certain types of hoisting machines lift the coal from the bottom of the shaft to the surface. One of the most common hoisters is shaped like a cylinder and cone. In this type the skip for hoisting coal and the cage which takes the miners up and down are balanced to equalize the load on the electric motor as the cable is winding on the drum. Seven or more tons can be handled on the skip in a single trip. Some of these hoists reach a speed of 3,000 ft. per minute. Powerful hydraulic brakes operate automatically in case of accidental shutoff of power. In drift mines, trains sometimes numbering 40 to 60 or more cars are hauled by locomotives to the preparation plant. In a slope mine the cars may be discharged on a conveyor belt for removal to the outside or may be pulled up the slope with

a rope and hoist. Coal produced by surface or strip mining may be taken by truck or train to the near-by processing plant.

In anthracite mining, the cleansing or preparation plant is called a breaker, in bituminous a tipple. The former got its name from the fact that coal is broken, sized and cleaned there; the latter because cars filled with coal are tippled or dumped to the top of the cleansing plant. Inside the tipple or breaker many types of machines clean, wash and break the run-of-the-mine coal and separate rock, slag, slate and other impurities. Washing devices may be in the general form of inverted cones, inclined troughs, or tanks divided into a number of cells or compartments called jigs. In the cone method the separating media are sand and water. The coal floats off the surface while the slate, rock and other impurities, impelled by gravity, sink to the bottom. In the jig method raw coal is fed into the washer, which is filled with water, while compressed air comes up from the bottom to agitate the mass. This causes the material to separate into layers of different densities; the flow of compressed air is regulated so that the heavier refuse sinks to the bottom of the washer, while the clean coal and the middlings or secondary grades come out at the top. The middlings are as carefully prepared as the best grades. They are conveyed to other washers for further cleaning and the clean coal is then conveyed to shaking screens where it is separated into various sizes for the market.

For obtaining the finer sizes of coal, a table method is used. The raw coal is fed to the end of a sloping reciprocating table and becomes separated, because of its specific gravity, as it moves across the table in a medium of water and rising compressed air. In the water processing of coal, the coal floats as the impurities sink in what is called the wet process of cleaning. Chemicals are often used in the water to render the separation more efficient. In the dry cleaning process, air currents are used in lieu of water.

In the wet method, larger lumps travel over picking tables where skilled sorters remove rock and slate. Shaking screens of various mesh sizes separate the coal into standard sizes. An average of ten tons of water is used for each ton of prepared coal. The shaker screens are a series of perforated plates, one over the other, with the upper plate having the largest perforations and the smallest in the bottom plate. The holes in these shaker screens are of different sizes; in the case of anthracite coal, for example, are the following commercial sizes: grate, broken, egg, stove, nut, pea, buckwheat, rice, barley, no. 4 and no. 5, in the order of largest to smallest. No. 5 anthracite has a test mesh round of $\frac{5}{64}$ in.

In bituminous industries following World War II, tipples with modern types of cleansing and washing machinery began producing coals tailored to suit particular fuel needs. In anthracite breakers were large grinding machines, in which huge steel rolls broke the cleansed coal into the proper sizes for customer needs, from grate coal to the smaller sizes used for steam purposes. After cleansing and sorting, some mines spray the coal with oil to decrease dust. A company may trade-mark its coal with a colouring matter or by some other method.

In 1936 only about 26% of U.S. bituminous production came from mines having cleaning plants, ten years later the proportion had grown to 37%, with the technique constantly improving. The relationship of mechanical loading to the cleaning plant was apparent from the fact that in 1947 about 53% of all bituminous machine-loaded underground passed through plants equipped with mechanical cleaning devices. Only 18% of hand-loaded bituminous coal underwent that process. In 1947 about 30% of the strip mine tonnage had access to the most modernized cleaning plant facilities.

At mid-20th century there were about 2,200 coal trade names, many registered in the United States patent office; others were registered in the form of a design on booklets and stationery. Some sample trade names were as follows: Anchor Coal; Aztec; Beacon; Big Horn; Black Diamond; Blu-Glo; Black Beauty; Champion; Chanticleer; Chinook; Clinchfield; Colored Coal (red); Consol; Diamond Glo; Dixie Star; Enos; Everglow; Fire Chief; Glocoal; Green (colour); Grey Eagle; Hanna; Hedlite; Hiawatha; Imperial; Inferno; Jewell Pocahontas; Kentucky Jewell; Kincaid; Lehigh Valley; Lone Star; Maiden; Majestic; Marianna; Maumee; Meltwell; Monarch; Mountaineer; Natona; Norseman; Old Abe; Old Ben; Orient; Pilot; Pine Valley; Power King; Premium; Quick Heat; Randall; Raven; Red (colour); Red Cedar; Red Ember; Red Head; Red Jacket; Roberta; Royal Smokeless; Ruby Glow; Scarlet Flame; Silver Shield; Sky Chief; Southern Belle; Stonega; Sun-Glo; Tennessee Jewell; Tiger; Velva; Violet; Virglow; Volunteer; Vulcan; White Flame; Winding Gulf; Wingfoot; Yellow Jacket; Yellow Glo; Zulu.

Transportation.—About four-fifths of all bituminous coal mined in the U.S. is loaded into railroad cars or river barges at the preparation plant. Most of the remaining fifth is loaded into trucks to be transferred to freight cars or barges at sidings or docks. The rest—perhaps one-twentieth of the total—is used at the mine, made into beehive coke or carried on conveyor belts to a nearby place where it is used. Anthracite coal is handled much the same way in the United States as bituminous except that the proportions are different. No anthracite coal leaves its mining areas on river barges.

Historically, the coal and railroad industries had a unique interdependence; each was the other's best customer. Traditionally the railroads were the largest coal-consuming industry, though primacy was later taken by the electric power and light industry.

Movement of coal by truck directly to the consumer increased somewhat in the U.S. during and after World War II. In 1939, about 7.5 tons of 100 produced went to market by truck, whereas in 1947 about 8.9 tons moved by truck, with the percentage in later years somewhat greater. In 1947 about 30,000,000 tons moved from bituminous mines by inland waterways, either from on-the-spot water loading or after intermediate trucking or short distances by rail hauling; in 1939 this proportion was 6%. In 1948 the seagoing movement amounted to 32,000,000 tons of bituminous, of which 14,000,000 were for export. In the same year coal exports via Hampton Roads, Va., were 30% of the total exports to all countries including Canada. Bituminous coal exports through the port of Baltimore, Md., accounted for 8% of the exportation, Philadelphia, Pa., 1%, and New York city only 0.03%. Of the total exported tonnage to Canada, 52% was received via Lake Erie ports. Canada remained the predominant out-of-country consumer of U.S. coal.

About 61,000,000 tons, or 10% of U.S. bituminous output, moved in 1948 over the Great Lakes to markets in the northwest and Canada. About 55,000,000 tons passed through ports along Lake Erie; 4,000,000 tons through Lake Ontario ports and 2,000,000 from Lake Michigan piers. After 1942 the movement through Chicago area ports on Lake Michigan grew substantially. Lake steamers carrying this coal were capable of hauling as many as 13,700 tons of coal in their 35 or more hatches and were sturdy enough to make ocean voyages. Electric unloading shovels at Duluth, Minn., or Superior, Wis., were able to pick up from 8 to 15 tons at one bite. These were emptied into hopper cars or gondolas, moving out with rapidity the moment each was filled, with an empty replacing the loaded car.

Markets.—Consumption of 96,000,000 tons of bituminous coal by U.S. electric utilities comprised 18% of that nation's output in 1948. Steam-generated electricity is produced largely from coal, fuel oil, natural gas, wood and waste. Percentagewise, between 1920 and 1948, coal produced variously from 47.5% (in 1932) to 57.1% (in 1925) of the total generated in the nation. In 1948, the coal proportion was 54.1%. By comparison fuel oil accounted for between 2.4% (in 1927–28) and 6.8% (in 1924); in 1948 it was 5.9%. The proportion fuelled by coal was relatively stable, while natural gas expanded from 1.5% of the nation's total in 1920 to 10.7% in 1948.

The efficiency of coal utilization in electricity generation grew markedly. In 1914 a ton of coal produced an average of 525 kw.hr.; in 1946 a ton produced 1,550 kw.hr.

Consumption of bituminous alone for all purposes by rail

roads totalled 99,000,000 tons in 1948, or 17% of the national production. The maximum of bituminous coal's importance as railroad locomotive fuel was reached during the first quarter of the 20th century, when it was 86–92% of the total coal equivalent. Oil-burning steam locomotives came into significant usage, and later the diesel-electric. From the 1935–39 period diesel oil use grew from less than 1% to nearly 15% of the total locomotive fuel. For passenger-train service the diesel-electric locomotive has attained a real popularity. To offset this loss by a competing fuel, a coal burning gas turbine locomotive was designed and first demonstrated in June 1949.

TABLE V.—*Use of Bituminous, Anthracite and Other Fuels and Power in the U.S.*
(Coal, thousand tons; petroleum, thousand barrels; natural gas, million cubic feet; hydroelectric power, million kilowatt hours; and trillion B.T.U.)

Year	Bituminous	Anthracite	Petroleum products	Natural gas	Hydroelectric	Total bituminous coal equivalent*

*Total of bituminous coal and anthracite plus petroleum products, natural gas and hydroelectric power converted to the equivalent of bituminous coal.
Source: Based on data published by the U.S. Bureau of Mines and the Federal Power Commission.

Anthracite is used primarily in the United States for home heating purposes. Of the estimated total production of 50,137,000 net tons in 1948–49, 31,995,133 tons or about 59% were in domestic sizes used for heating purposes primarily; 22,058,837 tons, or 40.8%, were in steam sizes, used for heating and other commercial needs. The iron and steel industry in 1948 used 2,500,000 tons of anthracite.

Of the total 1949 output of U.S. bituminous coal—460,000,000 tons—almost half or more than 215,000,000 tons was used in manufacturing plants for power purposes and for construction. Approximately 100,000,000 tons were burned in coking ovens to make steel for building uses, locomotives, cars and tracks, bridges and automobiles; 8,000,000 tons were used in rolling mills; another 8,000,000 by cement plants; and 101,000,000 tons for all other manufacturing purposes. Retail dealers took 90,000,000 tons for distribution to about 19,000,000 homes and to thousands of small industries. The railroads used 73,000,000 tons and electric utilities ac-

counted for 80,000,000 tons. Exports of bituminous were about 27,000,000 tons. The total output in 1949 was considerably less than normal because of widespread strikes.

VI. HAZARDS OF MINING AND MEASURES OF SAFETY

The greatest hazards in coal mining are falls from the roof at the working face. U.S. bureau of mines statistics show that 50% of all coal mining fatalities and 30% of serious accidents are due to top falls. In Great Britain roof falls and haulage account for 50–55% of fatalities and accidents in the first case, and about 25% in the second; *i.e.*, the moving vehicles (called tubs) and the ropes underground. Mechanized productivity entails rapid transit of coal by trainloads from the point of extraction to the tipple or breaker. In the decade 1939–48, haulage accidents accounted for 19% of the bituminous coal mining fatalities in the U.S. Explosions of firedamp and coal dust came next, causing 10% of the industry's fatalities. The proportion varied widely; it was as high as 24% in one year and as low as 3% in 1944. In one of the safest years, 1948, there were 11 ignitions of coal dust and gas reported.

Another source of accidents is the use of explosives in underground mining. Safety instructions and the manufacture of safer types of explosives, however, reduced the toll appreciably. Fatal accidents caused by explosives in bituminous mining per million man-hours for the five-year period 1906–10, inclusive, were 0.1446, and only 0.043 in 1941 and 0.026 in 1942. The use of electricity underground tended to increase accidents, especially in gassy mines, where electrical equipment must be kept in proper working condition. In the U.S., 63 fatalities caused by electricity underground occurred in 1930; in 1944, only 26 such accidents took place; and in the latter year more than 72,000,000 more tons of bituminous were mined than in 1930.

Last among the hazards of coal mining come shaft accidents. Percentagewise the number of fatal accidents occurring in shafts in bituminous and lignite mines, however, was reduced more than in the case of any of the other principal causes. In 1906 73 men lost their lives in U.S. shaft accidents; by 1943 there were only five such fatalities. This reduction was effected largely by improvements in hoisting equipment, safeguards at the collar of the shafts and at shaft landings and in cages; in improved methods of handling cars on and off the mine cages, and of handling men in hoisting shafts and slopes.

In Great Britain, the National Coal board reported 470 deaths and nearly 2,400 serious injuries in 1948. Falls from the roof were still the commonest cause of accidents; underground lighting was still a serious problem, and experiments were being tried with fluorescent lighting. Miners used more cap lamps; of about 500,000 lamps in use during 1948, about 150,000 were replaced by more modern types. Several roadway lighting systems were put into the collieries, consisting of tungsten filament and tubular fluorescent discharge lamps, with specially designed fittings. More whitewashing of the roadways had also helped improve lighting.

Dust disease or pneumoconiosis was still a major problem in Britain; in 1947 3,779 cases were certified, of which 2,795 were in south Wales.

Safety Measures.—This cumulative increase in safety was the result of many safety devices and precautions. One of the obvious first considerations is to provide proper ventilation in the mines. At least one giant fan is installed in the fan house near the mouth or mine opening. This blower forces a continuous flow of pure fresh air into all parts of the mine and drives out the foul air. The weight of air circulated daily through a mine has been estimated at more than 12 times the weight of the coal mined each day. In addition to providing fresh air the blowers serve another very highly important purpose—they dilute and render harmless accumulations of dangerous gases. Wherever coal is found underground there is likely to be methane gas, sometimes called firedamp or marsh gas. This gas cannot be detected by ordinary methods and is highly inflammable. A product of the ageless decomposition of the organic matter in coal, it can sometimes be heard working in a coal seam. The sound is like the faint humming of bees.

A modern mine consists of a carefully planned system of air passages, ducts and boarded safety gates which fit snugly in the labyrinth of tunnels. The gates open and close automatically when the occasion demands—such as the passage of a long line of cars loaded with coal. Mine foremen and safety engineers check the construction of the overcast or ventilating passages cut into the rock above the coal seams from time to time to see that the ventilating currents pass through freely. Sturdy ceiling beams support reinforced concrete slabs where the ventilating overpass areas occur, carrying intake air over the mine haulageway, and serving also as a giant exhaust duct. Temperatures range from 68° to 72° F.

On account of the danger of possible gas explosions, no equipment requiring use of an open flame is permitted by law in U.S. or British mines. There are strict rules against smoking in mines, especially gaseous mines, where miners are even forbidden to carry matches underground.

Miners are required to wear safety shoes of heavy leather with a piece of curved steel under the toecap. Eyes are protected by heavy safety goggles. A specially designed stiff hat, light in weight but very strong, is intended to save a man's head from many bumps against low ceilings or roof props and to protect him from pieces of falling slate, rock or coal. Every miner's helmet is provided with an electric bulb headlight connected with a compact dry cell battery strapped to his side or back. Formerly candles were used to light British mines, until Sir Humphry Davy's invention (1815) of a safety lamp consisting of a fine wire gauze enclosing the flame to keep it from coming in contact with mine gas. Later this was replaced by a flickering oil lamp and still later by the carbide lamp.

Everywhere in the mine, aboveground or underneath, the miner is reminded of the need for safety. The health and safety division of the United States bureau of mines, comprising three sections —safety, mine inspection and miners' health—carries on its work through hundreds of inspectors and safety instructors from 21 field offices throughout the United States. All states in which coal is mined commercially have state mining departments to enforce the state mining laws which are, as a rule, very rigid. All large coal companies employ safety directors, and the National Coal association in the U.S. maintains a safety division, as does the National Coal board of Britain.

A careful watch on all parts of the mine is made constantly. Upon starting the day's work the miner must first go to the lamp house, where he is handed his cap and lamp, the battery of which has been recharged and tested beforehand. Each worker has his individual number which is recorded and then hung up on a chart opposite the number of the room to which he has been assigned to work. The office staff aboveground thus knows his exact location at all times. U.S. miners generally work in groups of 20 to a section underground. On the walls of the office hang huge blueprints which show the mine workings in detail.

During the night, preparatory for the day shift, or the day if it be for the night shift, the fire boss and his assistants patrol and inspect all parts of the underground mine. By tapping the roof with special instruments they can tell where it needs support before the men are permitted to work in that part of the mine. Hundreds of thousands of timber posts are used annually in coal mines to support the roofs. In the more highly mechanized mines electric timbering machines are employed to raise the heavy ceiling beams automatically while other men set and wedge the posts.

A vigilant check is made for gas accumulations, and since firedamp or methane gas is odourless, tasteless and highly inflammable, special gas detectors are employed to discover the presence of this gas. These replaced the canaries formerly used for this purpose. A permissible flame safety lamp has two sets of fine wire gauze above the glass surrounding the flame, one inside the other so that it will not get hot enough to ignite either gas or coal dust. It is equipped with a magnetic lock that can be opened only in the lamp house on the mine surface. In good air the flame is clear yellow; if explosive gas is present a blue cap appears above it. The height of the cap indicates the amount

of gas present. In all properly run mines the fire bosses or inspectors examine a working place in the mine daily, sometimes twice daily, before the miners arrive, using either these permissible flame safety lamps or electrical gas detectors. If gas is found, ventilation is introduced at once to remove it. If the amount of gas is large, all power may be shut off until the section of the mine affected is made safe. When a room is rendered safe, chalk marks are made on the walls by the safety foreman or the inspectors.

In the better equipped mines all power is furnished by electric motors rather than by combustion engines. Painstaking care is taken in the construction of all electrical equipment to eliminate sparks that might set off an explosion. There are rigid requirements set by law which must be met before miners may use explosives to dislodge the coal from the working face. Power drills usually bore two holes of the same length simultaneously; a test is made for the presence of gas and then the explosive is carefully tamped into the holes. Only permissible explosives, first tested and approved in the U.S. by the bureau of mines, may be used. Previous cuttings of the coal must first be removed and loaded into cars before a shot can be made. This precaution is necessary in order to avoid dust explosions and possible injury to the men of the section. When all is in readiness, the miners retire to a safe distance, usually about 100 ft. away, and an electric current from a dry cell battery explodes the coal. In some mines compressed air, at a pressure of 10,000 lb. per square inch, is shot from a mechanism that looks like a rifle and replaces the explosive. The charge of compressed air is sent through a kind of tubing inserted in a predrilled hole; this kind of blasting is not only safer, but speeds production as well.

Some dust, containing combustible matter, naturally accumulates after blastings and cuttings, and at times these accumulations may prove dangerous. To counteract it, an ingenious chemical composition known as rock dust was developed and came into universal use in U.S. mines. This is a fine, whitish powder, damp in structure, the chief ingredient of which is limestone. Powerful electric blowers force it onto the walls and into the tunnels of the mine. This process dilutes the coal dust, cleans the air and avoids the possibility of an explosion. British mines use water sprays for dust control more than do the Americans.

Still other safety devices found in U.S. mines are the first-aid stations scattered at strategic places within the mines and designated by green lights. These are equipped with everything necessary for an emergency—convenient receptacles filled with picks, shovels and other tools, bags with rock dust, respirators, oxygen tanks on occasion and equivalent materials. Mines are also equipped with an intricate telephone system, connected finally with the office aboveground. At intervals of 60 ft. or less, dependent upon state regulations, manholes are provided along the main haulageways as places of refuge in emergencies. The open-top man-trip cars have gradually been replaced by all-steel cars, enclosed, electrically operated, and each carrying an average of 38 men comfortably and with complete safety. Some cars travel five miles and more underground to reach the working part of the mine.

VII. CHEMICAL BY-PRODUCTS OF COAL

There are believed to be more than 200,000 chemical by-products from bituminous coal alone. Aside from its obvious contribution to physical warmth and comfort (about one-sixth of all U.S. bituminous and three-fifths of all anthracite, are used for home heating), coal's principal by-product is coke, which makes possible the manufacture of steel. More than 54% of the electricity in the United States is generated from bituminous. From this coal is derived the tar and pitch for roofing and insulating materials. Highways are made possible through coal derivatives because macadam uses coal tar or pitch as binder for gravel and stone, and cement must have coal tar or pitch for expansion joints. In agriculture, coal helps develop fertilizers, insecticides, disinfectants, herbicides, fungicides, fumigants, preservatives, plant-growth regulators and food dyes.

The refrigerants—carbon dioxide for dry ice, and ammonia, and the synthetic in electric refrigerators—are coal derivatives. All edible dyes, preservatives and water softeners formed from ion exchange resins are bituminous derivatives. Synthetic rubber of the styrene type and that which comes from neoprene have, as basic raw materials, limestone, salt and coal tar. Paints and finishes have pigments, solvents and resins as ingredients, many of which are coal-derived.

Hundreds of medicines and antiseptics are produced from coal. Photographic films have sensitizing dyes added to the basic silver bromide in order to register colours other than blue and ultra-violet, and these dyes, a few of the 10,000 available, stem from bituminous. The coal-tar derived plastics which produce nylon films also help create extruded rattan, braided machinery packing, various types of tubing, rods, electric motor bearings, window screens, lampshades and kitchenware, electrical fittings and telephone receivers, jewellery and clock cases, aircraft parts and picture frames, phonograph records, shower curtains, raincoats, vanity cases and children's toys. Nylon or Lucite acrylic resin is the product of coal, air and water. Aside from uses in clothing, nylon is made into paintbrush bristles, parachute harness webbing, parachute shroudlines, heavy nylon rope, cargo parachute cloth and light nylon rope.

Table VI is a summary of the products of the carbonization of bituminous coal.

TABLE VI.—*Products of the Carbonization of Bituminous Coal*

- **Light oil**
  - Benzol
  - Toluol
  - Xylol
  - Solvent naphtha
- **Coal tar** (app. 50% is processed at distilling plants)
  - Road tars and refined tars
  - Creosote and tar acid oils
    - phenols
    - naphthalene
  - Pitches and pitch coke
- **Chemicals**
  - Ammonium sulphate
  - Sulphur
  - Phenols
  - Naphthalene

Benzol	motor fuel rubber paint, varnish, lacquer dye and dyestuffs chemical industry plastics pharmaceuticals disinfectants explosives	**Xylol**	rubber paint, varnish, lacquer dye and dyestuffs chemical industry plastics
Toluol	rubber paint, varnish, lacquer dye and dyestuffs chemical industry pharmaceuticals plastics explosives disinfectants	**Naphtha**	rubber paint, varnish, lacquer plastics
		Phenols	dye and dyestuffs chemical industry pharmaceuticals plastics explosives disinfectants soap
		Naphthalene	dye and dyestuffs chemical industry plastics explosives agriculture disinfectants soap

Some coal-tar derived synthetic medicinals:
acetanilide
acetylsalicylic acid (aspirin)
sulfanilamide
procaine
arsphenamine
phenobarbital
neocinchophen
neoarsphenamine
nicotinic acid amide
salicylic acid
sulfapyradine
sulfoarsphenamine
sulfathiazole
phenacetin
mapharsen
benzaldehyde
benzoic acid
ephedrine
hexylresorcinol
epinephrine
phenophthalein
cinchophen
salol
chloramine T
theobromine
vitamin K
pyradoxine (B6)

Some coal-tar derived perfume materials:
amyl salcylate—clover, orchid
benzaldehyde—bitter almond
benzophenone—rose
benzylacetate—jasmine
cinnamic acid—balsam
cinnamic alcohol—lilac, hyacinth

TABLE VI.—*Products of the Carbonisation of Bituminous Coal (Continued)*

cinnamic aldehyde—cinnamon
coumarin—tonka bean, new mown hay
isoamylbenzylether—gardenia
methylanthranilate—orange blossom
musk zylol (DuPont)—natural musk
nitrobenzene—almond
phenylacetic aldehyde—hyacinth
phenylacetic acid—honey rose
phenylethyl alcohol—rose
salicylaldehyde—meadowsweet

Coke and By-products

Coke
- metallurgy
- retort carbon
- foundry
- coke breeze
- domestic fuel
- electrodes
- graphite
  - lubricants
  - crucibles
  - electrodes
- producer gas
- water gas
  - fuel
  - synthetic chemicals
  - motor fuel
- carborundum
  - abrasives
- calcium carbide
  - fuel
  - calcium cyanamide
    - fertilizer
    - explosives
  - acetylene

Ammoniacal liquor
- ammonium sulphate
  - fertilizer
- pyridine
- ammonia water
  - ammonia salts
  - nitric acid
- anhydrous ammonia
  - nitric acid
- liquid ammonia
  - refrigeration

Middle (carbolic or naphthalene) oil
- Crude carbolic acid
  - Phenol
    - nitrophenols
      - picric acid
      - *p*-amidophenol
      - phenacetin
      - dye intermediates
      - developers
      - explosives
    - salicylic acid
      - salicylates
      - aspirin
      - methylsalicylate
      - salol
      - dyestuffs
      - preservatives
    - resins and plastics
  - Cresols or cresylic acids
    - antiseptics
      - lysol, creolin
    - resins and plastics
- Crude naphthalene
  - Naphthalene (refined)
    - phthalic anhydride
      - phenolphthalein
        - indicator and laxatives
      - phthalimide
        - anthranilic acid
          - flavouring, perfumes
      - anthraquinone
        - dyestuffs and intermediates
    - nitronaphthalene
      - explosives
      - naphthylamine
      - insecticides
      - dyes
    - naphthalene sulphonic acids
      - naphthols
      - dyestuffs

Heavy or creosote oil
- Crude carbolic acid—disinfectants
  - phenol
  - cresols
- Creosote oil—wood preservative

Green or anthracene oil
- Wood preservative
- Crude anthracene
  - Carbazole—dyestuffs
  - Phenanthrene—dyestuffs
  - Anthracene
    - anthraquinone—intermediates and dyestuffs

Light oil
- Benzene (benzol)
  - Halogenated benzene
    - dyestuffs
    - insecticides
  - Nitrobenzene
    - dye intermediates
    - developers
    - aniline
      - aniline salts
        - dye intermediates
        - dyestuffs
      - dimethylaniline
        - dye intermediates
        - dyestuffs

Pitch
- Soft
  - paving materials
  - waterproofing
  - insulating materials
- Medium
  - paints
  - metal protective coatings
  - roofing materials
  - waterproofing
- Hard
  - protective coatings
  - insulating compounds
  - electrodes
  - core compounds
  - briquetting
  - electrode binders

Pitch coke
- electrodes
- foundry coke

TABLE VI.—*Products of the Carbonisation of Bituminous Coal (Continued)*

- quinone
  - hydroquinone
    - photographic developer
  - phenylhydrazine
    - antipyridine
- Maleic acid
  - maleic anhydride
    - plastics
- Benzene sulphonic acid
  - phenol
  - dye intermediates
- Pyridine
  - denaturant
- Heavy naphtha
  - synthetic resins
  - coumarone resins
- Solvent naphtha
  - xylenes
    - dyestuffs and intermediates
- Crude carbolic acid
  - phenol
  - cresols
- Crude toluene
  - benzoic acid
  - toluene
    - nitrotoluenes
      - explosives
      - dye intermediates and dyestuffs
      - toluidines
    - benzaldehyde
      - flavouring substances
      - dyestuffs
      - perfumes
      - drugs
    - toluene sulphonic acids
      - antiseptics
      - chloramine T
      - saccharin

VIII. WORLD COAL RESOURCES AND PRODUCTION

Perhaps the most reliable of pre-World War I estimates of the total coal resources of the world was that compiled by the 12th International Geologic congress in 1913 and reported in the *Coal Resources of the World*. This report estimated the total known and probable world resources as 7,397,553,000,000 metric tons, of which the United States was credited with 3,838,657,000,000. Europe with 784,190,000,000, and other parts of the world with the remainder.

In 1936 the Reichskohlenrat (German National Coal council) of Berlin published a statistical review of the coal industry of the world, basing its estimates on the original figures of the 12th International Geologic congress, but revised in accordance with its own later discoveries and changes in boundaries of different countries following World War I. A summary of these statistics believed reliable for the period immediately preceding World War II, is found in Table VII.

TABLE VII.—*Coal Resources of Europe and the United States, Estimated to a Depth of 6,560 ft.*
(In millions of metric tons)

Country	Anthracite and bituminous coal		Lignite and brown coal	
	Known and probable	Known	Known and probable	Known
Belgium	11,000

*According to U.S. geological survey estimates in 1928, coal reserves in the U.S. to a depth of 1,000 metres were: 2,041,090,000,000 metric tons of coal and 852,317,000,000 metric tons of lignite.

Following World War II a re-estimate was made of coal resources in Europe, North America, Central and South America, Africa, Asia and Australasia. These statistics, appearing in the fourth *Statistical Year-Book* of the World Power conference, 1948,

are summarized in Table VIII.

In Table VII it will be noted that Germany had the largest estimated known and probable resources of any country in Europe, especially if its brown coal resources were also included. Germany's most important coal is the Ruhr coking coal, which has made that district—in proximity to the Lorraine iron ore deposits

TABLE VIII.—*World Coal Resources Estimated by the World Power Conference, 1948*
(In million metric tons)

	Coals	Brown coal and lignite			Peat
	Proved reserves	Probable total reserves	Proved reserves	Probable total reserves	Probable total reserves
Certain countries in:					
Europe	548,000	1,551,000	50,000	287,000	111,000
North America	42,000	2,115,000	20,000	951,000	13,000
Central and South America	2,000	1,000	..	..	..
Africa	9,000	206,000	..	..	..
Asia	11,000	1,097.000	..	4,000	..
Australasia	4,000	14,000	5,000	40,000	..
Total	616,000	4,984,000	75,000	1,282,000	124,000

—the most important producer of iron and steel on the continent. Great Britain comes second in coal resources, but actually has larger known coal deposits than any other European country. Poland has a great deal of bituminous. Then comes the U.S.S.R., although the actual facts about total Russian coal resources in both Europe and Asia were unknown at mid-20th century. France, Belgium and Czechoslovakia are next in importance, with relatively small resources, though what they possess is very important for steelmaking.

Coal occurrences in China are widespread, being found in almost every province and ranging from hard, dry anthracite to bituminous and lignite. The original estimate of the 12th International Geologic congress giving China coal reserves of 995,587,000,000 tons was challenged by geologists as an overestimation. In 1926 the Chinese geological survey offered a conservative estimate of 217,626,000,000 tons. Even such a figure would place that country as one of the ranking units in the world's coal reserves. Japan's coal reserves were estimated to total 7,869,000,000 metric tons.

There are appreciable deposits in India, New South Wales, the Union of South Africa and Australia, and variable coal resources in other countries. Canada possesses enormous resources

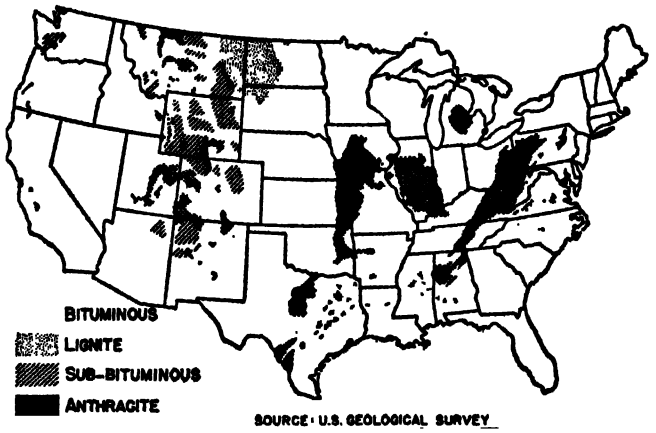

FIG. 5.—LOCATION OF U.S. COAL RESERVES

of coal in both the Atlantic and Pacific coastal regions and in the interior plains, comprising practically all kinds from lignite to anthracite. Distribution of actual and probable reserves is estimated at 1,234,269,000,000 metric tons, approximately one-sixth of the world's total.

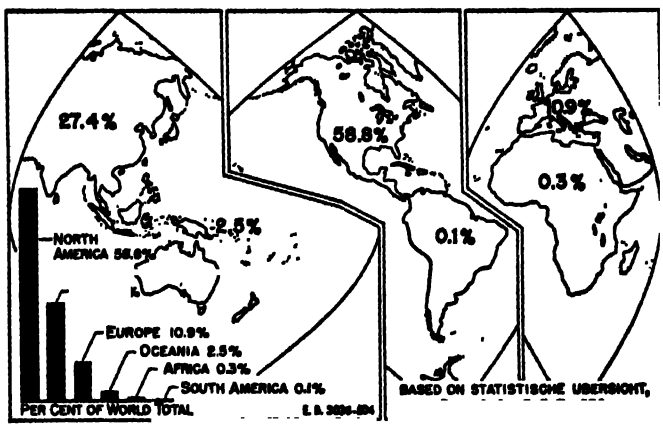

FIG. 6.—LOCATION OF WORLD'S COAL RESOURCES, BY CONTINENTS

PRODUCTION

The United States produced 34.8% of the world's coal in 1948, as compared with 43% in the years of World War I. Since the turn of the century, it had been the world's foremost producer—a position formerly occupied by Great Britain. It is worth noting at this point that Great Britain's output of 234,000,000 net tons in 1948 equalled the entire world production of 1868, when British production accounted for more than half the world total. By 1900 the British proportion had diminished to 30%, and in 1948 it was 12.5% of the total.

World production attained its record of 2,058,000,000 tons in 1942, but World War II brought it to a postwar low of 1,487,000,000 tons in 1945 (*see* Table IX). By 1946 the total had climbed back to about 1,629,000,000 tons, and in 1948 it approximated 1,620,000,000 tons.

Records of world production go back to 1868–69, when the output was 230,000,000 tons. Production grew consistently until the late 1920s, when it began to feel the effects of depression. By 1936, however, the general level of 1925–29 was regained.

World production figures for all coal-producing countries (1941–48) are shown in Table X.

COALBROOKDALE, a village and ecclesiastical parish of Shropshire, Eng., on the Western region railway route, 5 mi. south of Wellington. Pop. (1931) 1,417. The "dale" is the valley of a stream rising near the Wrekin and following southeast for about 8 mi. to the Severn. Its ironworks, founded in 1709 by Abraham Darby with Dutch workmen, were the pioneer attempt to use pit coal for smelting iron. The third Abraham Darby built the famous Coalbrookdale iron bridge (a cast-iron arch of 100-ft. span) over the Severn, which gives name to the neighbouring town of Ironbridge, which with a portion of Coalbrookdale is in the parish of Madeley (*q.v.*). There are also brick and tile works.

COALDALE, an anthracite-mining borough of Schuylkill county, Pa., 45 mi. southwest of Scranton. It is on federal highway 209, and is served by the Lehigh and New England railroad for freight. The population in 1950 was 5,230; it was 6,163 in 1940 by the federal census.

COALFISH (*Pollachius virens*), a fish of the cod family, with three dorsal and two anal fins, distinguished from the cod by its blackish colour, prominent lower jaw and very small barbel. It ranges from the Arctic ocean to the Mediterranean and grows to a length of about four feet.

COALING STATIONS: *see* FUELLING STATIONS.

COALITION, a combination of bodies or parts into one body or whole. (Lat. *coalitio*, from *coalescere*, "to grow together.") The word is used, especially in a political sense, of an alliance (*q.v.*) or temporary union for joint action of various powers or states, such as the coalition of the European powers against France during the wars of the French Revolution; also the union in a single government of distinct parties or members of distinct parties.

COAL TAR is the primary condensation product resulting from the carbonization of coal; *i.e.*, the heating of coal in the absence of air, at temperatures ranging from about 900° C. to about 1,200° C. It is a black, viscous, sticky fluid whose density is greater than that of water.

Manufacture.—The manufacture of coal tar and related products starts with the placing of coal in a chamber, and the

heating of it out of contact with air. The coal is thereby decomposed into volatile products and into a nonvolatile residue, coke. The volatile products are composed of condensable materials and noncondensable gases. As the volatile products are formed they are removed from the chamber and cooled, whereupon the water and tar are liquefied; these two substances; *i.e.*, water and tar, constitute the bulk of the condensable materials evolved during the decomposition of the coal. With the condensation of the water, a portion of some of the gaseous constituents which are more or less soluble in the water is also removed. After the complete removal of the water and tar, the gas is passed through water, or dilute sulphuric acid, which absorbs the ammonia present. Finally, the relatively clean, cool gas is passed through an oil or over activated carbon to remove such low boiling constituents as benzene, toluene, etc., which go to make up coal-tar light oils.

The temperature at which the carbonization is conducted, the type of equipment used and the nature of the coal carbonized determine the kind of tar and the quantity obtained.

The temperature of carbonization has more effect on the quality (kind) of coal tar and on the yield than any other single factor. So great is the influence of the carbonization temperature that coal tars are divided into high-temperature tars and low-temperature tars; those produced at carbonization temperatures from 900° C. to 1,200° C. are called high-temperature tars and those produced at carbonization temperatures from 450° C. to 700° C. are called low-temperature tars (*see* TARS, LOW-TEMPERATURE).

When coal is heated, in the absence of air, to a temperature of about 450° C., the coal begins to decompose and an evolution of gaseous products occurs. As these gases are liberated from the coal mass they come in contact with the walls of the carbonizing chamber before they escape and are condensed. If the walls of the carbonization chamber are at about 450° C., the gaseous products are not changed by coming in contact with them and the tar recovered from the gases is a true low-temperature tar, called a primary tar. If, however, as is the case in the commercial production of coal tar, the walls of the chamber are at a higher temperature, the gases evolved from the coal at 450° C. are altered when they come in contact with the hotter walls. The type of change which occurs at these hot walls, as well as the portion of the gases that undergoes change, depends upon the temperature of the walls and the length of time the gases are in contact with the hot walls.

Although it is customary to say that the coal is carbonized at a low temperature or at a high temperature, this is not strictly correct. The coal is not carbonized *at* a temperature but *to* a temperature. The initial decomposition of the coal takes place at about 450° C. As the carbonization progresses, the temperature of the decomposing coal rises. If the carbonization process is discontinued when the temperature of the decomposing coal mass reaches about 700° C., and if the gases do not come in contact with walls which are at a temperature above about 700° C., the tar recovered is a low-temperature tar. If the decomposing coal is heated to a higher temperature, 900° C.–1,200° C., further decomposition of the coal mass takes place; the gaseous products evolved at these higher temperatures are of a different nature from those evolved at the lower temperature.

In commercial carbonization of coal, the heat needed is usually supplied through the walls of the retort. In high-temperature carbonization processes the temperature of the retort walls varies from about 900° C. to about 1,200° C. In such retorts the coal close to the hot walls is quickly heated to the temperature of the walls, and the gaseous products evolved come in contact with the hot walls before they escape; the tar thus produced is truly a product of high-temperature carbonization. However, the coal farther removed from the walls is heated more slowly, the gases are first evolved at low temperatures, and if all of these gases could be condensed without coming in contact with the hot walls (900° C.–1,200° C.) a low-temperature tar would be obtained, but most of these gases do come in contact with the hot walls and are thereby altered. As the carbonization proceeds the temperature toward the centre of the charge increases and slowly approaches that of the walls. The higher temperature causes further decomposition of the coal. The type of products obtained by this later decomposition is different from that first obtained.

The tar recovered from commercial high-temperature carbonization is a mixture of products resulting from the high-temperature decomposition of the coal and of the products formed by the thermal decomposition of the low-temperature and intermediate-temperature tars evolved from the coal.

Two general classes of chambers are used for the production of coal tar: (1) gas retorts, which are relatively small chambers; and (2) by-product coke ovens, which are much larger. Most gas retorts are either horizontal or vertical. Horizontal retorts, the oldest form of gas retorts, vary from about 8 ft. to about 20 ft. in length; they have a shape which is approximately that of a half cylinder with the flat portion forming the floor of the retort. A group of these retorts is built up into banks or "benches"; around the outside of the retorts and through the benches there is a system of flues through which flow the hot gases which thus heat the walls of the retort. Horizontal retorts are heated to about 1,000° C. to 1,100° C. throughout their entire length. The tar liberated from the coal during carbonization in a horizontal retort is in contact with the hot retort walls for a long time before it escapes to the condensing equipment. This prolonged exposure to the high temperature alters a large portion of the tar. Although the walls of horizontal retorts are not much hotter than those of the by-product coke ovens, the ratio of wall surface to coal charge is high and therefore the tars obtained from horizontal retorts have undergone considerable decomposition after their liberation from the coal. Horizontal retort tars are high-temperature tars; they have high specific gravities, are viscous, have only a small amount of tar acids and are high in naphthalene content.

The vertical retorts are the most popular gas retorts in England These retorts are vertical tubes having an elliptical or rectangular cross section. They are usually about 20-25 ft. long and measure 5 ft.-10 ft. by 8-18 in. in cross section. The retorts are grouped in settings. They are heated by means of hot gases passed through flues arranged between individual retorts. Vertical retorts are either of the intermittent or continuous type. In the operation of vertical retorts, coal is charged in at the top and the coke is discharged at the bottom. In the continuous vertical retort, as the coal moves downward it slowly passes through zones of increasing temperatures. The decomposition of the coal starts in the cooler upper regions of the retort and the tars formed there escape from the retort without much change; some of the tar formed in the lower portions of the retort is decomposed by coming in contact with the hot retort walls, but most of this tar passes up through the coal bed and escapes without being thermally decomposed. Hence, the tar which emerges from the vertical retort is a combination of tars, most of which have been subjected to only low-temperature conditions, some that have been exposed to medium-temperatures and a small portion that has been exposed to high-temperatures. Although vertical retorts are considered to be a type of high-temperature carbonizing equipment, the tars produced in these retorts have characteristics intermediate between those of low-temperature and high-temperature tars.

As was mentioned above, the other general type of equipment used to produce tar is the by-product coke oven. More than three-fourths of the tar produced in the United States is by-product coke-oven tar. The modern by-product coke oven is rectangular in shape, about 40 ft. long, 14 ft. high and 16 in. wide. The ovens are built in long rows, called "batteries." The two long walls of the oven are heated by flues in which gas is burned to furnish the heat. These ovens are operated in an intermittent manner. Coal is charged into the ovens through removable doors in the top. After the carbonization is complete, doors at both ends of the oven are opened and the red-hot coke is pushed out by means of a long steel ram. Then another charge of coal is introduced and the process repeated. Some of the gaseous products evolved from the coal during carbonization pass upward along the hot walls of the oven, some of them pass through

the uncoked centre of the coal charge, but some of them pass through the coked and partly coked region of the charge; these gases are largely decomposed as they pass through the heated zones so that a high-temperature tar is formed.

Commercially, coal tar is produced by the carbonization of bituminous coal of the common banded variety. The yield of tar obtained is dependent upon the amount of volatile matter in the coal. When coal is carbonized at high temperatures there seems to be little relationship between the properties of the tar produced and the nature of volatile matter originally present in the coal; the thermal decomposition of the primary tars equalizes their properties.

PROCESSING

The raw tar is processed in various ways to produce a variety of products. The processing is usually not carried out at the plant which produced the tar but is conducted at conveniently located tar processing plants. The processor of coal tar has long been known as a tar distiller. This designation is an appropriate one since distillation is the foundation of the coal-tar industry.

Usually the first step in processing coal tar is to give it a primary distillation to produce a number of fractions or cuts. The number of cuts made and the nature of the cuts vary somewhat at the different plants. In general, at least three cuts are made. These are frequently referred to as light oil, middle oil and heavy oil; the middle oil is also known as tar-acid oil and as crude naphthalene oil; the heavy oil is sometimes called anthracene oil. The material remaining after the removal of the oil distillates is usually either a pitch or a refined road tar base; occasionally, the distillation is carried on until the residue is pitch coke.

The primary distillation is made either in batch stills or in continuous stills. In the United States the commonly used batch still is a horizontal, cylindrical steel vessel; in England it usually is a vertical cylindrical vessel, known as a "pot still." The capacity of the batch stills varies from about 3,000 gal. to about 8,000 gal.

In the continuous distillation of coal tar the most generally used equipment is a tube still, also called a pipe still. Essentially, the tube still consists of a furnace containing a tube several hundred feet long. The tube is either in the form of a spiral or more commonly in straight lengths connected in a continuous manner by means of return bends. The diameter of the tube varies in the different plants but is usually between one inch and five inches.

When tar is processed in a continuous manner in a tube still, it is pumped through the hot tube whereby it is heated to a predetermined temperature. After passing through the tube the hot tar is released either into one tall fractionating column or into several shorter columns which are connected in series. In the fractionating equipment the tar is separated into oil vapours and either a pitch or an intermediate product, as desired. The oil vapours are collected into such cuts as are wanted; the pitch is pumped to storage.

How far the tar is distilled depends upon the products to be manufactured. If the plant is interested primarily in the distillate oils, the tar is distilled to either a hard fuel pitch or even to pitch coke. On the other hand, if the plant is to make specific residual products, such as road tar, briquetting pitch or roofing pitch, the distillation is stopped at an appropriate intermediate point.

In some of the smaller tar distilling plants, the oils obtained by the distillation of coal tar are merely mixed together to make creosote oil. In the larger refineries various chemical compounds are removed from the distillate oils prior to blending them to produce creosote oil.

The coal-tar distillate oils are complex mixtures of hundreds of chemical compounds. Most of these compounds fall into one of three groups: hydrocarbons, acids and bases. Mainly, the hydrocarbons present in coal-tar distillates belong to the aromatic series; typical coal-tar hydrocarbons are benzene (*q.v.*), naphthalene (*q.v.*) and anthracene (*q.v.*). The acidic compounds occurring in coal-tar oils are chiefly phenolic compounds, such as phenol (*see* CARBOLIC ACID OR PHENOL), cresols (*q.v.*), xylenols (dimethylphenols) and naphthols (*see* NAPHTHALENE). Coal-tar bases are cyclic nitrogen compounds; they have the nitrogen either attached to the ring as in aniline (*q.v.*) or forming a member of the ring as in pyridine (*q.v.*); in addition to aniline and pyridine, the picolines (*see* PYRIDINE), quinoline (*q.v.*) and acridine are typical coal-tar bases. Besides hydrocarbons, acids and bases, the coal-tar oils contain: nonacidic oxygen compounds, such as coumarone and diphenylene oxide; nonbasic nitrogen compounds of which carbazole is the most important and organic sulphur compounds; *e.g.*, the mercaptans and thiophenols. Appended to this article is a list of all the compounds that have been identified in coal-tar oils.

Tar Acids.—After the tar has been distilled and the desired cuts obtained, the next processing step in a coal-tar chemical plant is the extraction of the tar acids. These phenolic compounds react with caustic soda to form water-soluble salts. By means of this ability to form water-soluble salts they are separated from the other compounds present in the coal-tar distillates. The process used for the recovery of tar acids is essentially the same in all plants. The light-oil and the middle-oil fractions are washed separately with a dilute aqueous caustic soda solution by thoroughly mixing the two liquids. The mixture is then allowed to settle, whereupon it stratifies into two layers. The lower layer is the caustic soda solution of the tar acids, which solution is called "carbolate"; the upper layer consists of the oils which are not soluble in the caustic soda. The caustic soda solution is separated from the oil layer. Usually, the carbolates from the light-oil fraction and from the middle-oil fraction are combined for further purification; such purification comprises the removal of noncaustic soluble oils that were entrained in the carbolate and is usually accomplished by steaming. The tar acids are liberated or "sprung" from the purified carbolate by treating it with sulphuric acid or with carbon dioxide. The crude mixture of phenols thus obtained is subjected to fractional distillation, usually under vacuum, to obtain a number of products: phenol, orthocresol, cresylic acid and mixed xylenols; cresylic acid is a mixture of tar acids consisting largely of the three cresols (*o*-cresol, *m*-cresol and *p*-cresol) but also containing appreciable amounts of phenol and of the various xylenols.

By special processing, largely in the United States, the cresylic acid and the mixed xylenols are separated into the individual cresols and the individual xylenols. The individual tar acids which are commercially available are shown in italics in the list at the end of this article.

The tar acids present in the heavy-oil fraction are also recovered in some plants. These high-boiling tar acids are seldom fractionally distilled; they are usually used in the form of crude mixtures in the preparation of disinfectants possessing exceptionally high germicidal properties.

Tar Bases.—The more progressive coal-tar refineries recover the basic constituents present in the distillate oils. After the tar acids have been removed, the distillate oils are thoroughly mixed with a dilute aqueous solution of sulphuric acid. The sulphuric acid reacts with the coal-tar bases present to form water-soluble sulphates. Upon standing, the mixture stratifies into two layers: a lower aqueous sulphuric-acid layer containing the coal-tar base sulphates and an upper layer of neutral oil. The base sulphate solution, after being separated from the neutral oil, is purified to remove any entrained neutral oil. Then the bases are sprung by treating the solution with an excess of caustic soda or with a lime slurry. The crude mixture of bases is then subjected to fractional distillation to obtain various individual bases. The bases recovered from the light-oil fraction are pyridine, the picolines, the lutidines and some aniline bases. Frequently, a mixture of light bases is sold as "denaturing pyridine"; such mixtures were added to grain alcohol to make it unfit for human consumption; as the chemical uses for pyridine bases developed, the amount of bases sold as denaturing pyridine became small. From the middle-oil fraction are recovered quinoline, isoquinoline, methylquinolines and acridine.

Beta picoline, gamma picoline and 2,6-lutidine all boil at about 144° C. Because the boiling points of these three constituents of

the light coal tar bases are so close together it is not possible to separate them from each other by ordinary fractional distillation.

In 1941 U.S. chemists found that these three bases could be separated readily from each other by the simple expedient of steam distillation through an efficient fractionating column. This discovery of a means of separating pure beta picoline from coal-tar bases was an important and timely one, for just then there arose a demand for beta picoline in the manufacture of nicotinic acid, the pellagra preventive factor of the vitamin B complex. The simplest and the most direct way of preparing nicotinic acid is by the oxidation of beta picoline. Another commerical method for preparing nicotinic acid involves the oxidation of quinoline to quinolinic acid and then decomposing the quinolinic acid to nicotinic acid.

In a few plants the tar bases present in the heavy-oil fraction are recovered. The mixture of bases thus obtained is a valuable inhibitor in the pickling of steel; it prevents the acid from attacking the steel but does not interfere with the action of the acid in dissolving the scale that is to be removed.

Naphthalene.—After the tar acids and the tar bases have been extracted from the middle oil, the "washed" oil is fractionally distilled to produce a heavy coal-tar solvent naphtha and a naphthalene fraction. The naphthalene fraction, while it is hot, is run into shallow pans; there it cools and crystallizes. The solidified mass is broken into large pieces, which are transferred to a crusher. By being crushed into fairly small pieces the solid chunks are transformed into a thick slurry of crystalline naphthalene suspended in an oil. The naphthalene is separated from the oil either by means of a centrifuge or a hydraulic press. The resulting crude naphthalene is used without further purification for many purposes. For other uses a pure naphthalene is needed. The crude naphthalene is refined by first treating it with either sulphuric acid or metallic sodium, and then distilling it. The distilled liquid naphthalene is usually passed over water-cooled steel rolls whereby it is solidified in thin layers which are then scraped to give "chipped naphthalene"; sometimes the naphthalene is allowed to solidify in pans and then is crushed to give "crystalline naphthalene"; the purest naphthalene is made by sublimation.

Higher Coal-Tar Hydrocarbons.—For the recovery of such higher boiling coal-tar hydrocarbons as acenaphthene (*q.v.*), fluorene, phenanthrene (*q.v.*), anthracene (*q.v.*), pyrene and chrysene, the heavy-oil cut is distilled to obtain fractions rich in the particular compound desired. Such fractions are then chilled to cause the compounds to crystallize. The crystalline substances are separated from the oil and are then purified, usually by recrystallization from solvents.

Light Oil.—The first fraction obtained in the distillation of coal tar is "light oil." It contains the lower boiling constituents of coal tar; *i.e.*, benzene (*q.v.*), toluene (*q.v.*) and the xylenes (*q.v.*). Because of the low boiling point of these compounds only a small portion of them is condensed with the tar; most of them are recovered from the coke-oven gases in a separate step after the tar has been condensed. Because the quantity of light oil recovered from the coke-oven gases is so much greater than that recoverable at the tar distillation plant, it is seldom profitable to refine light oil at a tar refinery. Practically all the processing of light oil is carried out at the tar producing plants.

After the tar and water have been condensed, and usually after the ammonia has been removed, the coke-oven gases are treated to recover the light oil. It is recovered from the gases by scrubbing them with high-boiling coal-tar or petroleum oils, or by absorption on activated carbon. In the oil-washing process the coke-oven gases are passed through a suitable high-boiling tar oil or petroleum oil, which dissolves the light-oil components. The light oil is recovered from the wash oil by steam distillation in a stripping column; the wash oil is used again to scrub more coke-oven gases. In the activated carbon process the coke-oven gases are passed through a bed of activated carbon which absorbs the light oil. The latter is recovered from the carbon by steaming it; the carbon is re-used.

The refining of coal-tar light oils is essentially a combination of fractional distillation and sulphuric-acid washing. A common practice is first to fractionate the light oil to obtain several crude cuts: forerunnings (the most volatile fraction), benzene, toluene, light-solvent naphtha and heavy-solvent naphtha. The further processing of the crude benzene depends upon the use to which it will be put; if it is to be used as a motor fuel, its further processing consists in the addition of an antioxidant; if, however, the benzene is to be used as a chemical or for industrial solvent purposes, it is washed with sulphuric acid and then distilled. The process for refining the crude toluene fraction and the crude light-solvent naphtha fraction is the same as that for the crude benzene.

The crude heavy-solvent naphtha is the main source of the coumarone-indene resins. In order to produce these resins the naphtha is subjected to a special processing. First it is washed with dilute sulphuric acid to remove the bases. Then the resin-forming constituents, the coumarones and the indenes, are polymerized (resinified) by vigorously agitating the washed naphtha with small quantities of concentrated sulphuric acid. The polymerized product is separated from the unreacted oils, dried and polymerized further by heating.

Light Pyridine Bases.—Because of their widely different boiling points, and because of their solubility in water and in oils, the pyridine bases formed by the carbonization of coal are divided between the tar and the gases remaining after the tar has been condensed. In 1937 the demand for pyridine made it desirable to recover more bases from the coke-oven gas. As described above, after the water and the tar have been removed, the remaining gas is passed through dilute sulphuric acid to absorb the ammonia present; the sulphuric acid at the same time absorbs the pyridine bases. The separation of the pyridine bases from the ammonia liquor is accomplished in many ways, usually by neutralization and distillation.

Most of the pyridine, picolines and lutidines of commerce are produced from the light pyridine bases recovered from the coke-oven gases.

Road Tar.—In the manufacture of road tar, the crude tar is distilled to obtain a "road tar base," which is a soft pitch. The road tar base is then cut back or thinned by the addition of a suitable flux oil; the flux oils most commonly used are water-gas tar distillates, coal-tar oils or a light water-gas tar. The extent to which the base is thinned is governed by the particular requirements in each case.

History.—J. J. Becher, a German professor of medicine, is credited with having discovered coal tar sometime prior to 1665. The inability of the British to obtain wood tar from America during the Revolutionary War made them resort to the use of coal tar for treating ships' bottoms, thereby giving the first impetus to the production of coal tar. The introduction of coal-gas lighting in England in 1792 was the next step in the development of a coal-tar industry. The first commercial application of a coal-tar distillate was in 1820 when Charles Mackintosh used coal-tar solvent naphtha to produce a solution of rubber for waterproofing cloth. About 1825, railroad ties were treated with coal-tar distillates to prevent their decay (*see* CREOSOTE OR KREOSOTE). Coal-tar pitch was used for briquetting coal in 1842. When he was a professor at the Royal College of Chemistry in London, A. W. von Hofmann in 1845 discovered benzene in coal-tar distillates. The first coal-tar dye was made in 1856 by William H. Perkin, one of Hofmann's assistants; this was a mauve dye synthesized from aniline, which was made from benzene. In 1868 two German chemists, Carl Graebe and Carl Liebermann, synthesized the dye alizarin from coal-tar anthracene. The discovery of the antiseptic properties of carbolic acid (phenol) by Sir Joseph Lister in 1865 was the next milestone in the development of uses for coal-tar compounds. In 1901 coal tar was first used to surface roads. A new field for coal-tar products was opened in 1907 when Leo Baekeland discovered the bakelite resins; these are made from phenols and formaldehyde. The synthesis of synthetic yarns, such as nylon, from coal-tar products is just another chapter in the history of coal tar.

CONSTITUENTS

The chemical constituents identified in coal tar prior to 1946

are listed below. The compounds are grouped by their chemical nature. In the various groups, they are listed in the order of increasing boiling points. Those hydrocarbons, phenols and bases which are printed in italics were produced commercially in 1946.

Hydrocarbons.—*n*-pentane, isobutylacetylene, pentene-1, cyclopentadiene 41° C., 1,1-dimethylallene, valylene (1,4-pentadiene), 1-methylbutadiene, propylacetylene, methylethylacetylene, *n*-hexane, hexene, 2,3-dimethylbutadiene, diethylacetylene, butylacetylene, *benzene* 80° C., cyclohexane (hexahydrobenzene), cyclohexene (tetrahydrobenzene), dihydrobenzene, methylpropylacetylene (4-hexyne), heptene, *n*-heptane, *toluene* 110.8° C., *n*-octane, ethylbenzene, *m-xylene* 139.3° C., *p-xylene* 138.4° C., 1,2,4-trimethylcyclohexane, *o-xylene* 144° C., styrene, cumene (isopropylbenzene), decane, *n*-propylbenzene, *m*-ethyltoluene, *p*-ethyltoluene, mesitylene (1,3,5-trimethylbenzene), *o*-ethyltoluene, pseudocumene (1,2,4-trimethylbenzene), *dicyclopentadiene* 170° C., hemimellitene (1,2,3-trimethylbenzene), cymene (*p*-methylisopropylbenzene), hydrindene, *indene* 182° C., 1-ethyl-3,4-dimethylbenzene, *n*-undecane, durene (1,2,4,5-tetramethylbenzene), isodurene (1,2,3,5-tetramethylbenzene), 4-methylindene, *tetrahydronaphthalene, naphthalene* 218° C., dimethylindene, *2-methylnaphthalene* 241.1° C., *1-methylnaphthalene* 244.8° C., 2-ethylnaphthalene, 1-ethylnaphthalene, *diphenyl* 255.2° C., 2,6-dimethylnaphthalene, 2,7-dimethylnaphthalene, 1,7-dimethylnaphthalene, 1,6-dimethylnaphthalene, 1,5-dimethylnaphthalene, 2,3-dimethylnaphthalene, 1,2-dimethylnaphthalene, 3-methyldiphenyl, 4-methyldiphenyl, 1,3,7-trimethylnaphthalene, *acenaphthene* 280.7° C., 2,3,5-trimethylnaphthalene, 2,3,6-trimethylnaphthalene, 3,4′-dimethyldiphenyl, 4,4′-dimethyldiphenyl, γ-diphenylenemethane, 4,5-benzondane (1,2-cyclopentanonaphthalene), *fluorene* 298° C., paraffin (octadecane), heneicosane, 2-methylfluorene, 3-methylfluorene, tricosane, tetracosane, pentacosane, docosane, nonadecane, hexacosane, heptacosane, octacosane, *phenanthrene* 340° C., *anthracene* 342.3° C., 3-methylphenanthrene, 4,5-phenanthrylenemethane, 9-methylphenanthrene, 1-methylphenanthrene, 2-phenylnaphthalene, naphthacene, 2-methylanthracene, 2,7-dimethylanthracene, 1,2,3,4-tetrahydrofluoranthene, truxene, *fluoranthene* 384° C., *pyrene* 393° C., retene (8-methyl-2-isopropylphenanthrene), 1,2-benzofluorene (naphthofluorene), 2,3-benzofluorene (isonaphthofluorene), naphtho-2′,3′-1,2-anthracene, 1,2-benzonaphthacene, *chrysene* 448.5° C., triphenylene, crackene, benzerythrene, 1,2-benzanthracene, perylene, 4,5-benzopyrene, 1,2-benzopyrene, 3,4-benzopyrene, picene, 1,12-benzoperylene.

Phenols.—*phenol* 183° C., *o-cresol* 191° C., *p-cresol* 201° C., *m-cresol* 202° C., *1,3,4-xylenol* (2,4-dimethylphenol) 211° C., 1,3,2-xylenol (2,6-dimethylphenol), *1,4,2-xylenol* (2,5-dimethylphenol) 211.3° C., *m-ethylphenol* 219° C., *p-ethylphenol* 218° C., 1,2,3-xylenol (2,3-dimethylphenol), *1,3,5-xylenol* 220° C., *1,2,4-xylenol* (3,4-dimethylphenol) 226° C., pseudocumenol (2,4,5-trimethylphenol), *1,3,5-methylethylphenol* 236° C., isopseudocumenol (2,3,5-trimethylphenol), 7-hydroxycoumarone, 4-hydroxyhydrindene, 3,4,5-trimethylphenol, durenol (2,3,5,6-tetramethylphenol), 5-hydroxyhydrindene, *o-phenylphenol* 275° C., *α-naphthol* 280° C., *β-naphthol* 286° C., *p-phenylphenol* 319° C., tetramethylbiphenol, 2-hydroxydiphenyleneoxide, 2-hydroxyfluorene, hydroxyanthracene, 2-hydroxyphenanthrene (2-phenanthrol).

Nitrogen Bases.—*pyridine* 115° C., *α-picoline* (2-methylpyridine) 129° C., *β-picoline* (3-methylpyridine) 144° C., *2,6-lutidine* (2,6-dimethylpyridine) 143.8° C., *γ-picoline* (4-methylpyridine) 145.4° C., *2,4-lutidine* 157° C., *2,5-lutidine* 156° C., 2,3-lutidine, 3,4-lutidine, 4-ethylpyridine, 2,4,5-trimethylpyridine, 2,3,4-trimethylpyridine, 3,5-lutidine, symmetrical collidine (2,4,6-trimethylpyridine), 2,3,6-trimethylpyridine, *aniline* 184° C., *p-toluidine,* 200.4° C., *o-toluidine* 200.7° C., *m-toluidine* 203.3° C., 2,4-xylidine, 2,5-xylidine, 3,5-xylidine, 2,3-xylidine, 2,3,4,5-tetramethylpyridine, *quinoline* 238° C., *isoquinoline* 243.2° C., *quinaldine* (2-methylquinoline) 247.6° C., 8-methylquinoline, *3-methylisoquinoline* 252.2° C., *1-methylisoquinoline* 255.2° C., 2,8-dimethylquinoline, 7-methylquinoline, 6-methylquinoline, 3-methylquinoline, 5-methylquinoline, *lepidine* (4-methylquinoline) 264.2° C., 5,8-dimethylquinoline, 2,4,6-trimethylquinoline, hydroacridine, *α-naphthylamine* 301° C., *β-naphthylamine* 306° C., *acridine* 346° C., phenanthridine, phenanthridone.

Sulphur Compounds.—ethylmercaptan, dimethylsulphide, carbon disulphide, ammonium sulphide, thiophene, diethylsulphide, 2-methylthiophene, 3-methylthiophene, trimethylthiophene, thiophenol, ammonium thiocyanate, *o*-thiocresol, thionaphthene, methylthionaphthene, diphenylene sulphide, dibenzothionaphthene.

Nonphenolic Oxygen Compounds.—acetone, ethyl alcohol, methylethylketone, acetic acid, propionic acid, coumarone, 6-methylcoumarone, 3- or 5-methylcoumarone, 4-methylcoumarone, acetophenone, 3,6-dimethylcoumarone, 4,5-dimethylcoumarone, 4,6-dimethylcoumarone, benzoic acid, *α*-naphthofurane, *β*-naphthofurane, *diphenylene oxide,* 1-methyldiphenyleneoxide, 2-methyldiphenyleneoxide, 2,3,5,6-dibenzocoumarone, 1,9-benzoxanthene.

Nonbasic Nitrogen Compounds.—methylisocyanide, *acetonitrile* (methyl cyanide), pyrrole, benzonitrile, indole, 3-methylindole (skatole), 7-methylindole, 4-methylindole, 5-methylindole, 2-methylindole, 1-naphthonitrile (1-cyanonaphthalene), 2-naphthonitrile, *carbazole,* 2-methylcarbazole, 3-methylcarbazole, 2,3-benzocarbazole.

See National Research Council, H. H. Lowry, Chairman, *The Chemistry of Coal Utilization,* 2 vol. (1945). (F. E. Cl.)

COAL-TAR DYESTUFFS: *see* DYES, SYNTHETIC.

COALVILLE, a town in northwest Leicestershire, England, 112 mi. N.N.W. from London by the London Midland Region railway route. Pop. of urban district (est. 1938) 24,150. Area 10 sq.mi. This is a town of modern growth, a centre of the coal-mining district of south Leicestershire. There are also elastic web factories, iron foundries and brickworks.

A mile north of Coalville is Whitwick, with remains of a Norman castle, while to the north again are remains of the nunnery of Gracedieu, founded in 1240.

COAST, the edge of the land in contact with the sea. The term (from Lat. *costa,* a rib, side) is sometimes applied to the bank of a lake or wide river, and sometimes to a coastal zone (*cf.* Gold Coast, Coromandel Coast). If the coast line runs parallel to a mountain range, such as near the central Andes, it has usually a more regular form than when, as in the *rias* coast of southwest Ireland, it enters between the crustal folds. A recently elevated coast is usually regular, while a recently depressed coast shows the irregularities which were present upon the surface before submergence. Waves and sea currents are the chief agents in coast sculpture. A coast of homogeneous rock exposed to steady erosion will present a regular outline, but if exposed to differential action it will be most embayed where the action is greatest. A coast consisting of rocks of unequal hardness will be marked, when the wave and current action remains similar throughout, by headlands, "stacks" and "needles" of hard rocks, and bays or gulfs of softer or more loosely aggregated rocks, *e.g.,* the southern shore lines of the Isle of Wight and of southwestern Wales. Subsequently the coast becomes "mature" and its outline undergoes little change as it gains on the land, for the hard rock being now more exposed is worn away faster than the softer rock which lies protected in the bays and re-entrants.

COASTAL HIGHWAY: *see* ATLANTIC COASTAL HIGHWAY.

COAST DEFENSE. One of the primary missions of a military establishment is the protection of its country's coast against attack and invasion by an enemy power in time of war. During World War II, the wide use of military aircraft and the introduction of radar and other electrical detection devices, the experimental use of guided missiles and the employment of carrier-based planes and other innovations changed the concepts of coast defense radically. Postwar research and development produced planes flying at supersonic speeds and capable of girdling the earth. The construction and use of guided missiles and rockets reached a high degree of perfection. The destructive possibilities of the atom bomb and the hydrogen bomb advanced beyond the point of being an inventor's dream. All of these, plus hundreds of other scientific developments with high potentials as instruments of warfare, definitely pointed to the necessity of continuously changing ideas to secure the integrity of a nation's territory against enemy action in time of war.

While the concepts had changed, however, the objectives of coast defense still went back to the earliest days when naval vessels were first used to carry an invading field force to the home shores of an adversary. Broadly stated, the first objective is to prevent a hostile sea-borne force from landing on the coast or an enemy air force from crossing the coast line for the purpose of interior penetration. The second objective is to repel a successful landing quickly before an enemy can establish a beachhead and push inland, or to turn back an air-borne assault before it can reach a vital target. The third objective is to maintain safe ports and harbours from which a nation's fleet can operate and enjoy protection against sneak attacks or harassing action by enemy naval forces.

The best way to accomplish any and all of these objectives is, of course, to nip an invasion in the bud at the enemy's staging area before his forces can get launched or, by maintaining the initiative in defense and thus destroying his own defenses, crippling his industry and resources and shattering morale, prevent the possibility of invasion plans or preparations. This is the implementation of the old military axiom that the best defense is a strong offense.

In the early days of warfare, protection against invasion was a relatively elementary problem. Known harbours and navigable inland streams were almost certain to be the approach points of a hostile sea-borne force. Consequently, in time of peace, it was possible to make preparations against a future emergency. These consisted of building fortifications at strategic locations and having channel chains and other types of movable barriers ready for employment in time of attack or threat of attack.

Until comparatively modern times this was the fundamental method of coastal defense. The mechanical propulsion of ships producing ever-increasing speed and manoeuvrability, and the widening ranges of guns, called for changes in techniques and equipment but the concepts of defense changed but little.

Nations most removed by the seas from potential enemies were the most secure from hostile attack. In this respect, the United States was particularly fortunate. Enjoying practically continuous amity with its neighbour to the north and only occasional hostility with its neighbour to the south, the only serious threat to the integrity of its soil could normally come from across the Atlantic or the Pacific oceans. It was true until the advent of World War II that the sea provided the best U.S. defense against enemy forays. The United States, however, had been successfully invaded from the sea during its two earliest wars, and methods to forfend such proven possibilities had been under consideration practically since the birth of the nation.

In 1793, George Washington advised congress that the vulnerable portion of the U.S. coast line should be fortified. His advice went unheeded for a year but in 1794, Gen. Henry Knox, who had been Washington's chief of artillery, drew up plans for harbour defense works for which a small amount of money had been provided. These works never got much beyond the planning stage, because of lack of funds, until after the War of 1812 when the reverses suffered at the hands of a small force of regular British troops convinced the U.S. people of the necessity for some permanent opposition to hostile landings. In 1816 construction of defensive works was begun and during the next 45 years most of the important harbours on the Atlantic and Gulf coasts were protected by a series of closed masonry forts. During the American Civil War many of these forts gave excellent accounts of themselves and capitulated to greatly superior forces only after extensive siege operations.

Subsequent to the Civil War coast defense languished for 20 years, but in 1886 the subject received renewed impetus and the succeeding two decades witnessed the construction, at all important harbours in the continental United States, of defensive works designed solely to repulse attack by naval gunfire. These works were very vulnerable to assault from the land side and this fact, coupled with the implication inherent in the existence of long stretches of undefended coast between the fortifications, led students of national defense to consider, apparently for the first time in half a century, coast defense as distinguished from purely harbour defense.

The result of this consideration was the adoption of a system of defense which was largely negative and which placed upon coast artillery troops not only the responsibility for serving their guns but also that of acting as infantry in their own support in the event that enemy troops succeeded in effecting a landing in the vicinity of the batteries. Lack of sufficient mobile troops to provide the supporting elements was responsible for this makeshift arrangement, which prevailed for nearly ten years; in fact, until the entry of the United States into World War I in 1917.

At that time the U.S. harbour defenses mounted both guns and mortars of large, medium and small calibre, together with ammunition and fire control necessary for their effective tactical employment against naval vessels. In addition, a thoroughly efficient system of submarine mines had been developed and was ready for installation. Harbours in the Panama Canal Zone, Hawaiian territory and the Philippine Islands, as well as those in the continental United States, were provided with their quota of permanent fortifications.

Calibres of weapons ranged from 3 in. up to and including 16 in.—sufficient in power and range to combat effectively any naval armament afloat. Weapons were more or less dispersed with connecting control and supply lines concealed and protected. Prior to the use of aeroplanes for reconnaissance and fire direction many U.S. guns were mounted on disappearing carriages located behind parapets, so that the guns and their accessories were invisible from the sea. Modern coast defense installations up to and including the World War II period relied on camouflage and dispersion as well as limited mobility secured by mounting cannon on railway carriages which enabled rapid change of positions for the big coast artillery weapons.

Subsequent to World War I, two schools of thought grew up on the subject of the proper type of weapon for harbour defense. One maintained that fixed defenses were obsolete, or at least obsolescent, and that all future defensive installations should be railway guns which could be moved from point to point to meet naval threats. Their opponents, while agreeing that railway artillery had many advantages, particularly in specific localities such as the Panama Canal Zone, maintained that it was not the whole answer to the problem of fortification of harbours. They reasoned that naval forces could move more rapidly than heavy railway artillery and that it was necessary to have heavy artillery available and ready to function at strategic points before the arrival of a hostile fleet. A compromise view eventually prevailed. Both types of weapons were in use at the time of the U.S. entry into World War II.

The European conflicts also taught the U.S. that a proper solution of the problem of coast defense required more than mere resistance by harbour defense artillery to naval bombardment. Coast defense concerns all arms and demands employment of all branches of the army, organized and trained to function as a team. This conception led to the adoption of what is known as a "positive system of coast defense," in which not only all branches of the army participate but also selected elements of the navy and the air force.

Coast defenses may be attacked from the land, sea or air and such attacks may be separate or co-ordinate. The likelihood of separate sea or land attack against coast defenses is remote unless the attacker has control of local sea areas. But separate air attacks, combinations of land and air attacks or sea and air attacks are certain, just as the combination of all three basic forms is inevitable. Coast defenses have to provide resistance to all of these.

Fleets cannot be relied upon for defensive missions; they should never be tied to the defense of any harbour or section of coast line no matter how important; their proper function is always the offensive, to seek out and destroy the enemy on the sea or in his home bases. The same logic applies to air forces. Therefore, the burden of coast defense must be borne by land forces, which, however, must have both naval and air support.

In light of the modern weapons and machines of war, a nation with expansive coastal areas, such as the United States, is po-

tentially vulnerable at practically any point. Defenders no longer can expect attack at a comparatively few predetermined points of opportunity and prepare strong defenses for their protection. Remote beaches can be assaulted by sea-borne forces. And in the air there are no limitations of a geographical nature that an enemy need surmount. For this reason most of the fixed coast defense forts and batteries were abandoned as structures in a modern nation's defensive system, probably on the premise that they might prove as ineffective as was the Maginot line on the inland border of France or the "impregnable" defenses on Corregidor and Fort Drum in Manila bay during World War II.

To a great extent the few fixed coast artillery defenses remaining after World War II followed a general pattern. Coast defense cannon were ordinarily emplaced in pairs, especially those of 12 in. or larger calibre, although in some instances they might be mounted singly or in groups of from four to eight. Each pair or group, together with the necessary fire control and fire direction facilities, ammunition supply installation and other accessories, was usually referred to as a "battery." This same term was used to designate the men operating the guns. The ammunition storage, fire control stations and battery commanders' stations were ordinarily located so as to take advantage of such natural protection as the ground near the battery afforded, consistent with the ability to perform their battle functions efficiently. Usually electric power was provided for working the guns, handling heavy ammunition and, of course, for communications.

In order to deliver accurate and rapid fire at a moving target such as a battleship the shore battery determines firing data by a method of finding the various positions of the target at stated intervals of a time sequence, say every minute for a period of five minutes, then predicting from this known data where the ship will be at the end of another interval of time, say the end of the sixth minute. Thus, being able to predict the probable future course of the target, and its probable location at a selected future instant, it is possible to relate such prediction to the position of the gun, point the gun ahead of the ship and fire the gun so that the ship and projectile will arrive at the same point simultaneously. This procedure is known as position-finding, and the most common development of it is the horizontal base system, which requires two observation posts located at the end of a carefully measured line several thousands of yards in length, called a base line. These stations are equipped with powerful optical instruments with which simultaneous observations are made on the target.

The data thus obtained are telephoned to a central station called a plotting room, where they are processed, either graphically or automatically, so as to result in determination of the distance and direction of the target from the guns. These results are then set on appropriate scales on the guns or carriages, the guns are pointed accordingly and are fired, usually electrically, at the proper instant.

Obviously this system and its variations, such as the vertical base system in which the height of one observing instrument above sea level replaces the horizontal base of the parent system, depend upon ability to see the target from shore. In the case of long-range fire, where the target is invisible from shore, the shooting must be directed from aircraft. Such fire will naturally be less accurate than that directed by shore stations and will involve radio communication between aeroplane and shore stations.

Conversely, ships' fire under similar conditions of range will be directed by aircraft. It is evident that control of the air is indispensable to the delivery of accurate fire by either side under these circumstances.

The necessity for control of the air certainly leads to extensive air activity precedent to naval action against coast defense works. In fact, it may be doubted if such actions can be attempted unless air superiority can be gained. Hence, the closest co-operation and mutual support between coast defense forces and defensive air forces becomes of paramount importance. Also the provision of anti-aircraft defense in and about fortified harbours becomes essential. While air supremacy is a prerequisite of a successful attack on fortified harbours, it is equally essential when a landing is to be attempted on open beaches against well-organized resistance. In such operations the attacker is under the necessity of disembarking his troops from transports into small boats at a great distance from shore and these troops will need the support of well-directed naval gunfire from the time of such debarkation until they have established themselves on shore. During this time they are most vulnerable to fire of all descriptions—infantry, artillery and aircraft.

All these considerations gave rise to the typical coastal defense conception comprising the following elements given in the order of their appearance from front to rear: (1) distant naval and air reconnaissance or radar to detect enemy preparation for an overseas movement; (2) naval and air action to counter such efforts before they get under way; (3) naval and air action to meet such an effort at sea and defeat it there if the enemy succeeds in launching it; (4) naval and air offshore patrolling and scouting and other methods of detection to give early warning of the approach of hostile forces; (5) naval and air inshore patrolling to cover naval mine fields or other obstructions; (6) army controlled mines and accessories and fixed underwater obstacles and listening devices; (7) mobile coast defense artillery, in combination with anti-aircraft guns; with both fire control and searchlights supplemented by aircraft support, warning service and beach defense; (8) mobile army forces of all arms strategically located and capable of rapid movement and co-ordinated action.

This setup when composed of troops well-organized, well-trained, well-equipped, well-supplied and competently led can make a hostile landing effort so expensive to the attacker as to deter him from the attempt except as a last resort or unless he has such overwhelming superiority in one or more elements of combat as to convince him that his effort will succeed.

No matter what the doctrines of warfare and the concepts of defense might develop, the elements of surprise, feint and harassment—to as great an extent as possible—would be used by invading forces. Taking the place of casemates and cannons after World War II were defense devices to guard the portal entrances of the coasts against the type of attack appearing to be most likely. There is always the possibility of a sneak attack by hostile submarines such as resulted in the sinking of the British battleship "Royal Oak" inside Scapa flow by the German submarine skipper Lieut. Comdr. Guenther Prien in Oct. 1939. Other objectives of sneak attacks might be to plant mines to harass shipping, deliver atomic bombs to destroy harbours or to gather intelligence.

Electric mines controlled from shore locations and antisubmarine nets are two of the most effective types of coast defenses against such sneak attacks. These, of course, are complemented by sea and air patrols, radar and other types of electrical and listening devices and shore-based searchlight batteries.

On a large scale, the most likely invasion that a nation must prepare to repel would be air-borne in its initial phases. Regardless of the tremendous destructive power of an atomic bomb and the devastating effects of all types of bombs and guided missiles on the morale and the productive resources of a nation, it was widely agreed following World War II that a war could be won only after ground forces had entrenched themselves in hostile territory for the purpose of strangling the economy and the political authority of the enemy. For this purpose a sea invasion with air cover to set up a beachhead is within the realm of possibility, but for an adequately defended nation with sufficient military intelligence to provide for its defense with well-equipped mobile forces, such an operation might be extremely costly to the invader in personnel, ships, planes and supplies. Coast defense strategy, therefore, must take cognizance of a more logical type of attack.

In the era of long-distance flying, an air armada of transport planes could take off from secured bases, or, on a lesser basis, from sea-borne carriers and strike for an invasion point of its own choosing and at a time of its own selection.

Such an attack would demand air superiority in the invasion area, since unarmed transport planes, filled with paratroopers, need as much protection in the air element as transports and supply ships need on the seas. Prior to an air-borne invasion it would be necessary for an invader to keep the air lanes free of the planes employed in defending the coast. Target points of primary

importance during the "softening up," or preinvasion, period would be airfields, supply depots and troop concentrations in the broad area of the contemplated invasion—with just enough feinting in other areas to confuse the coast defenders. Roads and railroads would come in for their share of strafing and destruction, as would known fixed and mobile anti-aircraft defenses. Such obvious targets, therefore, would require large-scale protection by both ground and air forces. The fixed ground forces defending the coastal approach lanes of an invader would need the support of reinforcements equipped with sufficient anti-aircraft artillery and other mobile equipment to repel the preinvasion attacks. These attacks would undoubtedly be scattered over a depth well beyond the usual conception of a coast line. Protection against guided missiles, jet projectiles and robot (unmanned) planes would also be figured in the defensive strategy. The majority of these new defensive weapons and strategies remained closely guarded secrets after World War II.

It was revealed, however, that a radar network spanning the continent near the border between the United States and Canada was in operation in the mid-1950s, and engineering work on a line across mid-Canada had been undertaken.

To give the earliest possible warning of the approach of hostile aircraft, it was planned to establish radar stations along a line across the most northerly practicable part of the continent of North America.

With such varied possibilities of hostile invasion confronting the defenders of a coast line in time of war and with the coast becoming a deep, undetermined segment of the country rather than a narrow perimeter washed by the sea, innumerable defense plans must be worked out in advance for the selection of the high command when the nature of the invaders' attack begins to take actual shape.

Worked out in time of peace, these plans take into account every conceivable possibility that imagination and experience can inject into a theoretical situation. From time to time they are studied and revised and brought up-to-date to conform to new developments and the estimates of contemporary intelligence. In the event of an actual invasion, however, much of the strategy of the defenders would have to be worked out during the heat of the engagement. In general, defense depends upon mobility and strength. Particular emphasis would be placed on anti-aircraft artillery complemented by a close-knit coastal ring of electrical detecting devices to prevent a surprise attack. Since the units of an air-borne invasion force can be assembled at any number of widely separated bases for prearranged massing in the air on D-day, military intelligence gleaned from observation and through other available sources cannot be relied upon to guard completely against surprise.

Air-borne troops alone could not be depended upon to invade a nation and hold their landing indefinitely against the onslaughts of the defenders, despite the fact that such troops might be accompanied by air-transported artillery, tanks, vehicles and other equipment.

Air-borne insufficiency to complete an over-all mission presents still another coast defense problem. Hostile air-borne troops would most likely be dropped well behind the actual coast line to battle back against the defender's coast-dispersed troops. These invaders would be followed by sea-borne reinforcements who would attempt landings on the coast. These elements would constitute the major portion of the invading army; its mission would be to secure a beachhead and to fight through to the air-borne elements in the rear of the defending forces. To prevent the success of the sea-borne phase of invasion there would remain the obvious necessity of keeping a strong mobile force in readiness along the coast line to repel the anticipated landing assaults under a strong cover of air support.

Equally important to military defense in wartime is the necessity for dispersal of manufacturing facilities, stock piles and other logistical assets. Much of these would be forced to go underground and as far inland as would be economically possible. Likewise, the responsibility of all citizens to play a part in the defense of their homeland against invasion would be tremendously increased.

The problem of coast defense was no longer one for the military alone. Participation in aircraft spotting and warning, fire fighting, first aid and evacuating services would be required in a total war.

Thus Great Britain and the United States re-established warning systems after World War II and took various steps to build up an effective civil defense program. The British Royal Observer corps was reorganized in 1946, and the United States established the Ground Observer corps, a civilian component of the air force.

By the end of 1954 about 375,000 civilian volunteers, who served without pay, were enrolled by U.S. state and local civil defense directors to supplement the radar coverage.

Under the Federal Civil Defense act of 1950, approved Jan. 12, 1951, the United States established the Federal Civil Defense administration to provide co-ordination and guidance to the states and their political subdivisions, where the primary responsibility for the operation of civil defense was vested. (*See* also OBSERVER CORPS IN AIR DEFENSE.)

COAST GUARD, a force, usually naval in character, maintained in some countries for the suppression of smuggling or for affording assistance to vessels in distress or wrecked and for other coastal duties such as signalling.

Britain's coast guard, which is mainly concerned with lifesaving, had its origin in an organization formed under the customs to prevent smuggling at the end of the Napoleonic Wars. Under the Coast Guard act of 1856 the control of this organization was transferred to the admiralty in order to make better provision for coastal defense; to provide a reserve for the navy in case of war; and to protect the revenue. This act made no reference to lifesaving.

In the first half of the 19th century a number of private lifesaving companies were formed on the coast. In 1854, the board of trade became responsible for these companies and gradually provided further lifesaving apparatus companies all around the coast. The coast guard service helped to train these lifesaving companies. From 1910 onward they also provided a few lookout huts at danger points not covered by the existing coast guard organization. In 1923 the coast guard was transferred to the board of trade, and lifesaving and coast watching were combined under one head.

In 1938 the ministry of shipping took over the functions and powers of the mercantile marine department of the board of trade, including the administration of H.M. coast guard, and these functions and powers were later transferred to the ministry of war transport (later successively the ministry of transport and the ministry of transport and civil aviation).

The present organization exists primarily to help save lives in cases of shipwreck and distress at sea. For this purpose the coast guard keeps a lookout for vessels or aircraft in distress or danger, and gives assistance directly by means of the lifesaving appliances provided and indirectly by informing the lifeboat, air traffic control and other authorities in a position to help.

The coast-watching system is based on the maintenance of visual watch from some 314 lookout huts, usually sited on headlands or other vantage points overlooking dangerous waters. The distance between huts is about five miles where the small ship traffic is heavy and runs close to the coast, but is greater elsewhere. The normal type of watch is a bad weather watch, and (apart from occasional scanning of the coast by day) constant watch is only kept at points where there is a large volume of small coastal and fishing-boat traffic and the navigational hazards are such that immediate action is necessary to save lives if a casualty should occur even in fine weather.

A night watch is kept in fine weather at a sufficient number of

stations to ensure that watch is set at all the other stations affected on the approach of bad weather.

In addition to this visual watch, a constant listening watch on the marine distress waves is kept by the ten coast radio stations of the general post office around the coasts of Great Britain. Any distress messages received by these radio stations are immediately passed by telephone to the nearest coast guard station, which in turn initiates all rescue measures.

The staff at coast guard stations are usually drawn from pensioners of the royal navy or men from the merchant navy with equivalent sea service. The lifesaving appliances are worked by teams of local men formed into companies of the Coast Life Saving corps. This corps, which has a voluntary basis, was founded in 1932 to assist the regular coast guard. In addition to forming the lifesaving companies, the members of the corps keep visual watch in bad weather from auxiliary stations and also help in relief work at regular stations. (J. H. Ly.)

UNITED STATES

Origin.—The United States coast guard traces its origin to the ten small armed boats authorized by the first congress on Aug. 4, 1790, to guard the nation's coast against smuggling from the sea and enforce custom laws. Known first as the revenue marine and later as the revenue cutter service, it became officially the U.S. coast guard when it was combined with the lifesaving service on Jan. 28, 1915. The lighthouse service, which had come under federal control on Aug. 7, 1789, was consolidated with the coast guard in 1939, and the bureau of marine inspection and navigation was transferred from the department of commerce to the coast guard in 1942. Thus the principal maritime agencies were organized as one united service.

Duties and Organization.—The functions of the U.S. coast guard embrace, in general terms, maritime law enforcement, saving and protecting life and property, providing navigational aids to maritime commerce and to transoceanic air commerce, promoting the efficiency and safety of the U.S. merchant marine and readiness for military operations.

The primary purpose of most of these duties is to prevent avoidable loss of life and property resulting from illegal or unsafe activities. In actual practice, however, the maintenance of safety and order in maritime navigation is not limited to the strict enforcement of laws, but also encompasses a continuing program of education among ship operators and boatmen and the enlistment of their co-operation and self-regulation in the prevention of marine disasters.

The organic act of 1915, as revised, provided that the coast guard ". . . shall be a military service and a branch of the armed forces of the United States at all times." It further provided that "the Coast Guard shall be a service in the Treasury Department, except when operating as a service in the Navy." Such service in the navy takes place upon the declaration of war or when the president directs.

The coast guard's peacetime organization, regulations, training and customs parallel those of the navy insofar as operations will permit. Personnel receive the same pay and allowances as prescribed for corresponding ranks, grades and ratings in the navy, and uniforms are identical except for the coast guard's shield insignia.

The coast guard, as the principal maritime law enforcement agency of the federal government, enforces or assists in the enforcement of all applicable federal laws upon the high seas and waters subject to the jurisdiction of the United States. It administers laws and promulgates and enforces regulations for the promotion and safety of life and property, covering all matters not specifically delegated by law to some other executive department. Among the more important are enforcement of the navigation and inspection laws and assistance in the enforcement of the Oil Pollution act, and of laws relating to internal revenue, customs, immigration, neutrality, and conservation and protection of fisheries and wildlife. It enforces rules governing the security of ports, anchorage and movement of vessels in territorial waters.

The coast guard had developed and operated in the mid-1950s more than 38,000 aids to maritime navigation, such as lighthouses, lightships, lights, radio beacons, radio-direction-finder stations, buoys and unlighted beacons, as required to serve the needs of commerce and the armed forces.

In the promotion of safety of life and property, coast guard duties include the inspection of vessels and their equipment; investigation of marine casualties; regulation of the outfitting and operation of motorboats, of the transportation of dangerous cargoes of vessels, and of the construction and repair of vessels; enforcement of manning, citizenship, mustering, drilling-crew and load-line requirements; protection of merchant seamen; and licensing of officers, pilots, seamen and motorboat operators.

The coast guard maintains an established organization of inshore and offshore rescue surface vessels, aircraft, lifeboat stations and radio stations, together with rescue co-ordination centres in each district. It extends medical aid to crews of U.S. vessels, transports shipwrecked and destitute persons in Alaska and elsewhere and engages in flood relief work. It operates ocean stations in both the North Atlantic and North Pacific to provide search and rescue, communication and air navigation facilities in areas traversed by U.S. aircraft. Another duty is to conduct the annual International Ice patrol in the North Atlantic to protect shipping from icebergs.

The administrative head of the coast guard is the commandant, with headquarters in Washington, D.C. In most instances activities were directed in the mid-1950s by 12 district commanders and performed by individual operating units such as ships, aircraft and marine inspection offices.

History.—The early revenue marine soon found itself charged with many other duties in addition to the enforcement of customs laws. These activities included distinguished service in every conflict in which the United States engaged, with the exception only of the war with Tripoli. A revenue cutter, "Harriet Lane," is credited with firing the first shot in the Civil War, on the eve of the bombardment of Fort Sumter, S.C. The cutter fleet of 28 vessels helped enforce the blockade and lent support to the army and navy striking into the south.

On April 6, 1917, when war was declared by the United States on Germany, the navy was augmented by 15 cruising cutters, about 200 officers, and 5,000 warrant officers and enlisted men of the coast guard. They were entrusted with the hunting of submarines and raiders and with guarding the transport of troops. A squadron of coast guard cutters, based at Gibraltar, performed escort duty between that port and the British Isles. While on this duty the cutter "Tampa" disappeared on the night of Sept. 26, 1918, with a loss of 111 coastguardmen and four navy men. It is believed that the "Tampa" was torpedoed. In proportion to its strength, the coast guard suffered the highest losses of any of the armed services in World War I.

The coast guard reached its peak strength in World War II. It had 802 vessels (more than 65 ft.) of its own and, in addition, manned 351 navy and 288 army craft. By June 30, 1945, its personnel numbered 171,168. Of these, 572 were killed in action. Coast guard surface craft destroyed 11 U-boats and aircraft sank another. More than 4,000 survivors of torpedoings and other enemy action were rescued from the Atlantic and Mediterranean. Another spectacular war duty was the manning of assault craft in landings in North Africa, Europe and in the Pacific. The coast guard's years of experience in operating small boats through the surf made it the logical organization to train and supply crews for landing craft from the smallest barges to the giant LST's (landing ship tanks). Coast guard crews also served on many of the large assault transports which carried the barges and troops within striking distance of the beachheads.

On D-day in Normandy 83-ft. coast guard cutters were given special lifesaving duties. Under fire from German guns, they rescued 1,468 men from sunken landing barges. On June 30, 1954, military personnel consisted of 3,177 commissioned officers, 452 commissioned warrant officers, 343 cadets, 454 warrant officers and 30,065 enlisted men. Larger ships in commission included 195 cutters and buoy tenders, 63 patrol boats, 36 light-

ships and 137 aircraft. The motto of the coast guard is *Semper Paratus* (Always Prepared). (*See* also UNITED STATES COAST GUARD ACADEMY.) (A. C. RD.)

COASTING, usually called tobogganing (*q.v.*) in Europe, the sport of sliding down snow or ice-covered hills or artificial inclines upon hand sleds, or sledges, provided with runners shod with iron or steel. It is uncertain whether the first American sleds were copied from the Indian toboggans, but no sled without runners was known in the United States before 1870, except to the woodsmen of the Canadian border. American laws have greatly restricted and in most places prohibited the practice, once common, of coasting on the highways, and the sport is mainly confined to open hills and artificial inclines or chutes. Two forms of hand sled are usual in America, the original "clipper" type, built low, with long, pointed sides, formerly shod with iron but since 1850 with round steel rods for runners; and the light, short "girls' sled," with high skeleton sides, usually flat shod. There is also the "double runner," or "bobsled," formed of two clipper sleds joined by a board and steered by ropes, a wheel or cross-bar, and seating from four to ten persons.

In the U.S., coasting enjoyed considerable popularity into the early decades of the 20th century. After 1932 it ceased to be rated an important winter sport at resorts in the Adirondacks of upper New York state and New England, where the emphasis is all on skiing. In the eastern cities of Canada, however, coasting is still a popular pastime. The chute at Mt. Royal, Montreal, consists of five tracks side by side, separated by ice. Dufferin Terrace, Que., has a three-track chute.

In Scandinavia several kinds of sled are common, but that of the fishermen, by means of which they transport their catch over the frozen fjords, is the one used in coasting, a sport especially popular in the neighbourhood of Oslo, where there are courses nearly three miles in length. This sled is from four to six feet long, with skeleton sides about seven inches high, and generally holds three persons. It is steered by two long sticks trailing behind. On the ice the fisherman propels his sled by means of two short picks. The general Norwegian name for sledge is *skijälker*, the primitive form being a kind of toboggan provided with broad wooden runners resembling the ski (*q.v.*). In northern Sweden and Finland the commonest form of single sleds is the *Sparkstottinger*, built high at the back, the coaster standing up and steering by means of two handles projecting from the sides.

Coasting in its highest development may be seen in Switzerland, at the fashionable winter resorts of the Engadine, where it is called tobogganing. The first regular races there were organized by John Addington Symonds, who instituted an annual contest for a challenge cup, open to all comers, over the steep post road from Davos to Klosters, the finest natural coast in Switzerland, the sled used being the primitive native *Schlittli* or *Handschlitten*, a miniature copy of the ancient horse sledge.

The construction of great artificial runs followed, the most famous being the "Cresta" at St. Moritz, begun in 1884, which is about 1,320 yd. in length, its dangerous curves banked up. The famous run has an electrical timing apparatus. The record time for the descent is 53.7 sec. made in 1911, an average speed of 47 mi. per hour. The total drop from start to finish is 514 ft., the average gradient 1 in 7.7. On this the annual Grand National championship is contested, the winner's time being the shortest aggregate of three heats. In 1885 and the following year the native *Schlittli* remained in use, the rider sitting upright facing the goal, and steering either with the heels or with short picks. In 1887 the first American clipper sled was introduced by L. P. Child, who easily won the championship for that year on it. The sled used by the contestants is a development of the American type, built of steel and skeleton in form. With it a speed of more than 80 mi. an hour has been attained. The coaster lies flat upon it and steers with his feet, shod with spiked shoes, to render braking easier, and helped with the gloved hands. This is called the *ventre-à-terre* position. The "double runner" has also been introduced into Switzerland under the name of "bobsleigh."

Olympic Competition.—Bobsled racing first figured in the Olympic winter games at Chamonix in 1924, when Switzerland won, Great Britain was second and Belgium third. There are usually races for the two-man and four-man sleds, and when the games were held at St. Moritz (1928, 1948) a skeleton event was also included in the program. Each nation may enter three sleds in each event but only two may compete. Races are run on several descents of the track, the results determined by the totals of the times. Electric timing devices are used.

In 1928 and 1932 the U.S. captured first place in all the bobsled events. John Heaton, skeleton winner in 1928, returned to St. Moritz 20 yr. later to take second place in the event, a remarkable achievement. The games of 1932 were held in the U.S. at Lake Placid, where, on Mt. Hoevenberg, is the only bob run in the nation which meets Olympic requirements. This run is 2,350 m. or approximately 1½ mi. long. It has a total of 28 curves, some of which are 22 ft. high. The average drop is 10%, maximum 15%.

In the fourth Olympic winter games at Garmisch-Partenkirchen, Germany, 1936, the four-man bobsled competition was won by Switzerland, but the U.S. again won the two-man event. In 1948 the winning nations were reversed—the Swiss won the two-man, the U.S. the four-man. N. Bibbia of Italy won the skeleton tobogganing medal. Germany, admitted for the first time since World War II, won both bobsled events in 1952. Andreas Ostler drove both the winning sleds.

The four-man bobsleds of latest design weigh close to 500 lb., and speeds exceeding 70 m.p.h. have been obtained.

COAST PROTECTION AND LAND RECLAMATION. Shore lines of oceans, bays and estuaries are subject to both seasonal and long-term changes, under the combined influence of the supply of debris from streams and cliffs and of waves, tidal effects, currents and wind transport. In many localities the seasonal fluctuations take place about a constant position, but there are some reaches of the shore line where the long-term trend is either erosion or accretion. By means of structures or by artificial fill, land area may be reclaimed or erosion retarded. The construction and maintenance of such projects involve difficulties and uncertainties as to both cost and design, and the value of the land or of the improvements on it must usually be high to justify protective works.

Causes of Coastal Changes.—The breaking of waves is the principal cause of erosion or accretion of shore lines exposed to the sea. In protected bays and estuaries and along exposed coasts adjacent to estuaries and tidal entrances, both waves and tidal currents are effective in causing changes. Transportation of sand by wind and the formation of sand dunes sometimes plays a part occasionally a major one.

Waves are generated by winds blowing over the surface of the ocean. The height of a wave, measured from trough to crest, and its length depend upon the velocity of the wind, on its duration and on the fetch or the length of ocean area exposed to the wind. For each wind velocity there is a minimum duration which must be equalled or exceeded if the waves are to attain their full development, and this minimum duration increases with wind velocity. Similarly, there is a minimum fetch necessary for full wave development under each wind velocity. Trains of wind-generated waves are variable as to height, period and direction in the generating area, but each wave condition may be characterized by a height and a period which are related quantitatively to the velocity, duration and fetch of the generating wind. Winds over the open ocean follow curved paths but the waves generated by them move out tangentially and apparently become longer and lower as they advance from the generating area to the shore.

The quantitative relationship between generating winds and generated waves, developed by H. U. Sverdrup and W. Munk has great utility both in forecasting the waves to be expected from a current weather situation and in "hindcasting" from historical weather charts the general wave "climate" of a shore line. This technique has been applied widely. Information regarding wave characteristics is also obtained at certain localities from wave recorders which obtain a continuous record of height and period.

FIG. 1.—SEA WALL AT GALVESTON, TEX.

When waves move into shoal water their velocity decreases and, if they approach the shore line obliquely, the end of the crest nearer shore moves at a lower velocity and the wave turns. This phenomenon is known as refraction. Long waves "feel the bottom" in deeper water than do short ones. The tendency is for the wave crests to swing around so as to become parallel to the bottom contours. Waves transport energy in the direction of their motion, the amount of energy per foot of wave crest being proportional to the wave length and to the square of the height. This energy is carried forward perpendicular to the wave crest. Whenever refraction elongates the wave crest, the energy must be distributed over this greater length and the height must decrease. Conversely, when refraction causes the crest length to decrease, as in the convergence at a headland, the wave height is increased.

Another effect of shoaling water, and of the related decrease in wave velocity, is that the wave length must decrease and the height from trough to crest must increase to maintain constant energy per wave. This process ultimately results in the wave height becoming too great for the depth of water and the wave breaks, dissipating nearly all of the wave energy in the turbulence of the breaker and in the foaming crest which proceeds shoreward with steadily diminishing height. If the wave crest in deep water approached the shore line obliquely, the breaking wave, after refraction, will also make an angle with the shore. The obliquity of the breaker depends both upon the original deepwater angle and wave steepness. The depth of water in which waves break depends upon the breaker height primarily, but the bottom slope and deepwater steepness have some effect.

Waves breaking at an angle with a shore line produce a littoral current in the direction of the component of the wave velocity. Facing seaward, if oblique waves break first to the right, and the point of breaking then progresses to the left, the current will run from right to left. The strength of the littoral current depends upon the breaker height, the breaker angle and the average slope of the bottom from the breakerline to the shore. The littoral current fluctuates in velocity, being strongest just after a wave breaks.

The turbulence induced by the breakers and the strong and abrupt variations in pressure on, and within, the bottom throw bottom sand into suspension. This sand then moves with the surrounding water as it settles and a littoral drift of sand occurs, if there is a littoral current. The bottom, being constantly agitated by breakers, tends to adjust its profile to correspond with each wave condition, sand moving from the shore seaward, or the reverse, depending on the existing combination of height and period. The rise and fall of the tide moves the breakerline back and forth and produces some change in the profile, particularly in the position of the inshore bars.

Near tidal entrances or in channels connecting tidal seas, tidal currents are superimposed on the wave-induced littoral currents. On the flood tide, the currents near the shore are directed toward the entrance, while on the ebb tide there is a tendency toward "jet action" which also induces currents toward the entrance.

Sources and Rates of Littoral Drift.—Erosion of the land surface and transportation of detritus by streams and rivers is the principal source of the unconsolidated material found on the shore line. Direct erosion of the shore provides material and, if the upland eroded is sandstone or conglomerate, this source may dominate in some areas. Measurements of the volume of material transported by rivers are not entirely reliable because of the difficulty of determining the amount of the heavy fraction moved along the bed, and it is this fraction which is of the size and character suitable for beach formation. Estimates of the bed movement of the Columbia river, based on laboratory studies of sand movement and field measurements of currents, indicated that the average was of the order of 10,000,000 cu.yd. per year.

Studies of small coastal drainage basins in southern California indicated debris production as high as 100,000 cu.yd. per square mile in one torrential rain. An average of 1,000 cu.yd. per year per square mile is not unusual. Cliff erosion, though occasionally spectacular, does not usually proceed rapidly enough to account for known rates of littoral movement.

Littoral movement of material shows daily, seasonal and annual variations corresponding to the variations in the direction and intensity of wave attack. Measurements of the rate of littoral drift are possible only where the accumulation can be measured at the beginning and end of a period during which the direction of movement does not reverse. Breakwaters and other large structures do provide suitable measuring basins, but only rarely is it known that the direction and rate of movement have been substantially constant between surveys of the accumulation.

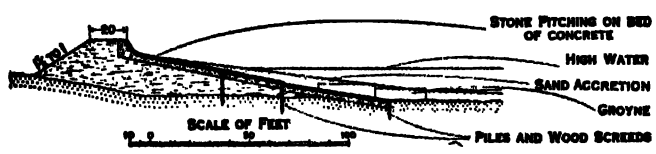

FIG. 2.—SEA WALL AT DYMCHURCH, KENT

At Santa Barbara, Calif., the situation is ideal for measuring the rate of littoral drift. A breakwater extends seaward of the zone of appreciable sand movement. The Channel Islands shield the shore line and waves approach the shore line from a westerly quarter on all but a few days of each year. The drifting material moves from west to east around the end of the breakwater and accumulates in the harbour area, whence it is removed biennially by dredging and placed on its leeward beach. Rates of movement from west to east at this locality have been as high as 1,480 cu.yd. per day, and the average over a period of 17 years was 775 cu.yd. per day.

Measurements and estimates of the rate of littoral sand movement at other localities are not as reliable or extensive as at Santa Barbara but their magnitude is of some interest. At Santa Monica, Calif., measurements of the accumulation in the lee of an offshore breakwater showed a littoral movement from north to south of 780 cu.yd. per day average over ten years. Along the south shore of Long Island, the sand moves from east to west at the average rate of about 1,000 cu.yd. per day. The

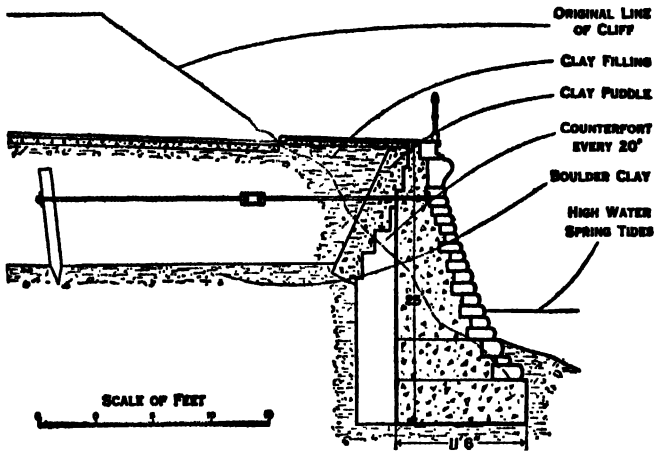

FIG. 3.—SEA WALL AT BRIDLINGTON, YORKSHIRE

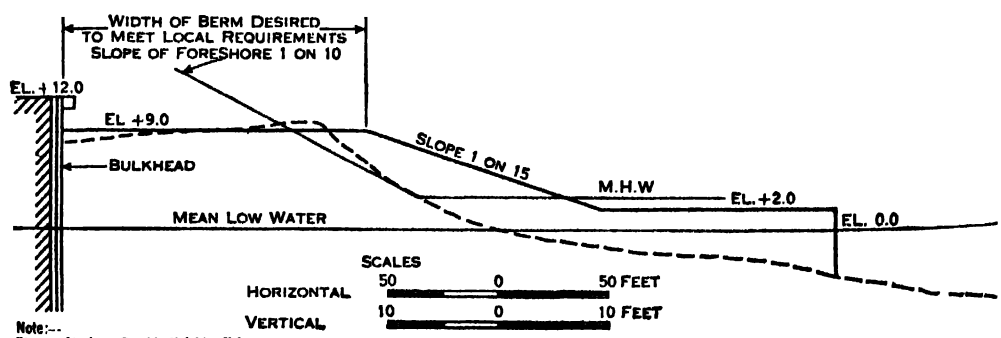
rates of littoral movement cited are intended to be illustrative only and should not be regarded as applying to other locations where the sand size, bottom slope and exposure to wave attack are different. Furthermore, they are averages over relatively long periods; the short period rates may be much greater, and seasonal variations in wave attack may also produce a change in the position of the shore line and of the inshore portion of the bottom profile. The beach is frequently found to be wider in summer than in winter, the change being the result of movement of sand to the shore face from offshore bars. This seasonal variation amounts to as much as 300 ft. at some points along the California coast, but generally the seasonal shift in the position of the shore face ranges from 50 to 100 ft.

Coastal erosion results when the rate of removal of material, either directly seaward or along the shore line, exceeds the rate of supply. When these rates are equal, the shore line is in equilibrium; when the supply exceeds the loss, accretion results. Continued erosion of the unconsolidated shore material will ultimately expose cliffs or upland to direct wave attack.

COAST PROTECTION

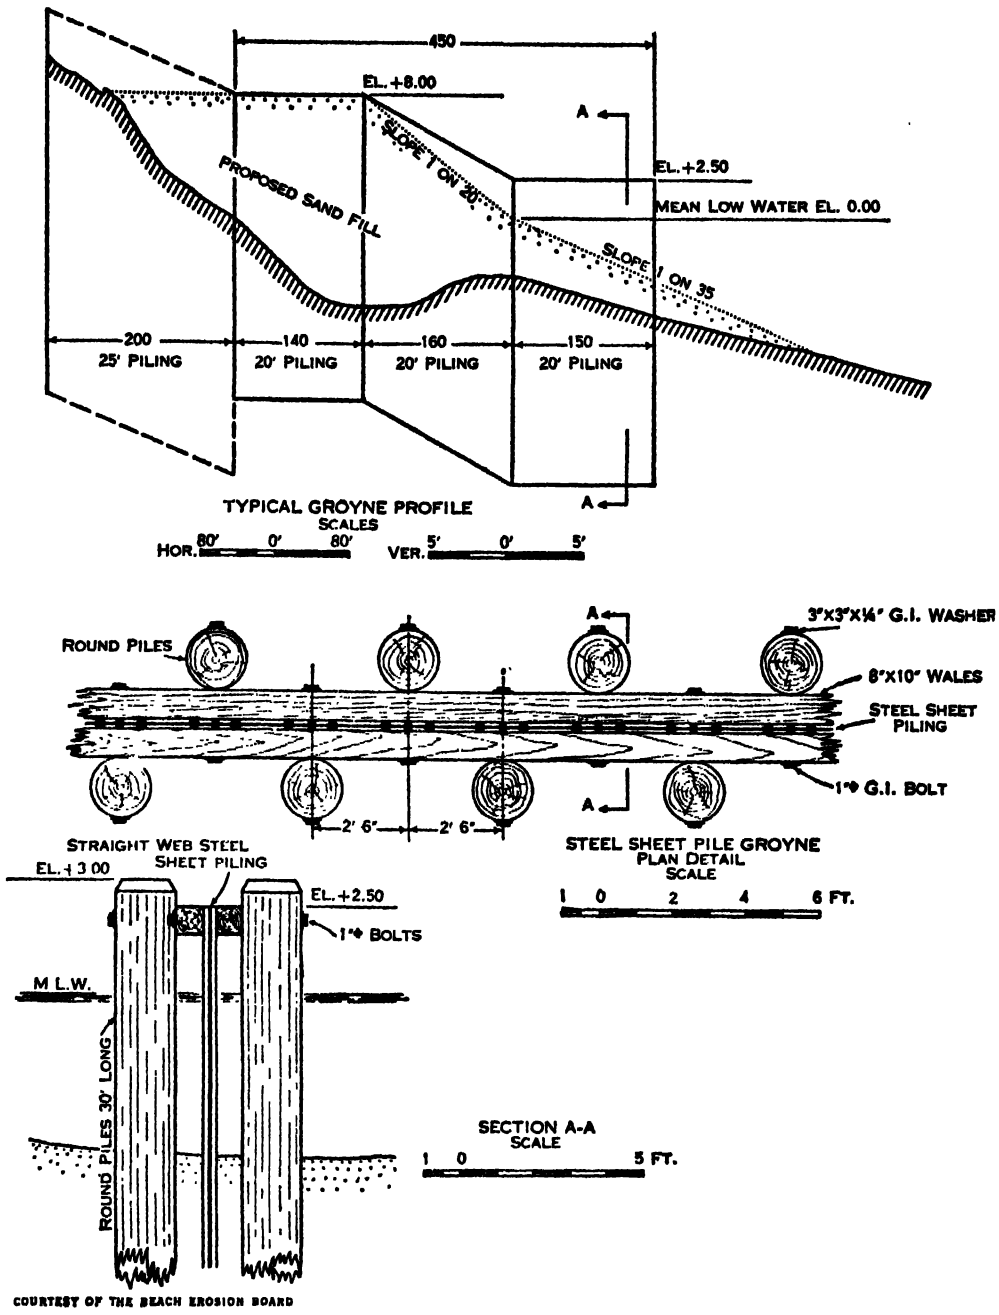
The design and planning of coast protection should consider: (1) the value of the land and improvements to be protected; (2) the direction and magnitude of the littoral drift; (3) the intensity of wave attack; and (4) the erosional history of the locality. The wisest and most economical policy is to leave the sea adequate "elbow room." However, for various reasons protective works are desired. In spite of extensive studies of the phenomena involved, the planning of these projects depends more on judgment and intuition than on scientific analysis and conservative designs, and ample cost estimates are recommended.



Sea Walls.—Fixation of the margin between land and sea is accomplished by building sea walls or bulkheads. Cast concrete, concrete piles, masonry, random stone, steel sheet piles and timber piles are employed, the choice depending on the costs and exposure. The conditions affecting the design of a sea wall differ so materially that every case must be considered on its merits and provided for accordingly.

Waves break in a depth of water which depends primarily on their height; the deeper the water the larger the breaker which can occur. The deepest water will occur at a sea wall or bulkhead at the time of highest tide, including wind-tide effects. Design must be adequate to withstand both the maximum wave forces and the overturning moment caused by saturated backfill on the land side. Footings must be deep enough to sustain the structure under the worst scouring conditions anticipated during the life of the structure.

Inundation of Galveston, Tex., during the hurricane of 1900 led to the construction of a sea wall of the section shown in fig. 1. Along most of the length of this wall a beach exists at normal water stages, and waves do not reach the wall. During hurricanes the tangential force of the wind causes water to pile up against the shore and also generates large waves which break against, or over, the structure. This intense wave attack continues for only a few hours and the probability of full hurricane force at this particular point is of the order of once in eight years.



Many sea walls and bulkheads have been built for the purpose of protecting roadways or buildings from the limit of wave uprush at the highest tide, and their exposure is such that relatively light construction is justified. Locations farther seaward require heavier construction and greater attention to foundation conditions. Since waves are variable in height and are superimposed on a tide, there are many conditions of exposure to be considered. The destructive effect of waves depends both upon wave force and frequency of exposure. Waves of moderate size breaking directly against a sea wall for long periods may produce more damage than would larger waves over a short period. The destructive force of breakers exhibits two components, namely, a short sharp impact force which may dislodge stones or crack concrete, and an impulse of long duration which tends to move the structure as a whole. Both components appear to reach their maximum intensity when the face of a plunging breaker strikes against a solid surface parallel to itself. The illustrations show various designs employed to avoid these maximum forces.

Some authorities state that sea walls cause scour, while others claim that they cause fill. Both views may be correct, depending on circumstances. Just as in the case of unprotected shore lines, the profile of the bottom in front of a sea wall depends upon the tide stage and the wave characteristics. Under some conditions sand will be moved to the wall, while under others it will be moved away. It is always desirable to maintain a blanket of sand in front of a sea wall to induce breaking at a distance from the wall, and for this purpose, groynes are frequently used if the littoral drift is sufficient to keep them full. Where scour is progressive and the littoral drift is insufficient to fill groynes, random stone is effective in front of sea walls for the purpose both of reinforcing the foundations and of taking the brunt of wave attack. In the United States, random mound walls are preferred both because they can be repaired readily and because

COURTESY OF THE BEACH EROSION BOARD

FIG. 4.—TYPICAL GROYNE DESIGN OF THE BEACH EROSION BOARD

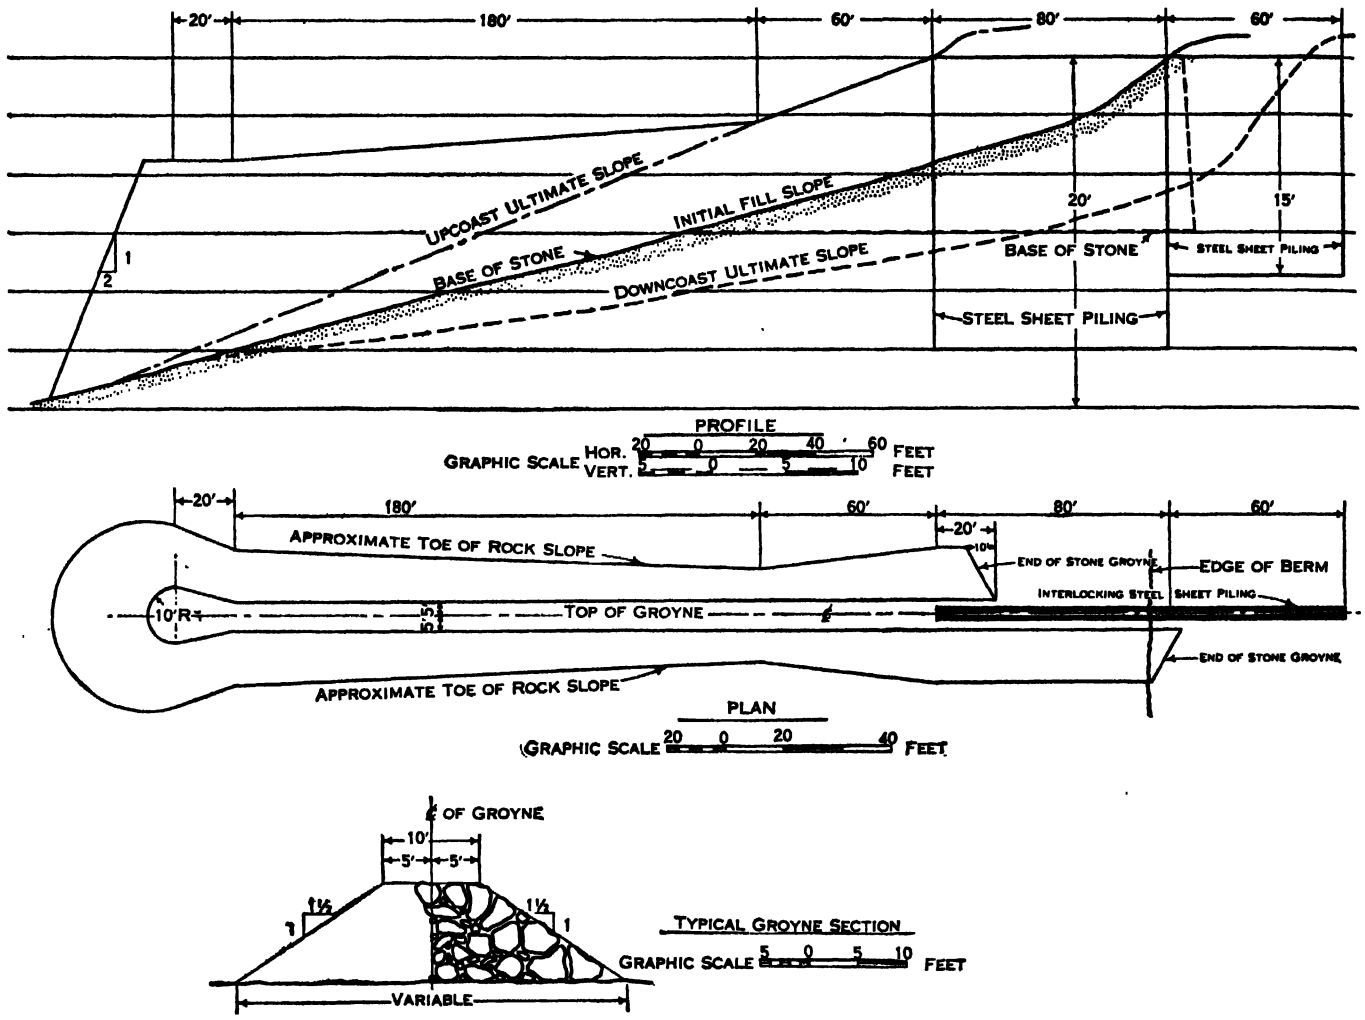
COURTESY OF THE BEACH EROSION BOARD

FIG. 5.—STEEL SHEET PILE GROYNE

they can be constructed with heavy machinery and a minimum of labour.

Groynes (Groins).—Short, low structures built perpendicular to the shore line for the purpose of retarding the littoral drift, and thus widening or maintaining a beach, are known as groynes. Fig. 4 shows the profile recommended by the Beach Erosion board, while fig. 5 and 6 show typical designs. Evidently, the construction of groynes assumes the occurrence of a littoral drift of sand sufficient to fill them. The spacing and length of groynes depend chiefly on judgment based on local experience. During periods of erosion, groynes may be flanked by wave attack; and once flanked they are not likely to refill. For this reason groynes are generally connected to a bulkhead at the shore end, this arrangement being more economical and giving a better appearance than would be obtained if the groynes were extended landward far enough to preclude being flanked.

Unless an artificial supply is provided, the sand required to fill a groyne field is withdrawn from the littoral drift and the shore line to the leeward, if previously in equilibrium, will suffer some erosion. The individual groynes should allow wave wash and sand transport over them, and a groyne field should be constructed gradually so as not to trap an unduly large amount of sand in a short period. A desirable procedure is to build the leeward groyne first, and then add groynes to windward (direction from which littoral drift moves).



Jetties.—Large structures built generally perpendicular to the shore line are called jetties. Frequently they extend far enough seaward to intercept the littoral drift completely, causing accretion to windward and erosion leeward. Examples of this effect are the jetties at Santa Barbara, where the accumulation has been very extensive. No feasible natural method has been discovered to move sand past such structures, except by allowing them to sand up and thus lose their effectiveness. The solution developed has been to pump the sand across the structure either continuously or periodically. This by-passing operation is essential because erosion to leeward will progress for miles. The erosion extended ten miles east of Santa Barbara in the ten years following construction of the breakwater.

Offshore breakwaters, such as that at Santa Monica, were thought at one time to obviate the problem of accretion to windward and erosion to leeward, but a consideration of the phenomena involved will show that this conclusion is erroneous. The offshore breakwater must reduce wave action to be effective, and must therefore produce a local reduction in the littoral drift in the protected area as compared with the movement on each side. Sand accumulates in the lee and then acts as a groyne against which the shore line fills to windward. Erosion must occur to leeward because the transporting forces are unchanged while the supply is reduced.

Artificial Beaches.—The cost of construction and maintenance of groynes, jetties and sea walls led to an increasing use of artificial fills as means both of providing beach areas and of protecting the adjacent upland. An example of this practice is the fill in Santa Monica bay, Calif., where 14,000,000 cu.yd. of material were sluiced out of the sand dunes and deposited by pipe line to form a beach approximately 500 ft. wide and several miles in length. In its ultimate development, this project was designed to provide a fill 1,000 ft. wide. Wastage of material from the seaward face of these artificial fills is difficult to estimate, and may prove to be the principal maintenance cost. (M. P. O'B.)

RECLAMATION

The main objects of reclaiming land from the sea are: (1) to increase the area of ground available for cultivation; (2) to gain land of high potential value for some industrial purpose or for municipal expansion. Examples of the first are the fenland reclamations, the embanking and reclaiming of Sunk Island in the Humber river and the great Zuider Zee reclamation which

COURTESY OF THE BEACH EROSION BOARD

FIG. 6.—COMPOSITE RANDOM MOUND AND STEEL SHEET PILE GROYNE

was begun in 1920. The reclaiming of nearly 300 ac. of foreshore by the construction of a costly sea embankment at Hodbarrow in Cumberland for the purpose of mining iron ore under the foreshore and sea bed was an example of reclamation for industrial purposes. The reclaiming of the foreshore at Back bay on the west side of the Colaba peninsula at Bombay, begun after World War I, was a notable undertaking connected with city expansion. The high cost of labour and materials compared with the value of agricultural land rendered works of reclamation solely with the object of cultivation, often unremunerative.

Reclamation in Estuaries.—Accretion is the increase of land areas brought about by natural forces; *e.g.*, the deposit of silt in estuaries. Land which has been raised by accretion nearly to high-water level can be shut off from the sea by works of a simple nature and the fresh alluvial soil thus obtained is generally very fertile. Accretion in estuaries is a slow process under ordinary conditions. As soon, however, as a fixed channel is secured by longitudinal embankments or training walls, accretion progresses rapidly by the deposit of sediment in the slack water behind the embankments. Ultimately the time arrives when the water may be altogether excluded by the construction of enclosing embankments; these must be raised above the level of the highest tide, and should have a flat slope on the exposed side, protected, in proportion to exposure and depth of water, with clay, sods, fascines or stone pitching.

In the intermediate stages of the process outlined above much may be done to promote the growth of accretion, or warping as it is termed, and to ensure the fertility of the reclaimed land. The deposit of warp is accelerated by anything which tends to reduce the flow and consequent scour of the ebb tide over the foreshore: thus considerable advantage will accrue from placing rows of faggots or sods across the lines of flow. The light, fertilizing alluvium only deposits in shallow water at high tide and where there are no tidal currents.

The final enclosure, therefore, in the case of land intended for cultivation, should not be effected until this deposit has taken place. A final and rapid deposit can sometimes be effected by making sluices in the banks: the turbid water is admitted near high tide, and retained until the whole of its silt has been deposited, the clear water being allowed to escape slowly toward low tide. Premature enclosure must be guarded against; it is more difficult, the cost greater, the reclaimed land is less fertile and, being lower, less easy to drain.

The practice of reclaiming land in British estuaries is a very ancient one. The Romans effected reclamations in the fen districts, in Romney marsh and near Winchelsea; the enclosing of Sunk Island in the Humber was begun in the 17th century; large reclamations in the Dee estuary took place in the 18th century; and, in later times, works were carried out in the estuaries of the Ribble, Tees and other rivers. The bulk of the later work was with the object of industrial development. For instance, in the Tees estuary large areas of foreshore were reclaimed for factory sites and other industrial purposes by forming banks of iron slag obtained from the ironworks of the Middlesbrough district. Slag constitutes an excellent material for the construction of reclamation banks in localities where it can be obtained at a low cost near the site of the works. The deposit of alluvial material, during and after embanking, is not an important factor in reclamation for industrial purposes and where the levels of land have to be raised it is usual in such cases to effect this

by the artificial deposit of filling material.

Seacoast Reclamation.—In the reclamation of land adjoining the open coast, sites where accretion is taking place are

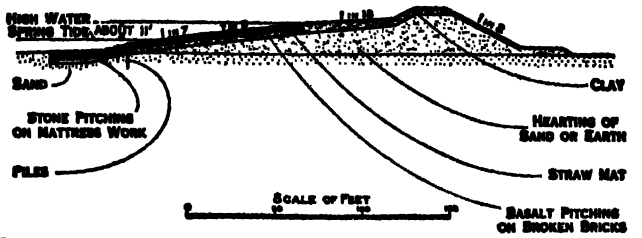


FIG. 7.—CHARACTERISTIC CROSS-SECTION OF DUTCH SEA EMBANKMENT OR DIKE

obviously the most suitable. Marsh lands adjoining the sea, and more or less subject to inundation at high tides, can be permanently reclaimed by embankments; but these, unless there is protection by sand dunes or a shingle beach, are required to be stronger and higher, with a less steeply inclined and better protected slope than is required in estuaries. Waves overtopping the bank will quickly cause a breach, and produce disastrous results; the height of the bank must, therefore, be calculated to meet the case of the severest onshore gale coinciding with the highest spring tide.

Seacoast embankments should not generally be constructed farther down the foreshore than half-tide level, as the cost of construction and maintenance would increase out of all proportion to the additional area obtained. It is, as a rule, more economical to reclaim a large area at one time, instead of enclosing it gradually in sections, as the cost varies with the length of embankment; it is, however, more difficult to effect the final closing of a bank, where a large area is thus reclaimed, on account of the greater volume of tidal water flowing in and out of the contracted opening. The final closing of a reclamation embankment is best accomplished by leaving a fairly wide aperture, and by gradually raising a level bank across its entire length. The embankments in the Netherlands are closed by sinking long fascine mattresses across the opening; these are weighted with clay and stone, and effectually withstand the scour through the gap; the two terminal slopes of the finished sections are similarly protected.

There are many examples of seacoast reclamation: Romney marsh was enclosed long ago by the Dymchurch wall, where the method of protection adopted more nearly resembles the Dutch system than any other work in Great Britain and a large portion of the Netherlands has been reclaimed from the sea by embankments; the reclamation bank for the Hodbarrow iron mines illustrates the use of puddled clay to prevent infiltration. The outer portion of this embankment for a length of more than 3,000 ft. was protected on its sea face by concrete blocks, each weighing 25 tons, deposited as a random mound (fig. 8). The sea embankment of the Back bay reclamation at Bombay (*q.v.*) is an example of modern construction on a rocky foreshore.

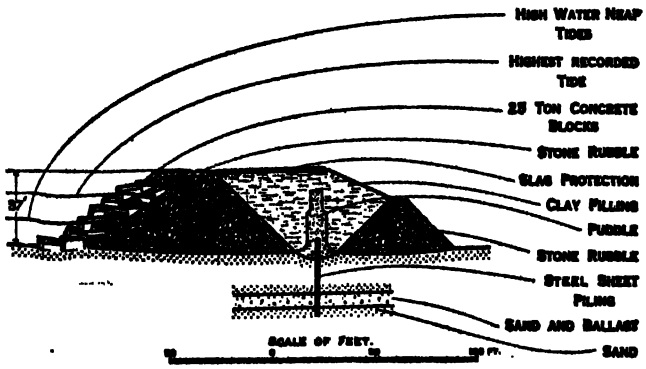

FIG. 8.—RECLAMATION BANK FOR THE HODBARROW IRON MINES, 1904

Breaches in Embankments.—The repair of a breach effected in a completed reclamation embankment is a more difficult task than that of closing the final gap during construction; this is because of the channel or gully scoured out upon the opening of the breach. When a breach occurs which cannot be closed in a single tide, the formation of an overdeep gully may to some extent be prevented by enlarging the opening. Breaches in embankments have been closed by sinking barges across the gap, by piling and planking up, by lowering sliding panels between frames erected to receive them and by making an inset wall of bank round the breach.

The gradual drying of reclaimed land lowers the surface about two or three feet; the land therefore becomes more liable to inundation after reclamation than before. Accordingly, it is most important to prevent breaching of the bank by promptly repairing any damage caused by storms; and if a breach should occur, it must be closed at the earliest possible opportunity.

Reclamation by Dredging.—Mention should be made of the method of reclamation by dredging material from the bed of the sea or a river and depositing it on shore or behind an embankment for the purpose of raising the level of existing land or converting foreshore or sea bed into dry land. The method was first used on a large scale in the Netherlands toward

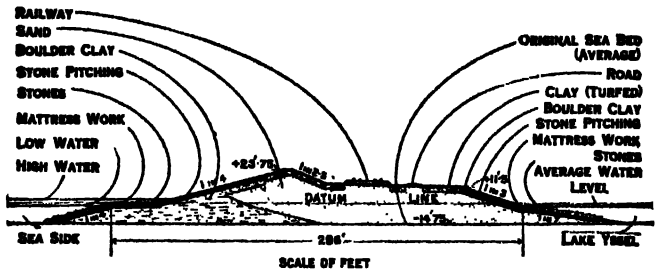

FIG. 9.—CHARACTERISTIC CROSS-SECTION OF THE MAIN SEA DIKE IN THE RECLAMATION OF THE ZUIDER ZEE

the end of the 19th century and was later extensively employed in many parts of the world (*see* DREDGERS AND DREDGING). The material, whether sand, silt, clay or gravel, is dredged from the sea or river bed by a bucket dredger or a suction dredger. If the former is employed the dredged material is usually delivered into barges and conveyed to a pump-ashore station, where admixture with water takes place, and a pump forces the mixture through a line of pipes on to the land to be reclaimed. If suction dredgers are used for gaining the material it can be pumped ashore direct through floating pipe lines, if the distance is not too great, or transported by barges from which it is pumped ashore by means of a fixed or floating reclamation pump. In some instances an intermediate pumping station in a long line of delivery pipes has been used to boost (*i.e.*, to speed up or relay the flow through the pipes) the mixture of water and dredgings delivered to it from the main dredger. A notable example of the reclamation of tidal areas by dredged fill is San Francisco bay.

THE NETHERLANDS AND BELGIUM

A large part of the Netherlands and some portions of Belgium are below the normal sea level and are protected from inundation by artificial embankments (dikes) or by narrow belts of sand dunes. The foreshore works on the coast of the Netherlands and Belgium, although of great interest and attended with considerable success, do not afford examples to be followed as affecting the sea defenses of Great Britain and other countries exhibiting physical characteristics similar to those of the latter. The protection works in such cases as Blankenberghe, Heyst, Scheveningen, Kallantsoog and Petten are of great magnitude and the engineers responsible for these works, particularly in the Netherlands, have at their command the accumulated experience of centuries of sea-defense work. The local conditions with which these works have to conform, viz., low flat foreshores consisting entirely of sand, are wholly different from those generally associated with sea-defense works in England. The large expenditure involved is justified by the necessity of securing the safety, not only of the seaboard, but of large tracts of the countries themselves. Investigations in

the Netherlands are said to indicate a continuous subsidence of the land of that country relative to the sea level, amounting to about 5.91 in. per century.

The North sea foreshores of the Netherlands and Belgium consist for the most part of fine sand; similar deposits border the

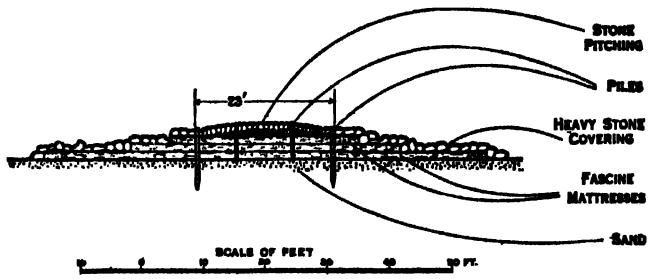

FIG. 10.—CHARACTERISTIC CROSS-SECTION OF MATTRESS GROYNES ON THE NORTH COAST OF THE NETHERLANDS

lower portions of the numerous river estuaries which penetrate far inland, but in the higher parts of these the foreshores are generally composed of fine sand covered with clay or mud. The foreshores of the North sea between high and low water have an average gradient of about 1 in 45 and the shores above high water normally slope at about 1 in 25. Submerged sandbanks more or less parallel to the shore are a characteristic feature of the North sea and estuary coast lines of the Netherlands and Belgium. These, where they exist, afford considerable protection to the sandy shores during onshore gales. In calm weather and with offshore winds sand accumulates on the foreshores.

The most important forms of sea defense works in common use in the Netherlands are: (1) groynes; (2) sea walls or dikes; and (3) fascine mattresses with stone ballasting for the protection of submerged banks.

Groynes.—Groynes are usually constructed at right angles to the shore line and are maintained as a rule at a small height above the average foreshore level. On those portions of the North sea coast which are most exposed, groynes are placed about 250 m. apart and are extended out beyond the low-water line. Many of the groynes on the Dutch coast are constructed of layers of fascine mattresses covered by heavy stone, having their crests almost flat or turtle-backed with side slopes of 1 in 2, or flatter. The fascine or brushwood mattresses are held together and pinned down by rows of piles. Wide brushwood aprons, with heavy stone covering forming flat slopes, are constructed on either side of the groyne in order to protect the flanks against scour (fig. 10). The groynes are carried up above the line of high water to meet the base of the sand dunes or the protecting dikes. These groynes, inclusive of the side aprons, are often of considerable width, sometimes as much as 32.81 yd. at their deepest and widest parts.

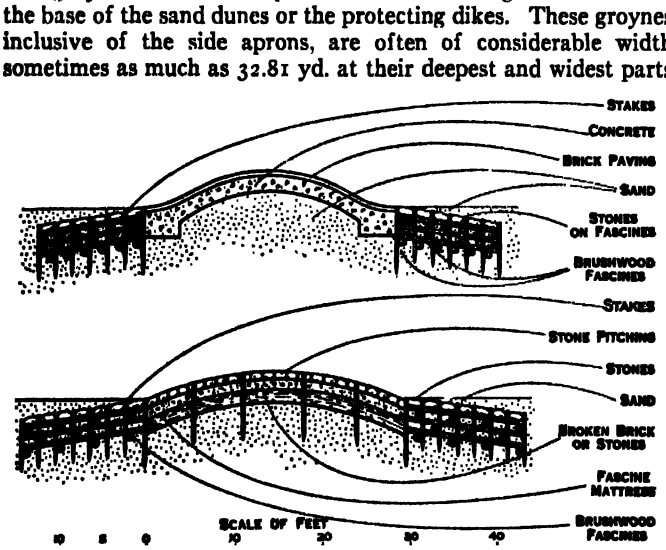

FIG. 11.—CHARACTERISTIC CROSS-SECTIONS OF GROYNES AT OSTEND AND BLANKENBERGHE, BELGIUM

On the coast of Belgium at Blankenberghe and in its vicinity the shore is groyned on an extensive scale. The groynes on the average are about 820 ft. long and 680 ft. apart; they resemble the typical Dutch groyne in form and are constructed with a foundation of mattress work or concrete, faced with brickwork or stone pitching (figs. 10 and 11).

Dikes.—On much of the North sea coast line of the Netherlands and Belgium, where the beach is protected from erosion by groynes, the sand dunes or the coastal embankments (dikes) are frequently protected by a flat slope of brickwork, or basalt or other stone pitching, or concrete slabs laid on beds of clay, rubble and mattress work (fig. 7). In situations, such as Scheveningen and Ostend, where a promenade has been formed on the sea embankment, a curved faced wall is sometimes substituted for the upper part of the normal slope of the paving thus reducing the width of the protecting works; but over large stretches of coast, particularly in the Netherlands, a simple flat paved slope is the common practice.

Protection of Submerged Banks.—The underwater banks of some of the estuary channels and sea inlets on the Dutch coast often stand at a steep slope with deep water alongside. Under these conditions there is serious liability to erosion and it is usual to protect the banks both above and below water by artificial means. For many years fascine mattresses have been used for this purpose. These are made upon a convenient sandy foreshore, covered at high tide, and, when completed, are towed to the place where they are to be used and sunk on the sea bottom by ballasting with stone. They consist of two layers or grids of brushwood each built up of crossed rows of parallel brushwood ropes, 0.4 yd. circumference, and spaced 0.98 yd. apart centre to centre, bound tightly together with a filling of brushwood in three layers between them. On the top of the upper brushwood grid, openwork partitions are formed for the reception of stone ballast. Formerly, clay mixed with a little stone was used for ballasting, but in modern practice stone alone is employed, the mattresses being weighted to the extent of 184 lb. per square foot. The cost of continuous protection of the steep banks of the estuary channels, where the depth of water alongside is sometimes as much as 100 ft., is very

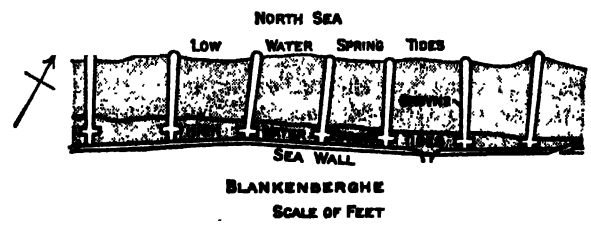

FIG. 12.— PLAN OF GROYNES ON NORTH SEA COAST AT BLANKENBERGHE, BELGIUM

considerable. In some localities the cost has been reduced by the construction of intermittent mattress work, leaving short unprotected stretches of bank between projecting spurs which serve to deflect the main current away from the unprotected embayments. In cases where the sea bed of the deep channels consists of clay, erosion is not so uniform as that of sandy bottoms and the side slope is sometimes very steep, exceeding 1 to 1 in certain cases. In such situations rubble stone ballasting or surfacing of the bank is preferred to the employment of mattresses. (In Great Britain stone protection of this nature is known as "revetting.") The protection of the shore lying between the steep submerged and partially submerged banks of the channels and the base of the dike or wall which forms the immediate protection of the land behind, is usually effected by means of groynes. These shores, which are sometimes of considerable width above the level of normal high water, have in most cases flat gradients.

Reclaiming of the Zuider Zee.—The partial reclamation of the Zuider Zee, undertaken by the Dutch government in 1918, is the greatest work of its kind ever attempted. The earliest plans for regaining the submerged lands of the Zuider Zee date from the 17th century, but it was not till the middle of the 19th century that serious proposals began to be considered. Among these plans were those of van Diggelen, 1849, Leemans, 1877, and the various

schemes of the engineer C. Lely, subsequently minister of public works, which appeared between 1887 and 1891; the last of which is substantially that on which work was actually commenced in 1920. The finally approved scheme is shown in fig. 13. (*See* ZUIDER ZEE.)

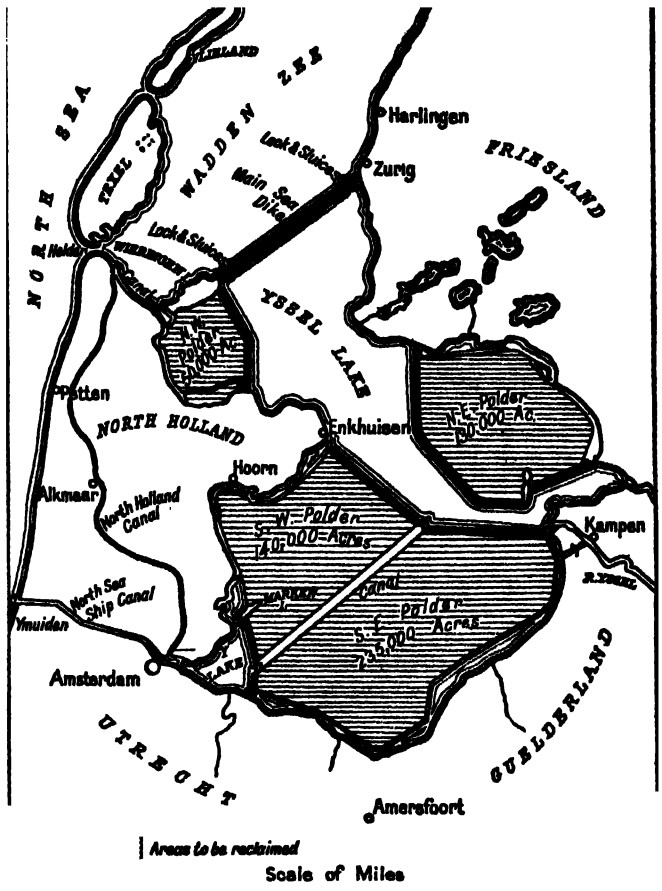

FIG. 13.—SKETCH PLAN FOR THE RECLAMATION OF THE ZUIDER ZEE

BIBLIOGRAPHY.—The *Reports and Evidence: Royal Commission on Coast Erosion and Reclamation of Tidal Lands*, particularly the final report, Cd. 5,708 (1911), should be consulted both for coast erosion and reclamation. Vol. i, pt. 2, i, Cd. 3,684 (1907), contains a useful bibliography by W. Whitaker, F.R.S., up to 1906. The bibliographic lists issued by the International Association of Navigation Congresses, Brussels (since 1908) are very complete. Another good bibliography of works in English was issued by the Engineer School Library, Washington, D.C., in 1926. W. H. Wheeler, *The Sea Coast* (1902); A. E. Carey and F. W. Oliver, *Tidal Lands* (1918); D. W. Johnson, *Shore Processes and Shore Line Development* (1919). Periodical reports of the Beach Erosion Board, Washington, D.C., should be consulted for conditions in the United States. For the Netherlands *see* papers by A. T. de Groot in *De Ingenieur*, no. 35 (1911), and R. P. J. Tutein in *Die Gids*, no. 3 and 5 (1913). Samuel Smile's *Lives of the Engineers* contains good accounts of early reclamation works. *See* also E. M. Ward, *English Coastal Evolution* (1922); W. H. Wheeler, *History of the Fens* (1897) (contains a bibliography of Fenland literature); and *Proceedings Inst. C. E.* (*passim*). (N. G. G.; X.)

COATBRIDGE, a large burgh, having the privileges of a royal burgh, Lanarkshire, Scotland. Pop. (1951 census) 47,538. It is situated on the Monkland canal, 8 mi. E. of Glasgow, with stations on the Scottish Region railway route. Until about 1825 it was only a village, but since then coal and iron mining have been developed, and it is now a centre of the iron trade of Scotland. Its prosperity was largely caused by the ironmaster James Baird (*q.v.*). The industries of Coatbridge produce malleable iron and steel boilers, tubes, wire, tinplates and railway cars, tiles, fire-bricks and fire-clay goods. The town, which became a municipal burgh in 1885, forms with Airdrie one of the parliamentary divisions of Lanarkshire. About 4 mi. W. by S. lies the coal-mining town of Baillieston.

COATES, ALBERT (1882–1953), English conductor and composer, was born at St. Petersburg, Russia, April 23, 1882, and was sent to school in England when he was 12. He later studied at Liverpool university and at the Leipzig conservatory, where he had his first experience of conducting as coach at the opera under Arthur Nikisch. He became conductor at Elberfeld in 1906 and joint conductor with Ernst von Schuch at Dresden in 1908. During 1910–15 he was conductor of the Imperial opera at St. Petersburg. He visited England occasionally but in 1919 made it his headquarters, establishing an international reputation, particularly as interpreter of the works of Richard Wagner and Alexander Scriabin and other Russian composers. During 1923–25 he was director of the Philharmonic orchestra at Rochester, N.Y. In 1936 he conducted an opera season at Covent Garden, which included his own opera, *Pickwick*. Another opera, *Samuel Pepys*, had been produced at Munich in 1929. In 1946 he settled in South Africa, and he died at Milnerton near Cape Town, on Dec. 11, 1953.

COATES, JOSEPH GORDON (1878–1943), New Zealand statesman, was born at Matakohe, the son of a farmer. He was elected M.P. for Kaipara in 1911, and impressed his leader, W. F. Massey, with his solid ability. From 1917 to 1919 he served with distinction in France. In 1919 he joined the cabinet and, as head of the public works, railways and other departments, proved himself a capable administrator. During 1925–28 he was prime minister, and a privy councillor from 1926. An important part of his policy was the consolidation and development of industries. He was minister of public works in 1931–33 and finance minister in 1933–35. He attended imperial conferences in 1926, 1932 and 1935. He was a member of the New Zealand war cabinet, and was made minister of armed forces and war co-ordination on July 1, 1942. He died in Wellington on May 27, 1943.

COATESVILLE, a city of Chester county, Pennsylvania, U.S., on the west branch of Brandywine creek, 38 mi. W. of Philadelphia. It is on federal highway 30 and is served by the Pennsylvania and Reading railways. The population in 1950 was 13,826 and in 1940 was 14,006 by the federal census. It has important steel plants, in addition to numerous other manufacturing industries. The annual factory output was valued at about $70,000,000 at mid-20th century. Coatesville was founded about 1800, and was named after Jesse Coates, one of the early settlers.

Coatesville was chartered as a city in 1915.

COATI, or COATI-MUNDI, the name of the members of the South and Central American genus *Nasua*, of the mammalian family Procyonidae. They are recognized by their long body and tail, and elongated, upturned snout. The tail is often prominently banded. Coatis are gregarious and arboreal in habit, and feed on birds, eggs, lizards and insects. They are often tamed as pets. (*See* CARNIVORA.)

COATS, J & P., Limited. This now world-famous thread concern was founded in Paisley in 1830 by James and Peter Coats to carry on the business established in 1826 by their father James Coats (1774–1857). The small factory built in 1826 still forms a diminutive part of the vast works at Ferguslie, Paisley. There was keen and at times bitter rivalry between J. & P. Coats and another local manufacturer—Clark & Co.—which continued until 1896 when the two firms amalgamated in the name of the former.

At the same time control was acquired of the two leading manufacturers in England—James Chadwick & Brother and Jonas Brook & Brothers—and the Central Agency, Ltd., was formed to take over the marketing of the product.

The combine made rapid progress, particularly in building up a large export trade, and with a subscribed capital of £20,250,000 in 1939 owned or was associated with the ownership of manufacturing units in about 43 countries, and had selling agencies in every country in the world. Sewing cotton for domestic and commercial use remained the main product of the company, but a large number of fancy threads for embroidery purposes and to a lesser extent silk and rayon threads were introduced.

It is of interest to note that although there have been many

improvements made in the machines used in the manufacture of cotton thread, there have been no revolutionary changes in the method of manufacture, and the process at mid-20th century was substantially the same as it was at the beginning of the 19th century.

COB, something round, stout, tufted or like a head (possibly from Ger. *Kopf,* head). The principal uses of "cob" are for a stocky, strongly built horse, from 13 to 14 hands high, a small round loaf, a round lump of coal, in which sense "cobble" is also used, the central part of the fruiting spike of the maize plant, and a large nut of the hazel type, commonly known as the cobnut. The fruiting spike of Indian corn is called corn on the cob.

COBALT, a mining town on Cobalt lake, Timiskaming, northern Ontario, Can., 330 mi. N. of Toronto, on the Ontario Northland railway. Unknown till 1903, it subsequently became the centre of one of the richest silver districts in the world. The region also produces cobalt, arsenic and nickel in large quantities. Pop. (1951) 2,230.

COBALT is a metallic element (symbol Co, atomic number 27, atomic weight 59.94) placed in the periodic system in Group VIII between iron and nickel, both of which it closely resembles. The atomic weight of cobalt is slightly higher than that of nickel, which it precedes in the periodic classification. This is because of the fact that cobalt is composed of two isotopes, 57 and 59, and the abundance ratio is 0.2 to 99.8, hence the mean atomic weight is higher than that of nickel, whose lowest isotope, 58, is most abundant. The atomic number and chemical properties also establish the position of cobalt between iron and nickel. The 27 electrons are arranged: $1s^2\ 2s^2\ 2p^6\ 3s^2\ 3p^6\ 3d^7\ 4s^2$, the incomplete third subgroup being characteristic of the "transition elements" (found in the long periods). Cobalt has two valency electrons ($4s^2$) and their removal forms the stable cobaltous ion, Co^{++}, but the electrons of the third subgroup are also reactive, and they are capable of forming bonds, hence cobalt shows the properties common to other transition elements with incomplete inner electronic groups; *i.e.,* variable valency, paramagnetism, highly coloured compounds, and a pronounced tendency to form complex salts.

History.—The word cobalt or kobold is said to have been used in a manuscript of the 14th century to designate a gnome or evil spirit, who lived in the mines in Germany. In the metallurgical treatises of G. Agricola (1530) the term cobalt was applied to certain minerals and ores, partly because they were worthless when smelted, and partly because the health of the miners suffered from the poisonous fumes caused by the arsenic, also present in the ores. These evils were attributed to the gobelin or kobold. The metal was first prepared in an impure state by G. Brandt in 1742. He observed its magnetic properties and high melting point. He also showed that the blue colour of smalt is caused by cobalt.

Occurrence.—Cobalt is widely distributed but not abundant. Workable deposits have been found at Cobalt in Ontario, the principal source of the element at mid-century, in Missouri, New Caledonia, Queensland, Saxony, the Belgian Congo and Chile. The following list of the more common minerals makes evident the frequent association with arsenic:

asbolite	$CoO.2MnO_2.4H_2O$ (from New Caledonia)
cobaltite	$CoS_2.CoAs_2$
erythrite	$3CoO.As_2O_5.8H_2O$
linnaeite	$Co_3S_4(CoS.Co_2S_3)$
skutterudite	$CoAs_3$
smaltite	$CoAs_2$

The percentage distribution in the earth's crust is said to be 1.8×10^{-5} (0.000018%). Cobalt is found in most meteorites, usually alloyed with iron and nickel (0.5% to 2.5% in iron meteorites), and it has been identified in the spectra of the sun and many stars. Traces of cobalt have been detected in many plants and animals, notably in marine algae and Kentucky bluegrass. The role of cobalt and other "trace" elements in these organisms is still obscure.

Production.—Cobalt is a by-product in the metallurgy of ores in which it is associated with arsenic, iron, nickel, copper, manganese (New Caledonia) and silver (the Ontario deposits, where the platinum metals are also a valuable by-product). The metallurgy is complex and varies with the content of the ore, but the essential steps in treating a typical ore are as follows: the crushed and concentrated ore is first roasted in a blast furnace to remove a considerable proportion of the arsenic, and the resulting speiss (chiefly a mixture of metallic arsenides) is heated with sodium chloride to form insoluble silver chloride. The melt is extracted with water to remove soluble compounds of copper, nickel and cobalt, and the silver is recovered from the insoluble residue by treatment with potassium cyanide. Copper is then precipitated from the solution by metallic iron, and the hydrated oxides of cobalt and nickel are precipitated together by caustic soda. In another method, the speiss is treated with sulphuric acid to dissolve silver, cobalt and nickel. The silver is precipitated by aluminum powder and the cobalt and nickel are recovered from the filtrate as before. A fairly accurate separation of cobalt and nickel is accomplished by dissolving the mixed oxides, described above, in hydrochloric acid; the solution is then neutralized by limestone, thus precipitating the iron as hydroxide, and the filtrate is treated with just enough bleaching lime to precipitate black cobaltic hydroxide, $Co(OH)_3$, leaving the nickel in solution.

The following more accurate, but also more difficult and costly, methods of separation are of interest:

1. The mixed oxides are reduced to finely divided metal by producer gas or hydrogen. When the metals are heated to 50° C. in carbon monoxide, nickel is removed as the volatile nickel tetracarbonyl, $Ni(CO)_4$. Cobalt does not form a carbonyl under these conditions. (*See* CARBONYLS, METAL.)

2. A solution of the mixed oxides in hydrochloric acid is treated with an excess of ammonia, and aerated; chloropentammine cobaltichloride, $[Co(NH_3)_5Cl]Cl_2$, is formed, which is precipitated when an excess of hydrochloric acid is added. Nickel remains in solution.

3. Yellow potassium cobaltinitrite, $K_3Co(NO_2)_6$, known as Fischer's salt, is precipitated by the addition of potassium nitrite to a solution of cobalt and nickel containing acetic acid. Nickel again remains in solution.

Cobaltiferous residues from Canada are also smelted, without purification, with iron or other metals for the production of alloys.

Metallic cobalt is obtained readily by reducing its oxides with carbon, hydrogen, carbon monoxide (producer gas or water gas) or aluminum. It may be deposited by the electric current from slightly acid solutions, containing ammonium salts.

Physical Properties.—Cobalt, when polished, is a silver-white metal with a bluish cast. Its physical properties are summarized in the following table:

Density	8.8 g/ml	Specific heat	0.0828
Melting point	1,480° C.	Hardness (Mohr's scale)	5.5
Boiling point	2,415°	Atomic volume	6.68
Atomic radius	1.257 Å		
Ionization potentials	(1) 7.81 v. (2) 17.2 v.		

Electrode potential, for $Co \rightarrow Co^{++} + 2E^\circ = 0.277$

for $Co^{++} \rightarrow Co^{+++} + E = -1.842$

Tensile strength, 60,000 lb. per sq.in.

The metal is malleable, and may be machined. It is somewhat brittle, but the brittleness may be reduced by the addition of a small amount of carbon.

Cobalt metal is strongly magnetic (ferromagnetism) at all temperatures up to 1,150° C.

Radioactive isotopes (55, 56, 57, 58, 60) have been obtained by bombardment methods (artificial or induced radioactivity). The half-life periods vary from 11 minutes to 5.3 years.

There are two allotropic forms of the element, α-cobalt, stable at the ordinary temperature, and β-cobalt, stable at high temperatures. The transition point is about 400° C. X-ray examination has shown that the α-form crystallizes in a close-packed hexagonal lattice, while in the β-form the lattice is face-centred cubic.

Uses.—The uses of cobalt and its compounds are not numerous but are increasing. Electroplating with cobalt has been suc-

cessful. Many ferrous and nonferrous alloys have been made and studied. The alloys with iron have valuable magnetic properties, and are used to make permanent magnets for telephony. Cochrome is a ferrous alloy containing approximately 60% cobalt, 14% to 16% chromium, and 24% iron. It resembles nichrome, and like it is used for electrical heating units. Nonferrous alloys containing over 50% cobalt are used as high-speed cutting tools, which retain their edge and hardness at a red heat. Stellite, cobalt 55%, tungsten 15% to 25%, chromium 15% to 25%, and molybdenum 5%, is the best known alloy of this class. The powerful Alnico magnets are alloys of aluminum, cobalt and nickel.

Cobalt is best and most widely known for the brilliant and permanent blue colour which its compounds impart to porcelain, glass, pottery, tiles and enamels. The pigment generally used in the ceramic industry is smalt, a potassium, cobalt, aluminosilicate, made by heating impure cobalt oxide with quartz and potassium carbonate. Other pigments containing cobalt are Thenard's blue and Rinman's green, made by heating cobalt oxide with aluminum oxide and zinc oxide, respectively, and cobalt yellow, potassium cobaltinitrite, used as a pigment by artists. Cobalt oleate, lineate and acetate are used as driers for paints and varnishes. Certain partly reduced compounds of cobalt have been shown to act as catalysts for the formation of olefine and paraffin hydrocarbons from carbon monoxide and hydrogen (*i.e.*, in the production of gasoline from water-gas).

Chemical Properties.—The chemistry of cobalt shows many resemblances to, as well as differences from, the chemistry of iron and nickel, its neighbours in the periodic system. The stable oxidation states are two and three. The cobaltous ion, Co^{++} (pink), is stable, and nearly all simple salts (chloride, nitrate, sulphate, etc.) belong to this oxidation state. Ferrous, cobaltous and nickelous salts form a closely related group. The cobaltic ion, Co^{+++}, is extremely unstable, and simple cobaltic salts are almost limited to a fluoride and sulphate. In contrast, the ferric salts (Fe^{3+}) are stable in the solid state and in solution. On the other hand, trivalent cobalt forms hundreds of stable complex compounds, chiefly of the co-ordination type (*see* below) which is rather poorly represented in the chemistry of iron, and wholly lacking in that of nickel. Further, rhodium and iridium, two members of the platinum family, stand below cobalt in a vertical column of Group VIII. The valency state of three is the most stable for these metals, and many types of complex derivatives of trivalent cobalt reappear in strikingly similar form among the compounds of rhodium and iridium.

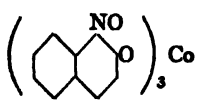
Finely divided metallic cobalt occludes as much as 100 times its volume of hydrogen, and readily gives it up again when heated to 200° C. in vacuo. A pyrophoric form (spontaneously inflammable in the air) is obtained by reducing the oxide at 250° C. The compact and polished metal is not affected by air or water, and only undergoes superficial oxidation when heated to redness in air. The red hot metal reacts with steam, liberating hydrogen and forming the oxide. The metal dissolves in dilute acids, evolving hydrogen, but concentrated nitric acid renders it "passive." Alkalies, either fused or in aqueous solution, are without action. Cobalt combines directly with the halogens, forming the anhydrous blue chloride, $CoCl_2$, the green bromide, $CoBr_2$, and the black iodide, CoI_2. The anhydrous fluoride, CoF_2, is rose coloured.

Carbonyls.—Like nickel and iron, and some other metals, cobalt combines with carbon monoxide, forming carbonyls. These compounds are noteworthy because of their unusual formulas and properties. Under a pressure of 40 to 50 atmospheres, at 150° C., the metal unites with carbon monoxide to form the tetracarbonyl, $[Co(CO)_4]_2$ orange crystals. At 60° C. and atmospheric pressure, this compound is converted to the black tricarbonyl, $[Co(CO)_3]_2$, with loss of carbon monoxide. The volatile derivative, $H[Co(CO)_4]$, has also been reported. All of these compounds are highly toxic.

Oxides.—Cobalt forms three stable oxides, CoO, Co_2O_3, and $Co_3O_4(CoO.Co_2O_3)$; all are grayish black. The first two are also known in the hydrated form, $Co(OH)_2$, pink, and $Co(OH)_3$, black. Cobaltous oxide, CoO, forms many stable salts, but is not a strongly basic oxide. Solutions of its soluble salts are acidic, owing to hydrolysis of the cobaltous ion, Co^{++}. Cobaltic oxide, Co_2O_3, is reduced to the cobaltous state by hydrochloric acid; only complex derivatives are stable. Co_3O_4 crystallizes in octahedra. Its structure, of the spinel type, closely resembles that of magnetite, Fe_3O_4, and it is best represented by the formula $Co_2^{+3}[Co^{+2}O_4]$. A higher oxide, CoO_2, is said to be formed by the action of hypochlorites and other powerful oxidants on cobaltous salts. A few of its derivatives have been reported but all of them are unstable.

Cobaltous Salts.—The cobaltous ion, Co^{++}, is red or pink in dilute solution. As indicated above, hydrolysis of the ion, $Co^{++}+2H_2O \rightleftarrows Co(OH)_2+2H^+$, causes an acidic reaction in solutions of soluble salts. Hydrated salts are red. The chloride, $CoCl_2.6H_2O$, the nitrate, $Co(NO_3)_2.6H_2O$, the sulphate, $CoSO_4.7H_2O$, and the acetate, $Co(CH_3.COO)_2.4H_2O$ are commonly manufactured. Anhydrous salts, such as the carbonate, are generally pink. The hydrated salts assume an intense blue colour when dehydrated by heating, a property utilized in making "sympathetic inks." The sulphate is an exception, the anhydrous form being violet. Many double chlorides, nitrates and sulphates have been prepared. The sulphate forms double sulphates of the Mohr salt class, M'_2SO_4, $M''SO_4.6H_2O$, in which M' may be ammonium, NH_4, K, Rb or Cs, and M'' may be Fe, Co, Ni, Mn, Cr, etc. Double nitrates of the type, $3Co(NO_3)_2.3La(NO_3)_3.24H_2O$, have been used in separations of the rare earths. Cobaltous salts combine with ammonia, pyridine and other organic bases to form complex salts, for example, the hexammine, $[Co.(NH_3)_6]Cl_2$, but these compounds are usually less stable than the corresponding derivatives of trivalent cobalt.

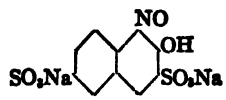
Cobaltic Compounds.—The green fluoride, CoF_3, and the blue sulphate, $Co_2(SO_4)_3.18H_2O$, made by electrolytic oxidation, are the best known simple cobaltic salts. It is noteworthy that the sulphate forms alums, $K_2SO_4.Co_2(SO_4)_3.24H_2O$, which crystallize in deep blue octrahedra. The alums are stable in dry air.



Ammines.—When a solution of a cobaltous salt is treated with an excess of ammonia, with or without the addition of ammonium salts, aerated or oxidized by other agents, and then made acid, depending on conditions, the yellow hexammine cobaltichloride, $[Co(NH_3)_6]Cl_3$ (luteo chloride), the red aquopentammine cobaltichloride, $[Co(NH_3)_5H_2O]Cl_3$ (roseo chloride), or the purple chloropentammine cobaltichloride, $[Co(NH_3)_5Cl]Cl_2$ (purpureo chloride), are obtained. These compounds were discovered by F. A. Genth in 1847 and described in detail, together with related salts, in a monograph, "The Ammonia-Cobalt Bases," by F. A. Genth and Wolcott Gibbs, published by the Smithsonian Institution in Washington in 1856. By suitable variations in the procedure outlined above, the ammonia may be replaced by equivalents of ethylenediamine and other organic bases, and the chlorine by many other negative radicals. Hundreds of beautifully crystallized and highly coloured compounds have been produced, of which a few additional examples are: dichlorotetrammine cobaltichloride, $[Co(NH_3)_4Cl_2]Cl$, obtained in green (praseo) and violet (violeo) isomeric forms, dinitrotetrammine cobaltinitrate, $[Co(NH_3)_4(NO_2)_2]NO_3$, occuring as brown (flavo) and yellow (croceo) isomers, trinitrotriammine cobalt, $[Co(NH_3)_3(NO_2)_3]$, a nonelectrolyte (forming no ions in solution), and ammonium tetranitrodiammine cobaltiate, $NH_4[Co.(NO_2)_4(NH_3)_2]$, known as Erdmann's salt. A study of these compounds enabled Alfred Werner of Zürich, during the period 1893–1918, to formulate the well-known co-ordination theory, which has proved to be a powerful tool for dealing with many classes of inorganic compounds. He pointed out that in all of the cobaltammines, six molecules or radicals, or their equivalents are attached directly to, or "co-ordinated" with the central cobalt atom, forming a unit, now often called a Werner complex. This unit may exist as an ion in solution. The co-ordination number of cobalt is said to be six. He further showed that the resulting molecule is not planar but three-dimensional: the cobalt atom being at the centre of an octahedron, with its valencies directed to the six corners, where the co-ordinated groups are located. The validity of this con-

ception was established, experimentally, by chemical reactions involving structural isomers, and finally by the preparation of optically active co-ordination compounds of cobalt. Examination of many co-ordination compounds by X-rays has fully confirmed these views, so that the octahedron is as firmly established for inorganic compounds, where the co-ordination number is six, as is the tetrahedron in the chemistry of carbon. (*See* CO-ORDINATION COMPOUNDS.)

Analytical:—*Detection.*—The characteristic dry test for cobalt is the intense blue colour imparted to the borax bead by small quantities of salts or other compounds. In the regular course of qualitative analysis, cobalt and nickel are precipitated together as sulphides by ammonium sulphide. They may be separated by the cyanide method, which consists in dissolving the mixed sulphides in aqua regia, removing the excess of acid, and adding an excess of potassium cyanide to the neutral solution. The complex cyanides, $K_4[Co(CN)_6]$ and $K_2[N:(CN)_4]$, are formed, and on boiling their solution, the former is oxidized to the very stable cobalticyanide, $K_3[Co(CN)_6]$, leaving the nickel cyanide unchanged. Sodium hypobromite, NaBrO, is then added, precipitating black hydrated nickelic oxide, and leaving the cobalt in solution. The filtrate from the insoluble nickelic oxide may be evaporated to dryness, and the residue tested for cobalt in the borax bead.



Estimation.—In compounds containing no nonvolatile constituent, cobalt may be determined accurately and rapidly by evaporation with a few drops of concentrated sulphuric acid, and weighing as the violet anhydrous sulphate, $CoSO_4$. Cobalt may also be estimated by electrolytic deposition on a platinum dish from an acid solution containing ammonium sulphate.

The quantitative separation of cobalt from nickel and certain other metals is best effected by precipitation with α-nitroso-β-naphthol from acid solution. The bulky, purplish red precipitate,

is ignited to Co_3O_4, and weighed as such, or the oxide may be reduced by hydrogen to metal.

An accurate and rapid colourimetric method for the determination of cobalt in dilute solution (0.015 g. $CoSO_4$ per 1 litre) is based on the formation of a soluble red complex with nitroso-R-salt,

Small amounts of nickel and iron do not interfere.

COBALTITE, a mineral with the composition CoAsS, cobalt sulpharsenide. It is found as granular to compact masses, and frequently as beautifully developed crystals, which have the same symmetry as the isomorphous mineral pyrite, being cubic with parallel hemihedrism. The usual form is a pentagonal-dodecahedron with faces of the cube and octahedron. The colour is silver-white with a reddish tinge, and the lustre brilliant and metallic, hence the old name cobalt-glance. The brilliant crystals from Tunaberg in Sodermanland, Sweden, and from Skutterud near Drammen in Norway are well known in mineral collections. Crystals have also been found at Khetri in Rajputana, and under the name *sehta* the mineral is used by Indian jewellers for producing a blue enamel on gold and silver ornaments.

COBÁN, a city of Guatemala, Central America, capital of the department of Alta Verapaz and the northern centre of the coffee trade. Population (1950) 7,917. Cobán is 105 mi. north of Guatemala City, although overland connections (motor to El Rancho, thence by rail) are rather poor. Principal commercial outlet of the district is via the Polochic river, Lake Izabal and the Río Dulce to the Caribbean port of Livingston. Besides being a rich area in the production of coffee, there are numerous plantations of tea, cacao, vanilla, etc., surrounding the city.

COBB, HOWELL (1815–1868), American political leader, was born at Cherry Hill, Ga., on Sept. 7, 1815. He graduated from Franklin college (University of Georgia) in 1834, and in 1836 was admitted to the bar. From 1837 to 1840 he was solicitor-general for the western circuit of his State. In 1843–51 and in 1855–57 he was a member of the national House of Representatives, becoming Democratic leader in that body in 1847, and serving as speaker in 1849–51. From 1851 to 1853 he was governor of his State; and from 1857 to 1860 he was secretary of the Treasury in President Buchanan's cabinet. In 1861 he was appointed colonel of a regiment and two years later was made a major-general in the Confederate army. He sided with President Jackson on the question of nullification; was an efficient supporter of President Polk's administration during the Mexican War; and was an ardent advocate of slavery extension into the Territories, but when the Compromise of 1850 had been agreed upon he became its staunch supporter as a Union Democrat, and on that issue was elected governor of Georgia by a large majority. In 1860, however, he ceased to be a Unionist, and became a leader of the secession movement. He died in New York city on Oct. 9, 1868.

See W. B. Phelps (ed.), "The Correspondence of Robert Toombs, Alexander H. Stephens and Howell Cobb," *Am. Hist. Assoc., Annual Report*, vol. ii. (1911).

COBB, IRVIN SHREWSBURY (1876–1944), U.S. author and journalist, was born in Paducah, Ky., on June 23, 1876. He left school at an early age to begin his career in journalism as a reporter and cartoonist for the local newspapers. He was managing editor of a newspaper, the *Paducah Daily News*, at the age of 19.

In 1904 he became a writer and editor for the *New York Evening Sun*, and from 1905 to 1911 was staff writer for Joseph Pulitzer's *New York Evening World* and *New York Sunday World*. He rapidly became widely known as a writer with humorous and ironical insight.

Cobb wrote for national magazines, lectured throughout the United States, and acted in motion pictures. He also wrote many books and plays, both serious and humorous. He died March 10, 1944.

COBBE, FRANCES POWER (1822–1904), British social writer and author, was born in Dublin on Dec. 4, 1822. Her first book, *The Theory of Intuitive Morals*, was published anonymously. In 1858 she began social work among the girls and boys of Bristol. She carried out various special investigations on vivisection, of which she was all her life a violent opponent, on destitution, and on separation orders and divorce. She was a strong suffragist. From time to time she conducted services in Unitarian chapels.

She published about 30 separate works, among which may be mentioned: *Essay on Intuitive Morals* (1855), *Pursuits of Women* (1863), *Hours of Work and Play* (1867), *Dawning Lights* (1868), *Darwinism and Morals* (1872), *The Hopes of the Human Race* (1874), *The Duties of Women* (1881), her own *Life* (2 vol., 1894), and *The Scientific Spirit of the Age* (1888).

COBBETT, WILLIAM (1763–1835), English author, journalist and Radical, is one of the most representative figures in English literature, and his life and writings embody the history of the common people between the revolutions of the eighteenth century and the dawn of the Victorian era. He was born at Farnham, Surrey, on March 9, 1763 (not 1766, as he himself wrongly stated). His father was a small farmer; and his grandfather had been a day-labourer. As a boy, he worked in the fields, but, at 14, began his adventures by running away from home and getting work in Kew Gardens. He returned home after a while; but, at 19, after an unsuccessful attempt to join the Navy during a visit to Portsmouth, again left Farnham and, going to London on a sudden impulse, found employment as a solicitor's clerk.

Soon sickening of this occupation, he went down to Chatham, meaning to enlist in the Marines, but found himself in a line regiment instead. After a year at the depot, during which he read hard and discursively and taught himself grammar and writing, he was drafted, as corporal, to Nova Scotia, where his regiment was stationed. Soon, however, he was shifted to Fredericton, New Brunswick, where he remained till 1791, rising rapidly to the position of regimental sergeant-major. This position made him conscious of the systematic fraud and peculation which went on in the regiment—as indeed throughout the service—and he set to work to collect evidence against the principal offenders. At length, in 1791, his regiment was ordered home; and he at once procured his discharge, with excellent testimonials. Having done this, he immediately set about bringing the defaulters to book, and demanded a court-martial of the officers against whom he had collected evidence. This was at length granted; but Cobbett was unable to secure the discharge of his essential witness, or to get the regimental books impounded for safekeeping. In despair of getting the case fairly heard, he failed to appear at the court-martial, and fled to France in March 1792. He had married Ann Reid, to whom he had become engaged some years before in New Brunswick, while he was awaiting the court-martial proceedings; and she joined him in France. He remained there until the late summer of 1792 when, seeing the outbreak of war to be imminent, he took ship for America. There, first at Wilmington and later at Philadelphia, he supported himself by teaching English to the French *émigrés*, who were reaching the United States in large numbers.

So far Cobbett had written little. In the army, he had composed a grammar for the use of private soldiers; but this was not published. He had also almost certainly a hand in a pamphlet exposing army abuses, published in 1793 under the title of *The Soldier's Friend*. But in 1794 occurred an incident which really embarked him on his long career as a political writer. Joseph Priestley, the great Unitarian Radical, came in that year to settle in the United States, and numerous addresses of welcome were presented to him by American Radical societies. These aroused Cobbett's strong pugnacious instincts; and he entered the lists as a pamphleteer with his *Observations on Dr. Priestley's Emigration* (1794). From that date until his return to England in 1800, he was the most vehement and violent writer on the British side in the United States, producing a series of tirades against the French Revolution and all its works, and against all Americans who ventured to give it, or any sort of Radicalism, even the mildest support. *A Bone to Gnaw for the Democrats, A Kick for a Bite, The Scare-Crow, The Cannibal's Progress* (an account of the horror of the French Revolution), and a scurrilous *Life of Tom Paine*, are among these early pamphlets. They are all unmeasured in violence, and often outrageous, but always lively, readable and written in really virile and forthright English. Cobbett's style was almost as good in his first unpracticed writings as in the best of his more famous later work. Pre-eminent among these early pamphlets is his autobiographical *Life and Adventures* of Peter Porcupine (the highly apposite name under which he had chosen to write) in which he defended himself against those who abused him by an account of his upbringing and early career. This pamphlet is one of the best of all his writings. He also supplemented his pamphleteering with a regular newspaper, *Porcupine's Gazette*.

Cobbett was soon in trouble with the law. He libelled Dr. Rush, doctor and well-known Democratic politician, accusing him of killing George Washington with his special "bleeding treatment." This brought a heavy fine, and he then wrote scurrilous pamphlets about McKean, the judge who had tried the case, and was Rush's political ally. Before long he made the United States too hot to hold him, and in 1800 he gave up the contest and returned to England, where his writings, regularly republished, had already made him well known. He was greeted with enthusiasm as a powerful recruit to jingo journalism. He met Pitt at dinner, and was offered the editorship and ownership of one of the leading Government newspapers. He refused the offer, as he had already refused Government payment for his services in America, and attempted instead to start a daily newspaper of his own, *The Porcupine*. This speedily failed; but in 1802, with help from Dr. Laurence and William Windham, who was for some years his chief political supporter, he started the weekly *Political Register*, which he thereafter edited, and for the most part wrote, regularly until his death in 1835.

The *Political Register*, with which Cobbett's name was always from 1802 chiefly associated, began its career as an extreme anti-Jacobin journal. It strongly opposed Addington and the Peace of Amiens, and called loudly for a renewal of the war with France. But after Pitt's return to power and the renewal of the war, Cobbett slipped gradually into opposition, and found himself in alliance with Windham and with Fox, the latter of whom he had hitherto vehemently denounced. In 1806, in the Ministry of All the Talents, his friends came to power; but Cobbett soon fell into opposition to them also. He was by this time denouncing the "Pitt system" as the root of all evil, and attacking in particular the methods of pursuing the war, the multiplication of pensions and sinecures, and the dangerous growth of the National Debt. When the Ministry of All the Talents broke up in 1807, he was already definitely a Radical, at war equally with Whig and Tory, and beginning to cry out for peace and parliamentary reform as well as for "economical reform."

So far, Cobbett was merely an outstanding political journalist, whose writings, however trenchant, had given little indication of his peculiar quality as a democratic leader. But from about 1805 a new tone begins to appear in his work. From 1800 to 1805 he had lived in London; but in the latter year he bought a substantial farm at Botley, near Southampton, and spent most of his time in the country. The change opened his eyes to the great contrast between the countryside as he remembered it in his boyhood and as it had become under stress of war-time prices and enclosure. He realized for the first time the misery of the labouring classes, the effects of the Speenhamland system of poor relief, of the enclosure movement, of the great revolution in agrarian conditions that was then at its height. It roused his indignation —the indignation of one who was himself by nature and nurture a yeoman. It completed his conversion to Radicalism, which he expressed as the cause of the dispossessed and suffering labourers of rural England.

Cobbett, the one articulate voice among the suffering people of the countryside, brought a new note into Radical agitation. At once, he became a power. But his power brought penalties. In 1809 there was a minor mutiny among the soldiers at Ely, over unfair deductions from pay. The mutiny was suppressed, and the ringleaders were flogged under the eyes of German mercenaries. Cobbett wrote, denouncing the floggings, and was prosecuted for sedition. A fine of £1,000, two years in Newgate gaol, bail in £3,000 and the finding of two sureties at £1,000 each, were his punishment.

From Newgate, under the lax prison discipline of the time, Cobbett continued to edit the *Register*, and wrote his famous *Paper against Gold*, in which he denounced the war-time inflation of the currency, and the financial policy of Pitt and his successors. His imprisonment, however, brought him financial ruin. He went bankrupt. His farm at Botley was sold; and most of his valuable properties passed out of his hands. The *Register* he barely saved. Three great publishing enterprises on which he was engaged had to be sold—the *State Trials* (known as Howell's, from the editor whom Cobbett employed), the *Parliamentary History of England*, and the *Parliamentary Debates*, which were bought by his printer, Hansard, and thereafter bore the latter's name. All these were originated by Cobbett, though the actual editorship, under his control, had been mainly left to others.

When Cobbett emerged from prison in 1812, he appeared to be ruined. But he had still the *Register*, and the ending of the war, in 1815, brought him his chance. Prices fell, indeed; but the cessation of war demand and the prostration of Europe after the long struggle led to widespread unemployment and distress. In the industrial districts, unrest grew; and the farmers, pressed down by high taxation, were also in a condition of active discontent. The Government had no plans for dealing with the crisis;

and Cobbett with his demands for parliamentary reform and a reduction of the heavy interest on the National Debt, became the central figure in a nation-wide agitation. In 1816, he began the issue of a cheap unstamped *Register* (denounced as Cobbett's "two-penny trash") addressed particularly to the journeymen and labourers of the Northern and Midland counties. He became suddenly the most influential leader of the working classes. But by this time the Government, alarmed at hunger-riots and movements of despair and discontent, was embarking on a campaign of repression which recalled Pitt's measures in the years following the French Revolution. In 1817 Lord Sidmouth, the Home Secretary, passed his "Gagging Bills" and procured the suspension of the Habeas Corpus Act. Widespread arrests of Radical leaders followed; and Cobbett, in order to avoid arrest, fled to the United States, where he remained until 1819.

Settling down on a hired farm at North Hempstead, Long Island, Cobbett set himself to write. He sent the copy regularly for the *Political Register,* which continued to be published by his agents in England. But he also embarked on other literary work. To the respite which exile gave him from daily political preoccupations we owe the beginning of his great literary period. Hitherto he had written much excellent journalism, but no important book. But between 1817 and 1819 he produced not only his *Journal of a Year's Residence in the United States of America,* but also his famous *Grammar of the English Language,* which, despite its faults of scholarship, is still probably the best introduction to correct virile English for the working-class student. In America, too, he projected certain others of the important books which he produced, from this time onwards, with profuse mental vigour.

Although the repression was by no means over—indeed, the "Six Acts" were not passed until after his return—Cobbett came back to England late in 1819, and assumed his place as the outstanding leader of working-class radical agitation. From 1819 to 1832 his history is, in one aspect, the history of the agitation for parliamentary reform. But he found scope for other activities as well, above all for his well-known *Rural Rides* through the southern half of England. His accounts of these appeared in the *Register* between 1820 and 1830, in which year they were first published in book form.

Rural Rides, certainly Cobbett's best widely read book except the *Grammar,* are difficult to describe. They are, in part, a plain account of what he saw in the English countryside—of good farming and of bad, of rotten boroughs and the country houses of bankers, stock-jobbers and successful army contractors, and above all of the misery and starvation of the common people. But they are far more than this. They abound in digressions, in racy snatches of autobiography, in topical political tirades, and everywhere in abundant outflowings of Cobbett's own forceful and appealing personality. Though they were composed in haste and sent off to the *Register* without chance of revision, they were astonishingly well written. *Rural Rides* are Cobbett at his best, showing more sides of the man than appeared in any other of his works.

But *Rural Rides,* and the ceaseless "rustic harangues" which accompanied them, did not, even with the added burden of conducting the *Register* and actively guiding a large section of the reform movement, at all exhaust Cobbett's energies. Books, and mostly good books, flowed from him—*Cottage Economy* and the *Sermons* in 1822, *The History of the Protestant Reformation in England* (questionable history this, but vigorous writing) in 1824–26, *The Woodlands* in 1825, *Advice to Young Men* (next to *Rural Rides* his best book) and *The English Gardener* in 1829, and a host of others. Moreover, in 1820–21 he whole-heartedly espoused the cause of Queen Caroline against the king, acted as one of her regular advisers before the famous trial, and wrote ceaselessly on her behalf. He even composed a number of her own letters and messages concerned with the case. And in his hands the defence of the Queen became also a means of rallying the forces of the Reformers.

Meanwhile, in 1820, he had rid himself by bankruptcy of some of his financial worries, and had settled down to rebuild his shattered fortunes by means of his pen. Botley had been given up, and for awhile he had no land. But soon he developed a flourishing seed-farm in Kensington, and began to deal also in American trees, and in a variety of imported seeds and plants. Especially he urged the cultivation of maize ("Cobbett's corn"), of the locust tree, and of Swedish turnips, as well as the introduction of the straw-plait manufacture from home-grown grasses. His seed-farm and his agricultural writings brought him a large following among the farming classes.

In 1830, with the fall of Wellington and the end of the long period of Tory ascendancy, the reform agitation came to a head. The Whigs, under Lord Gray, assumed office, and reform became the one political question of the day. Immediately upon this change followed the hunger movement of the rural labourers in the southern and eastern counties, known as "the last labourer's revolt." The opponents of the movement sought to trace these troubles to Cobbett's influence, and the Whig Government, anxious to prove its respect for property and to reassure the propertied classes as the subject of reform, prosecuted him. Refusing to employ counsel, Cobbett defended himself in a masterly speech, which thoroughly turned the tables on his opponents. The jury disagreed, and no further attempt was made to molest him. The revolt, however, was savagely repressed.

At length, in 1832, the Reform Act became law. Cobbett, though he had no love for the Whigs, had urged the workers to support it, on the ground that no more liberal measure stood any chance of immediate success. At the election which followed he was elected M.P. for Oldham, as the colleague of John Fielden, the Radical manufacturer. He had stood at Manchester also, but withdrew on learning of his success at Oldham.

This was not Cobbett's first parliamentary contest. He had stood unsuccessfully for Coventry in 1820 and for Preston in 1826. Indeed, for many years he had been seeking to force his way into parliament. At sixty-eight years of age, he found himself a member, as strongly in opposition to the reformed parliament of 1832 as he could have been to the unreformed parliaments of earlier years. His two and a half years of parliamentary life he passed as the leader of a tiny group of extreme radicals, supported sometimes by O'Connell and his Irish, but always fighting for forlorn hopes. Especially, he put up an unavailing struggle against the "new poor law" of 1834, and his last weeks of life were spent in the endeavour to run a campaign against the act when it had been passed into law.

It is usually said that Cobbett was not a success as a parliamentarian. He could hardly have been so, for he accepted none of the rules of the game. He remained to the end the leader of an essentially extra-parliamentary crusade. But already his health was failing. He had been always an indefatigable worker, rising very early and doing a good part of a day's labour before other men were astir. Now severe colds and coughs began to trouble him; but he insisted on adding assiduous attention to his parliamentary duties to his other multifarious activities. In 1835 his health gave way under the strain, and, on June 18, he died of an attack of influenza. His sons attempted for a few months to carry on the *Register;* but it was nothing without his vigorous editorials, and was speedily discontinued.

Cobbett was survived by his wife and by seven children. Anne, the eldest (1795–1877), wrote *The English Housekeeper* and other works. Both she and the two other daughters, Eleanor and Susan, remained unmarried. The three eldest sons all went to the bar. William (1798–1878) wrote *The Law of Turnpikes* and other legal works, and edited the *Register* for a while after his father's death. John Morgan (1800–1877) wrote several books, stood unsuccessfully for Oldham in 1835, and successfully, as an Independent, in 1852. He held the seat till 1865, and again, as a Conservative, from 1872 to 1877. He married John Fielden's daughter in 1851. James Paul (1803–1881) wrote *A Ride in France, Journal of a Tour in Italy,* etc., and stood for Bury as a Radical in 1837. Richard Baverstock Brown, the youngest son (1814–1875) became a solicitor in Manchester, and was active there in the Chartist movement.

Cobbett's character has been variously estimated. He was

always extremely pugnacious, and made many enemies. But he made also many firm friends. His pugnacity, which led him to quarrel, almost as much with allies as opponents, was purely political. Carlyle called him "the pattern John Bull of his century"; his fellow M. P., Buckingham, said that he had "a ruddy countenance, a small laughing eye, and the figure of a respectable English farmer." Hazlitt, who liked his books, also said he looked like a farmer. Cobbett was, indeed, despite his appeal to the workers of the factory districts, always at heart a countryman, with an unconquerable instinct for the land and the men of the land. He was intensely English, and, in his way, intensely patriotic; and it was this patriotism that roused him to the defence of his fellow-countrymen, trodden under by the oppressions of war and the twin revolutions in agriculture and industry whose devastating social effects he watched from phase to phase. He was that rarest of literary portents—an articulate peasant. His prose is astonishingly quick in its movement, and yet solid as a lump of earth. His clods of abuse and denunciation stick to-day. He had a marvellous facility for nicknames, and for the ridicule that hurts. But above all his prose depends for its success on the personal quality that pervades it. It is spoken rather than written down; and in it the man lives. *Rural Rides* and *Advice to Young Men* will be read as long as English is read at all. Cobbett has often been called an egoist, and he was; but his egoism—his capacity to make himself express the aspirations of a whole suffering class—is at the very root of his appeal.

BIBLIOGRAPHY.—Most of Cobbett's important writings have been mentioned above. Besides a host of pamphlets, his other books include *Porcupine's Works* (selections from his early American writings, in 12 vols., 1801); *A Collection of Facts and Observations relative to the Peace with Bonaparte* (1801); *Letters to Addington, in the Fatal Effects of the Peace with Bonaparte* (1802); *Letters to Lord Hawkesbury, on the Peace* (1802); *The Political Proteus* (an attack on R. B. Sheridan, 1804); *Letters on the Late War between the United States and Great Britain* (1815); *The Pride of Britannia Humbled* (New York, 1815); *Paper against Gold* (1815); *The American Gardener* (1821); *Collective Commentaries* (1822); *French Grammar* (1824); *The Poor Man's Friend* (1826); *A Treatise on Cobbett's Corn* (1828); *The Emigrants' Guide* (1829); *History of the Regency and Reign of George IV.* (1830); *Lectures on the French and Belgian Revolutions* (1830); *Spelling Book* (1831); *Tour in Scotland* (continuing *Rural Rides*, 1832); *Manchester Lectures* (1832); *Geographical Dictionary* (1832); *French and English Dictionary* (1833); *Four Letters to the Hon. John Stuart Wortley* (1834); *Life of Andrew Jackson* (1834); *Lectures on the Political State of Ireland* (1834); *Legacy to Labourers* (1835); *Legacy to Parsons* (1835); *Legacy to Peel*, (1836). Six volumes of selections from the *Register*, under the title, *Cobbett's Political Works*, were published in 1835–36.

Of the lives, the most recent is by G. D. H. Cole (1924). There are other lives by Huish (1836), E. Smith (1878), E. I. Carlyle (1904), and Lewis Melville (1913). (G. D. H. C.)

COBBOLD, THOMAS SPENCER (1828–1886), English man of science, was born at Ipswich in 1828, a son of the Rev. Richard Cobbold (1797–1877), the author of the *History of Margaret Catchpole*. From 1868 he acted as Swiney lecturer on geology at the British Museum until 1873, when he became professor of botany at the Royal Veterinary college, afterwards filling a chair of helminthology which was specially created for him at that institution. He died in London on March 20, 1886. His special subject was helminthology, particularly the worms parasitic in man and animals. His numerous writings include *Entozoa* (1864); *Tapeworms* (1866); *Parasites* (1879); *Human Parasites* (1882); and *Parasites of Meat and Prepared Flesh Food* (1884).

COBDEN, RICHARD (1804–1865), English statesman and economist, was born at Dunford Farm, near Midhurst, Sussex, the son of a small farmer, who died when Richard was a child. There were 11 children, who were befriended by relatives. Richard was sent to one of the bad private boarding schools of those days, in Yorkshire, and in 1819 became a clerk in his uncle's warehouse in Old Change, London. After serving in the warehouse he began to travel for the firm. In 1828 he joined with two friends in setting up business as calico merchants. Three years later the firm acquired a factory at Sabden, Lancs., and began to do their own calico-printing. This was the beginning of a business career which brought Cobden an independent fortune and permitted him in later years to devote himself, untrammelled by financial difficulties, to his life work for greater freedom of trade. He remedied his lack of education by a course of serious study and by travel in the United States (June–Aug. 1835) and in the Near East (1836–37), in Germany (1838) and elsewhere, making full use of his opportunities of studying the economic and financial systems of the countries he visited. At this time he published two pamphlets which show that the broad lines of his ideas on foreign policy were already matured. These are *England, Ireland and America* (1835), by "a Manchester Merchant," in which he maintained that England had no interest in defending Turkey against Russia; and *Russia* (1836), in which he attacks the doctrine of the balance of power.

In October 1838 a group of seven Manchester merchants met to form an association to promote a movement for the abolition of the corn laws (*q.v.*). This became the nucleus of a national association, the Anti-Corn-Law league. From the beginning Cobden was the moving spirit in the league. Though other great names were associated with it, Cobden's was the directing mind. He had already met John Bright in connection with a campaign for providing education for the mass of the people, and had drawn him into politics. Bright's eloquence moved thousands in the meetings organized by the league, but Cobden's counsels carried more weight among statesmen. Throughout the whole of this campaign Cobden linked up the question of free trade with that of peace and disarmament; he regarded liberty of commerce as a key to international solidarity. He entered the House of Commons for Stockport at the general election of 1841. Parliament met in August, and Sir Robert Peel moved a vote of censure on the Whig Government, which was carried on Aug. 28. The new administration proposed a modification of the corn law which altered the sliding scale of 1828 and reduced the duty. Villiers' annual motion for repeal was defeated. Cobden presented his case against the corn law in his first speech in the House during the debate on the address. His sincerity and his precise knowledge of the question in hand made a strong impression. He proved a redoubtable opponent of Peel's financial policy, and persistently opposed the reintroduction of income tax.

Cobden desired the minimum of interference in trade and industry. When Graham's Factory Bill was brought forward in 1844 he accepted the regulation of child labour but he protested against any "interference with the freedom of adult labour." He was less extreme than Bright in his individualism, but had no use for the early reformers of the terrible factory system of the day, because he would not accept the principle of Government intervention. On the other hand he ardently supported measures for the improvement of education, and supported Peel's proposal to augment the grant to the Irish Roman Catholic college at Maynooth, on the ground that the priests were the instructors of the people and should themselves be thoroughly educated.

Meanwhile Cobden worked incessantly for the Anti-Corn-Law league, speaking all over the country, and, with increasing force in the House of Commons itself. His most powerful speech was perhaps that made in the House on March 13, 1845, when Peel, who was expected to reply, is said to have crumpled up his paper and notes and said to Sidney Herbert, "You may answer this, for I cannot." Some members of the Peel Government had realized at the time of Peel's first budget that the next change in the corn laws must be their total repeal. The prospect of famine in Ireland at the end of the year made the change inevitable. On Dec. 5 Peel resigned. Lord John Russell, invited to form a cabinet, asked Cobden to take office, but he declined on the ground that his mission lay outside the House on the public platform. On the 20th Peel resumed office. For the course of the events in the session of 1846 *see* PEEL, SIR ROBERT. It is sufficient here to say that Peel's famous resolutions included a modified sliding scale of duties for three years, and that after Feb. 1, 1849, oats, barley and wheat should be admitted at a nominal duty of a shilling. The bill embodying this resolution was passed by the House of Lords on June 25, 1846. Four days later Peel resigned, not without a tribute to Cobden. "The name," he said, "which ought to be, and will be, associated with the success of these measures, is not mine, or that of the noble lord (Russell), but the name of one who,

acting I believe from pure and disinterested motives, has, with untiring energy, made appeals to our reason, and has enforced those appeals with an eloquence the more to be admired because it was unaffected and unadorned: the name which ought to be associated with the success of these measures is the name of Richard Cobden."

The seven years' struggle for repeal left Cobden a ruined man, for he had been compelled to neglect his own business. A subscription was raised for him to enable him to meet his obligations. With part of the amount provided he bought his birthplace, the farmhouse of Dunford, which was thenceforward his home. He spent 14 months abroad (Aug. 1846–Oct. 1847), visiting the chief countries of Europe and urging on the many public men by whom he was received the necessity of greater freedom of trade. He returned more than ever opposed to a policy of intervention in any shape or form in the political situation of Europe. He now turned to work for the promotion of peace and the reduction of armaments, the logical complement of free trade, and became a formidable opponent of Palmerston's general foreign policy. In the parliament elected in 1847 he sat for the West Riding of Yorkshire. In that parliament he brought forward two important motions: one in favour of international arbitration (June 12, 1849), the other the mutual reduction of armaments (1851). He associated himself with the peace movement, at that time derided, and helped to organize a series of international congresses for the promotion of peace at Brussels, Paris, Frankfurt, London, Manchester and Edinburgh between 1848 and 1851. The panic which took possession of a large section of Englishmen in 1851 on the foundation of the Second Empire in France put his principles to the test. By his resolute campaign against the scaremongers in his pamphlet *1792 and 1853, in Three Letters* (1853), Cobden sacrificed the popularity he had won as the man who gave cheap food to the people. With Bright he withstood the torrent of popular sentiment in favour of war against Russia during the period before the Crimean War. He maintained strongly that the future of the Turkish provinces in Europe lay with the Christian populations and that England should be on their side and not on the side of the Turk. On Feb. 26, 1857, over the "Arrow" incident (Oct. 1856) in China, when Canton was bombarded on the ground that the Chinese had unlawfully boarded a ship of that name, Cobden brought in a motion condemning the action of Sir John Bowring in this matter, which was carried and led Palmerston to dissolve parliament. Cobden's peace policy had destroyed his electoral prospects. He was defeated at Huddersfield, and retired to his house in Sussex for the time; he then made a second visit to America.

On his return (June 29, 1859) he found he had been returned unopposed by Rochdale to the new parliament and that the Whigs were once more united under Palmerston, who asked him to join his cabinet as president of the board of trade. This offer, generous from a man of whose policy he had been the stoutest opponent, was declined on the ground that consistency forbade it. Nevertheless Cobden was the organizer of one important achievement of the new ministry, the conclusion of the commercial treaty with France of 1860. He first discussed the feasibility of such a proposal with Gladstone and then with Palmerston and Russell; from the two latter he received tepid encouragement, but was offered the assistance of the Paris embassy. He proposed to go to France to interview Napoleon III, and, in fact, spent a year (Oct. 1859–Nov. 1860) in laborious and at first unofficial negotiations (he only received definite official powers in Jan. 1860) for a mutual reduction of tariffs in the interest of increased trade between France and England. His work for the conclusion of this commercial treaty is proof, if any were needed, that Cobden was not a merely negative advocate of a *laissez-faire* policy, but a practical and constructive statesman.

The last of the greater issues of policy in which Cobden was involved was the American Civil War. He had been a regular correspondent of Charles Sumner's since 1851, and though his hatred of war made him say frankly that he would not have gone to war for emancipation, he did, after some hesitation, declare for the North, and J. A. Hobson, writing of this correspondence, asserts that he "did more than any other Englishman, save Bright, to correct the mistakes of fact and judgment which confused the issue in this country (Great Britian) at the outset, and to give sound counsel upon the sharp concrete cases which more than once brought us near to the breaking-point with the Federal Government."

Cobden died on April 2, 1865, in London after a journey which he had insisted on taking in order to be present at a discussion on a scheme of Canadian fortification.

His distrust of government at home and his limited belief in democracy were coupled with a firm belief in the good sense and worth of the middle classes. Starting from the belief that it was impossible to regulate wages by national considerations alone in industries competing in a world market, he regarded trade unionism as an unjustifiable use of monopoly. He was a child of the industrial revolution, and he believed that the removal of restrictions on the free play of self-interest would bring to everyone his due share of the profits of industry. He opposed factory legislation for this reason, except in the case of children, for whom he realized that freedom of contract was in fact freedom of coercion. Nevertheless in his later years his confidence in the beneficial results of middle-class domination began to be shaken, and the man who had written in 1842 (in a letter to F. W. Cobden) that trade unions were "founded upon principles of brutal tyranny and monopoly" wrote to William Hargreave in 1861, "Have they (the working people) no Spartacus among them to lead a revolt of the slave class against their political tormentors? . . . It is certain that so long as five millions of men are silent under their disabilities it is quite impossible for a few middle class members of parliament to give them liberty." But he was still thinking of the political rather than the industrial machine.

Cobdenism and what is called the Manchester school have fallen into some disrepute for various reasons, and in the criticisms launched on the school there is some danger of losing sight of the great services that Cobden rendered. His views on domestic and foreign policy were closely linked together. His experience convinced him that government intervention in the affairs of foreign countries was nearly always bad; he believed in the minimum of government at home and the minimum of intervention abroad. The subsequent controversy, still unsettled, was whether a too "spirited" or a too "passive" foreign policy would lead to the worse results. In the matter of international freedom of trade he was too optimistic. He believed that other countries would follow the English logic. He did not foresee the almost universal strength of economic nationalism, the enormous change in the whole structure of the economic world since brought about by gigantic foreign investments, with the development of new countries by the wealthier nations; he did not foresee the international operation of capital. But in his advocacy of arbitration, disarmament and peace he was far in advance of his time, and his ideals, apart from questions of practical application in circumstances as then existing, are justified by enlightened opinion today.

See his *Speeches*, ed. by John Bright and J. E. Thorold Rogers (1870); *Political Writings of Richard Cobden*, with introduction by Sir L. Mallet (1878); W. Bagehot, *Biographical Studies* (1881); John Morley, *Life of Richard Cobden* (1882); J. A. Hobson, *Richard Cobden* (1918), which contains Cobden's letters to Sumner, taken from the Sumner-Cobden correspondence preserved at Harvard.

COBERGHER, WENSEL (1557/61–1634), Flemish painter and architect, was born in Antwerp and died in Brussels. A prominent master of Flemish Baroque, he received his education as a painter in the workshop of Maarten de Vos and travelled in France and in Italy. He painted altarpieces for churches in Italy and in Belgium, but his pictures are far less important than his few surviving buildings. Of these the most famous is the church of Notre Dame de Montaigu (Flemish Scherpenheuvel), near Antwerp (1609). Of his other buildings the church of St. Augustine at Antwerp (1615) and the town hall at Ath are outstanding examples of Flemish Baroque. From 1605 until his death Cobergher was architect to the archduke Albert and the infanta Isabella, governors of the Spanish Netherlands. He wrote also on archaeology.

See J. H. Plantenga, *L'Architecture religieuse de l'ancien duché de Brabant au 17me siècle* (The Hague, 1926); P. Parent, *L'Architecture des Pays-Bas méridionaux aux 16me, 17me et 18me siècles* (Brussels, 1926). (A. NH.)

COBET, CAREL GABRIEL (1813–1889), Dutch classical scholar, was born at Paris on Nov. 28, 1813. After travelling in Italy to study Greek manuscripts, he was professor at Leyden (1846–84). He died on Oct. 26, 1889. Cobet's special weapon as a critic was his consummate knowledge of palaeography, combined with rare acumen and wide knowledge of classical literature.

His works include: *Prosopographia Xenophontea* (1836); *Observationes criticae in Platonis comici reliquias* (1840); *De Arte interpretandi Grammatices et Critices Fundamentis innixa* (1846), his inaugural address at Leyden; *Commentationes Philologicae* (1850–51); *Variae Lectiones* (1854); *Novae Lectiones* (1858); *Miscellanea Critica* (1876); *Collectanea Critica* (1878); observations of Dionysius Halicarnassensis (1877); professorial discourses (1852–60); and editions of *Diogenes Laertius* (1850), Philostratus *περὶ γυμναστικῆς* (1859), speeches of Hypereides (1858–77) and Lysias (1863). He was the editor of *Mnemosyne*.

See an appreciative obituary notice by W. G. Rutherford in the

Classical Review, Dec. 1889; Sandys *Hist. Class. Schol.* (1908) lii. 282.

COBH, a seaport, watering place and naval station of Co. Cork, Ire., on the south side of Great Island, on a hill above Cork harbour; formerly called Queenstown. Pop. (1951) 5,711. Until the end of the 18th century, Cove of Cork was a small fishing village. Its prominence is due to the fact that it became a military and naval centre and port of embarkation for troops. The quays are exposed to the south and south-east winds. The depth at the harbour entrance is 41 ft. (low-water) while in the river it is 29 ft. at high tides and 26 ft. at low tides. Vessels of 27 ft. draught have discharged at Cork deep-water quays lying afloat at all states of the tide. There is a large dockyard and victualling station at Haulbowline.

COBHAM, a village of Kent, England, 4 mi. W. of Rochester. Population of civil parish 933. The church (Early English and later restored) is rich in ancient brasses (1320–1529), commemorating thirteen members of the Brooke and Cobham families. Cobham college, containing 20 almshouses, after the dissolution took the place of a college for priests, founded by Sir John de Cobham in the 14th century. Cobham hall is mainly Elizabethan. The Cobham family was established here before the reign of King John. In 1313 Henry de Cobham was created Baron Cobham. In 1603 Henry Brooke, Lord Cobham, was attainted for participation in the Raleigh conspiracy, and died in prison in 1618. The attainder was reversed in 1916 and Dr. Gervase Alexander was summoned to parliament as Lord Cobham. There are, however, two Lords Cobham, for during the attainder of the barony Sir Richard Temple was created Baron and Viscount Cobham in 1718. Cobham hall was granted to Lodowick Stewart, duke of Lennox, and came by descent and marriage to the earls of Darnley.

COBIA or **CRAB-EATER** (*Rachycentron canadus*), a very voracious game-fish, cosmopolitan in warm seas, the only genus of the family Rachycentridae which, according to G. A. Boulenger, is allied with the mackerel-like fishes. The fish is slender and somewhat pike-like, reaching a length of five feet. The head is flattened and the lower jaw projecting. The tail is strong and forked, the upper lobe slightly the longer. The soft dorsal fin is long and low; in advance of it about eight low, isolated spines constitute the spinous dorsal. The anal is almost as long as the dorsal. This fish is dark olive green above, shading into lighter brownish-green and silvery. On the sides two distinct dark stripes parallel each other, one from tip of upper jaw to tail; the other starting at the origin of the pectoral fin. (*See* FISHES.)

COBLENZ or KOBLENZ, a city and fortress of Germany, in the Rhineland Palatinate, 57 mi. S.E. from Cologne by rail, situated on the left bank of the Rhine at its confluence with the Moselle, whence its ancient name *Confluentes*, of which Coblenz is a corruption. Pop. (1950) 66,444.

The town was one of the military posts established by Drusus about 9 B.C. Later it was frequently the residence of the Frankish kings, and in 860 and 922 was the scene of ecclesiastical synods. In 1018 the city, after receiving a charter, was given by the emperor Henry II. to the archbishop of Trier (Trèves), and it remained in the possession of the archbishop-electors till the close of the 18th century. In 1249–54 it was surrounded with new walls and it was partly to overawe the turbulent townsmen that successive archbishops built and strengthened the fortress of Ehrenbreitstein (*q.v.*) that dominates the city. As a member of the league of the Rhenish cities which took its rise in the 13th century, Coblenz attained to great prosperity. In 1344 the Moselle was spanned by a Gothic freestone bridge of 14 arches. The town suffered greatly, however, in the wars of the 17th, 18th and 19th centuries. In 1688 the French bombarded the Altstadt, destroying the old merchants' hall (*Kaufhaus*), which was restored in 1725. In 1786 the elector of Trier, Clement Wenceslaus of Saxony, took up his residence in the town, and a few years later it became one of the principal rendezvous of the French *émigrés*. In 1794 Coblenz was taken by the Revolutionary army and, after the peace of Lunéville, it was made the chief town of the Rhine and Moselle department (1798). In 1814 it was occupied by the Russians; by the congress of Vienna it was assigned to Prussia, and in 1822 it was made the seat of government of the Rhine province.

The city, down to 1890, consisted of the Altstadt (old city) and the Neustadt (new city), or Klemenstadt. The old city was triangular in shape, two sides being bounded by the Rhine and Moselle and the third by a line of fortifications. Here is the church of St. Castor, originally founded in 836 by Louis the Pious: the present Romanesque building was completed in 1208, the Gothic vaulted roof dating from 1498. In the old quarter, too, are the Liebfrauenkirche, a fine church (nave 1250, choir 1404–31) with late Romanesque towers; the castle of the electors of Trier, erected in 1280, which now contains the municipal picture gallery; and the family house of the Metternichs, where Prince Metternich, the Austrian statesman, was born in 1773. In the modern part of the town, the palace (Residenzschloss), built in 1778–1786 by Clement Wenceslaus, the last elector of Trier, contains some fine Gobelin tapestries. Coblenz is a principal seat of the Moselle and Rhenish wine trade. Its manufactures include pianos, paper, machinery, boats and barges, sugar, dyes and chemicals. It is an important transit centre for the Rhine railways and for the Rhine navigation. Immediately outside the former walls lies the central railway station, in which is effected a junction of the Cologne-Mainz railway with the strategical line Metz-Berlin.

Coblenz was bombed by the Allies in 1917 and 1918. After the Armistice the town and bridgehead were occupied by Allied troops under the Treaty of Versailles, the town forming the second zone to be evacuated after 10 years. (*See* RHINELAND.)

Coblenz was the seat of the Rhineland High Commission, and was occupied first by American troops and from 1923 to 1926 by French troops. In October 1923 Separatists proclaimed a Rhineland republic but in Feb. 1924 this movement collapsed.

Because of its importance as a railway centre, Coblenz was bombed by the British in World War II.

COBOURG, the capital of Northumberland county, Ont., Can., on Lake Ontario and the Canadian National and Canadian Pacific railways, 70 mi. E.N.E. of Toronto. Pop. (1951) 7,470. It has a large, safe harbour and steamboat connections with St. Lawrence and Lake Ontario ports. It is a centre for a rich dairy and fruit area; contains car works, foundries and carpet and woollen factories; and is a summer resort, especially for Americans. Victoria university, formerly situated there, was moved to Toronto in 1890.

COBRA, the name applied to the poisonous elapid snakes of the genera *Naja, Hemachates,* and *Ophiophagus,* which have the power of dilating the neck laterally to form a broad disc or "hood." The dilatation is brought about by the raising and pushing forward of the long anterior ribs, the elastic skin being stretched taut over this framework. This type of hood is in marked contrast to the vertical expansion of the neck of many snakes (*e.g.,* boomslang and mamba), which is caused by the inflation of the windpipe. In all species, however, erection of the hood only occurs when the animal is annoyed or disturbed.

The genus *Naja,* the cobras proper, containing about ten species, ranges from the Cape throughout Africa, Arabia and India to southern China, the Philippine Islands and the Malay archipelago; *Hemachates,* the spy slang of the Boers, with a single species, is confined to South Africa; *Ophiophagus,* the king cobra, ranges from Burma through the East Indies. These snakes are proteroglyphous, *i.e.,* with fixed poison fangs on the front of the upper jaw, and the bite of all the species is extremely dangerous. Accurate statistics of snake-bite mortality cannot be obtained, but it seems fairly certain that the common Indian cobra (*Naja naja*) is responsible for several thousand deaths annually.

As in all proteroglyphous snakes, the venom acts directly on the nervous system and so is much more rapid in its action than that of the viperine and opisthoglyphous snakes, the toxicity of which is chiefly because of the power of destroying the blood corpuscles. In the past, despite a multitude of so-called cures and a widespread belief in the efficacy of "snake stones," no really effective treatment was available except immediate excision of the site of the bite; now efficient "antivenines" are produced from the blood sera of animals that have been immunized by regulated

doses of venom. These antivenines, however, must be administered hypodermically. The dose is large and, to be effective for the bites of proteroglyphous snakes, must be given immediately, conditions not easily obtained in most of the regions which cobras inhabit. Danger to man is further enhanced by the fact that the prevalence of rats and mice frequently attracts cobras to the vicinity of villages and houses where they are more likely to come into contact with man. In India also, cobras are often regarded with so much superstitious reverence that no attempt is made to kill them.

THE COMMON COBRA OF INDIA (NAJA NAJA) SHOWING THE BOLD "SPECTACLE" MARKING OF THE HOOD

The best known species is the common Indian cobra (*Naja naja*), which may reach a length of about 5½ ft. and which exhibits great variation in colour; typically it is yellowish to dark brown with a black and white spectacle-shaped marking on the hood, but all gradations between this form and specimens without any trace of such a mark are known. The king cobra or hamadryad (*Ophiophagus hannah*) is another oriental species; it is rarer than the common cobra, larger, reaching a length of 12 ft. or more, and feeds chiefly on other snakes. Like all the cobras it lays eggs. It exercises some parental care; a definite nest of dried leaves is made and the parents remain in the vicinity of the nest until the eggs are hatched. There may be some care of the nest in the common cobra. In Africa there are several species, the hooded or Egyptian cobra (*Naja haje*) and the black-necked cobra (*Naja nigricollis*) being the most widely distributed. The latter species is able to spit its venom, like the spitting cobra or spy slang (*Hemachates haemachaetes*), which is closely allied to the true cobras and is notorious for its habit of "spitting" venom when annoyed. The mechanism of this "spitting" appears to be that by compression of the poison-glands the venom is forced out through the fangs to a distance of several feet and if it strikes an enemy in the eyes intense irritation is set up that results in temporary, and sometimes permanent blindness. In the accomplished venom spitters, the opening near the end of the fang faces directly forward, while in the cobras that spit only occasionally, like the common cobra, this condition is incipient.

(D. M. S. W.; X.)

COBURG, a town in Germany, in the *Land* of Bavaria, on the left bank of the Itz, 40 mi. S.S.E. of Gotha. Pop. (1950) 44,929. Coburg, first mentioned in a record of 1207, was of considerable importance in the 15th and 16th centuries, and owed its existence to the castle and to its position on the great trade route from Nürnberg via Bamberg to the north. In 1245 the castle became the seat of the elder branch of the counts of Henneberg (Coburg-Schmalkalden). The countships passed to Otto V. of Brandenburg, whose grandson sold them to Henry VIII. of Henneberg. The castle, town and countship then passed by marriage into the possession of the Saxon house of Wettin. In the 17th century the castle was strong enough to stand a three years' siege (1632–35) during the Thirty Years' War. In 1835 it became the residence of the dukes of Saxe-Coburg. The town contains many interesting buildings. The ducal palace, known as the Ehrenburg, originally erected on the site of a convent by Duke John Ernest in 1549, was renovated in 1698 and restored in 1816. It contains a decorated hall, the court church and a picture gallery. In the market square are the mediaeval *Rathaus* and the Government buildings. In the Schloss-platz is the Edinburgh palace, built in 1881. The educational establishments include a gymnasium, founded in 1604. The *Zeughaus* (armoury) contains the ducal library and among other public buildings may be mentioned the *Augustenstift,* formerly the seat of the ministerial offices, and the *Marstall* (royal mews). The castle was completely restored in 1835–38 and now contains a natural history museum. The most interesting room is that which was occupied by Luther in 1530. The chief manufactures are machinery, baskets, glass, colours and porcelain Iron-founding and saw-milling are also important, and there is trade in the cattle reared in the neighbourhood. For the princes of the house of Coburg *see* WETTIN; SAXE-COBURG-GOTHA.

COCA or **CUCA** (*Erythroxylon Coca*), a plant of the family Erythroxylaceae, the leaves of which are used as a stimulant in western South America. It resembles a blackthorn bush, and grows to a height of 8 feet. The branches are straight and the lively green leaves are thin, opaque, oval, more or less tapering at the extremities. A marked characteristic of the leaf is an areolated portion bounded by two longitudinal curved lines one on each side of the midrib, and more conspicuous on the under face of the leaf. Good samples of the dried leaves are uncurled, deep green on the upper, and grey-green on the lower surface, and have a strong tea-like odour; when chewed they produce a sense of warmth in the mouth, and have a pleasant, pungent taste. The flowers are small, and disposed in little clusters on short stalks; the corolla is composed of five yellowish-white petals, the anthers are heart-shaped, and the pistil consists of three carpels united to form a three-chambered ovary. The flowers are succeeded by red berries. The plants thrive best in hot, damp situations, such as the clearings of forests; but the leaves most preferred are obtained in drier localities, on the sides of hills. The leaves are considered ready for plucking when they break on being bent. The green leaves (*matu*) are spread in thin layers on coarse woollen cloths and dried in the sun; they are then packed in sacks, which, in order to preserve the quality must be kept from damp. The composition of different specimens of coca leaves is very inconstant. Besides the important alkaloid *cocaine* (*q.v.*) there are several other alkaloids. Coca leaves and preparations of them have no external action. Internally their action is similar to that of opium, though less narcotic.

COCAINE, one of a series of "cocaines," alkaloids (*q.v.*) occurring in the leaves of coca (*q.v.*), a shrub indigenous to Bolivia and Peru, but now chiefly produced by cultivation in Java.

Cocaine crystallizes from alcohol in colourless prisms, melting at 98° C.; it has a specific rotation $[\alpha]_D$ −15.8°, and it is readily soluble in ordinary solvents except water. It is generally used in medicine as the hydrochloride but sometimes as the base, dissolved or suspended in oils or fats. It yields well-crystallized salts of which the hydrochloride, $C_{17}H_{21}O_4N,HCl$, is the most important; this crystallizes from alcohol in short colourless prisms, melting at 200–202° C., and having a specific rotation $[\alpha]$ −67.5°. On hydrolysis with mineral acids or baryta, cocaine breaks up into *ecgonine* (tropine carboxylic acid), benzoic acid and methyl alcohol, so that cocaine is closely related to atropine (*q.v.*). It was synthetized in 1923 by Willstätter and Bode.

All the "cocaines" are found to be derivatives of a simple base, ecgonine, which contains both a hydroxyl (.OH) and a carboxyl (.COOH) group, the latter being esterified with methyl alcohol and the former with an acid group—benzoic acid in the case of cocaine, $C_{17}H_{21}O_4N$, and cinnamic or truxillic acid in the other natural "cocaines." In the process for the manufacture of cocaine the total alkaloids of Java coca leaves are hydrolysed to ecgonine, which is converted by esterification as described, so that most of the cocaine of commerce is a partially synthetic product.

Cocaine produces little or no action on the unbroken skin, but if it is injected subcutaneously, or applied to mucous membranes such as those of the mouth, eye or nose, anaesthesia of that area is produced so that slight operations can be carried out painlessly. A 5% or 10% solution is sufficient to abolish pain and touch, but stronger solutions are required to abolish sensations of heat and cold.

If cocaine is swallowed its anaesthetic properties act on the mucous membrane of the stomach; the sensation of hunger is deadened and, therefore, persons taking the drug by mouth can go for a long period without feeling the want of food. The central nervous system is first stimulated and later depressed, the higher centres being affected first. Moderate doses increase the bodily and mental power and give a sense of calmness and happiness; fatigue is abolished. Long, exhausting feats can be carried out under the greater bodily power produced, and the inhabitants of Peru chew the coca leaves for this reason. A single

large dose causes mental excitement, delirium, ataxy, with headache and depression later.

Therapeutically, cocaine is very largely used by oculists to produce anaesthesia of the eye; it is also used to relieve pain locally in other parts such as the mouth, teeth, ear, larynx, etc. A cocaine spray is often used to spray the throats of sensitive persons before making a laryngeal examination. It is too toxic to be used for infiltration or spinal anaesthesia.

It is practically never used for its stimulative effect. It is not a food. It is a dangerous drug and is habit forming. (*See* DRUG ADDICTION; NOVOCAIN.)

COCAMA (COQUAMILLA, UCAYALI), South American Indians living on the Marañón and lower Huallaga rivers, Peru, speaking a dialect of the Tupí-Guaraní stock. (J. H. SD.)

COCANADA (KAKINADA), capital of East Godavari district, Andhra state, India, on the coast in the extreme northeast of the Godavari delta, about 300 mi. N.N.E. of Madras. Pop. (1951) 99,952. Cocanada is the fourth port of southern India. The roadstead in Coringa bay is protected but shallow, so that steamers have to lie 7 mi. out, and the entrance to the canal, where the piers and wharves are situated, has to be constantly dredged. The town is connected by navigable channels with the canal system of the Godavari delta, and by a branch line with Samalkot on the Southern railway.

Cocanada's chief exports are rice, cotton and oilseeds. The industries include rice and oil mills, tile and saltworks and tobacco manufacture. The town contains the Pithapur Raja's college and the College of Engineering, both connected with Andhra university, Waltair.

COCCEIUS, the latinized name of Johannes Koch (1603–1669), Dutch theologian, who was born at Bremen on Aug. 9, 1603. After studying at Hamburg and Franeker, where Sixtinus Amama was one of his teachers, he taught at Bremen and at Franeker and in 1650 succeeded F. Spanheim the elder as professor of theology at Leyden. He died there on Nov. 4, 1669. His chief services as an oriental scholar were in the department of Hebrew philology and exegesis. As one of the leading exponents of the covenant or federal theology, he spiritualized the Hebrew scriptures to such an extent that it was said that Cocceius found Christ everywhere in the Old Testament and Hugo Grotius found him nowhere.

He taught that before the Fall, as much as after it, the relation between God and man was a covenant. The first covenant was a Covenant of Works. For this was substituted, after the Fall, the Covenant of Grace, to fulfil which the coming of Jesus Christ was necessary. Cocceius held millenarian views, and was the founder of a school of theologians who were called after him Cocceians. His most distinguished pupil was the celebrated Campeius Vitringa.

His most valuable work was his *Lexicon et Commentarius Sermonis Hebraici et Chaldaici* (Leyden, 1669), which has been frequently republished; his theology is fully expounded in his *Summa Doctrinae de Foedere et Testamento Dei* (1648). His collected works were published in 12 folio volumes (Amsterdam, 1673–75).

See Herzog-Hauck, *Realenzyklopädie.*

COCCIDIA: *see* PROTOZOA.

COCCULUS INDICUS, the commercial name for the dried fruits of *Anamirta cocculus* (family Menispermaceae), a large climbing shrub, native to India. It contains a bitter poisonous principle, picrotoxin, used in small doses to control the night sweats of tuberculosis.

Cocculus carolinus, the carolina moonseed of the same family, a trailing or climbing vine with broadly ovate, entire or lobed, deciduous leaves, greenish-white flowers in axillary and terminal racemes and red drupes occurs from Virginia and Kansas to Florida and Texas.

COCHABAMBA, a central department of Bolivia, occupying a series of fertile valleys on the eastern slope of the great Bolivian plateau, bounded on the north by the department of Beni, on the east by Santa Cruz, on the south by Chuquisaca and Potosí and on the west by Oruro and La Paz. Area, 21,479 sq.mi.; pop. (1950) 490,475.

Cochabamba's average elevation is about 8,000 ft., and its mean monthly temperature ranges from 50° to 71° F., making it one of the most agreeable climatic regions in South America. The rainfall is moderate (18 in. per year, coming almost entirely from November to March) and the seasons are marked by rainfall rather than by temperature.

Cochabamba is essentially an agricultural department, although its mineral resources are good and include deposits of gold, silver, copper and tungsten. Its temperate climate favours the production of wheat, Indian corn, barley and potatoes and most of the fruits and vegetables of the temperate zone. Coca, cacao, tobacco and most of the fruits and vegetables of the tropics are also produced.

Its forest products include rubber and cinchona. Lack of transportation facilities, however, has proved to be an obstacle to the development of any industry beyond local needs except those of cinchona and rubber.

The population is chiefly of the Indian and mestizo types, education is in a backward state, and there are few manufactures other than those of the domestic stage, the natives making many articles of wearing apparel and daily use in their own homes. Rough highways and mule paths are the usual means of communication, but Cochabamba (city) is connected by rail with Oruro (127 mi.) and Anani (37 mi.) and by motor road with La Paz (285 mi.). The capital is Cochabamba (*q.v.*); other important towns are Punata, Tarata, Totora, Cliza and Sacaba. (J. W. Mw.)

COCHABAMBA, a city of Bolivia, capital of the department of the same name and of the province of Cercado, situated on the Rocha, a small tributary of the Guapay river. Population (1950) 80,795, mostly Indians and mestizos. The city stands in a broad valley of the Bolivian plateau, 8,400 ft. above sea level, overshadowed by the snow-clad heights of Tunari, 127 mi. E.N.E. of Oruro, with which place it is connected by rail. The climate is mild and temperate and the surrounding country fertile and cultivated. The city is well supplied with foreign goods and enjoys a large part of the Amazon trade through some small river ports on tributaries of the Mamoré. It is also an important centre for air routes. A petroleum topping plant was completed in 1950, and the city is connected by pipeline (via Sucre) with the Camiri fields.

Cochabamba was founded in the 16th century and for a time was called Oropeza. It took an active part in the war of independence, the women distinguishing themselves in an attack on the Spanish camp in 1815, and some of them being put to death in 1818 by the Spanish forces.

In 1874 the city was seized and partly destroyed by Miguel Aguirre, but in general its isolated situation has been a protection against disorders. (J. W. Mw.)

COCHEM, a town of Germany, in the Rhineland-Palatinate on the Moselle, 30 mi. S.W. of Coblenz by rail. Pop. (1933) 5,459. It is situated at the foot of a hill with a feudal castle dating from 1051. The principal trade is in wines.

COCHERY, LOUIS ADOLPHE (1819–1900), French statesman, was born at Paris in 1819. After studying law he entered politics, and was on the staff of the ministry of justice after the revolution of Feb. 1848. From the coup d'état of 1851 to May 1869 he devoted himself to journalism. Then, elected deputy by the *département* of the Loiret, he joined the group of the left centre and was a supporter of the revolution of Sept. 4, 1870. His talent in finance won him a distinguished place in the chamber. From 1879 till 1885 he was minister of posts and telegraphs, and in Jan. 1888 he was elected to the senate. He died in 1900 in Paris.

His son, GEORGES CHARLES PAUL (1855–1914), also born in Paris, was in his father's department from 1879 till 1885, deputy from 1885, five times president of the Budget commission and minister of finance under (Felix) Jules Méline, premier from 1896 to 1898. Georges Cochery was vice-president of the chamber, 1898–1902, and again finance minister in the cabinet of Aristide Briand, 1909–10. He died in Paris in 1914.

COCHIN, DENYS MARIE PIERRE AUGUSTIN (1851–1922), French public official, was born at Paris in 1851. He

studied law, was elected to the chamber of deputies in 1893, and gradually became one of the leaders and principal orators of the conservative party.

He opposed the project of the income tax in 1894, the revision of the Dreyfus case in 1899 and the separation of the church and state in 1905.

His published works included *Le Monde extérieur* (1895); *Contre les barbares* (1899); and *Ententes et ruptures* (1905).

COCHIN, a former princely state (area: 1,493 sq.mi.; pop. [1941] 1,422,875) of southern India, which joined Travancore on July 1, 1949, to form the state of Travancore-Cochin (*q.v.*). Like Travancore, Cochin formed part of the ancient southern Indian kingdom of Kerala (*q.v.*). The accounts of the Aryan colonization of this area, to be found in the *Kerala Mahatmyam*, are conflicting. The Nambudri Brahmans appear to have established their supremacy over the indigenous tribes, but, because of internal dissensions, the Perumals were invited to administer the country. There is no definite historical evidence as to who they were or whence they came. Local Malabar chronicles assign Cheraman Perumal, the last of the Perumal rulers, to the 9th century A.D.

The period of Perumal rule is important as being the earliest period in Kerala history of which contemporary records, namely, the copperplate charters granted to the Jews and Christians, are extant. The modern state of Cochin occupied the centre of Kerala, and Ernakulam was the principal city.

The name Cochin does not seem to have been used until the end of the 15th century. The oldest name of the state was Perumpadappu, for Cochin was that part of Kerala which came into the possession of the eldest son of Cheraman Perumal's sister by Perumpadappu Nambudri. Because of this the rajahs of Cochin claim Perumal descent.

The connection between Cochin and the western world is very ancient. According to one tradition St. Thomas the Apostle first set foot in India at Malankara near Cranganur. Persecuted Jews also found a refuge there. The trade of the Malabar coast with the western world is more ancient still. (*See* E. H. Warmington, *The Commerce Between the Roman Empire and India,* Cambridge, New York, 1928). Little is known of the subsequent history of Cochin until the advent of the Portuguese. In 1498 Vasco da Gama reached the Malabar coast. At this time the cardinal factor in Malabari politics was the rivalry between the rajah of Cochin and the zamorin of Calicut. A knowledge of this, combined with the fact that the harbour of Cochin was greatly superior to that of Calicut as an anchorage, led the Portuguese to side with the rajahs of Cochin in their wars with the zamorin of Calicut. By the end of the 16th century Portuguese influence had become firmly established in Cochin. With the decline of Portuguese power in Indian waters the Dutch captured Cochin in 1663 and held it for nearly a century. In the second half of the 18th century Cochin was menaced by the growing Moslem power of Mysore. In 1776 Hyder Ali invaded Cochin and forced the rajah to acknowledge his suzerainty and pay him tribute.

In 1791 the rajah of Cochin entered into a subsidiary alliance with the English East India company, thus placing himself under English protection. In 1792, after the defeat of Tipu Sultan by Lord Cornwallis, the claims of Mysore over Cochin were transferred to the English company. In 1808 the chief minister of Cochin entered into a conspiracy with the minister of Travancore to assassinate the resident and oust the British. The insurrection was easily suppressed, and in 1809 a fresh treaty was concluded which increased the tribute and strengthened British control over the state.

In 1818 the financial obligations of Cochin were reduced to two lakhs of rupees. From this time the state greatly advanced in prosperity under successive rajahs. In 1862 the rajah received a sanad (charter) granting him the right of adoption on the failure of natural heirs. A series of longstanding disputes between Cochin and Travancore were settled by British arbitration in 1880. The Cochin state legislative council was inaugurated in 1925 and its powers enlarged in the years that followed. Public health, agriculture and cottage industries were transferred to the charge of an elected minister in 1938. An additional minister was appointed in 1946.

Under British paramountcy Cochin was controlled (from 1923) through the Madras states agency (Trivandrum residency).

(C. C. D.)

COCHIN (KOCHCHIBAND), a port on the Malabar coast of India, 580 mi. S. of Bombay and 125 mi. W. of Madura; situated politically in an enclave of Malabar district, Madras state, surrounded by the state of Travancore-Cochin. The contiguous town of Mattancheri (pop., 1951, 73,904) is in Travancore-Cochin. Cochin (pop., 1951, 29,881) is at the northern end of a tongue of land about 12 mi. long but in few places more than a mile wide, nearly isolated from the mainland by inlets and estuaries. These form the Cochin backwaters, shallow lagoons lying behind the beach line and below its level, which are broad navigable channels and lakes during the monsoon, but in many places not two feet deep in the hot weather.

Cochin was the earliest European settlement in India, the first occupants being the Portuguese. Vasco da Gama founded a factory in 1502, and Alphonso d'Albuquerque built a fort, the first European fort in India, in 1503. The British made a settlement in 1634, but retired when the Dutch captured the town in 1663. Under the Dutch the town became a great trading centre. In 1795 Cochin was captured from the Dutch by the British, and in 1806 the fortifications and many buildings were blown up by order of the authorities.

The construction of the modern harbour began in 1920. In this the British government collaborated with those of the then princely states of Cochin and Travancore. In June 1928 the first ocean-going steamer entered the harbour. The improvements made thereafter, and its geographical position, make Cochin an ideal distributing centre. It is open for deep-water traffic in the worst monsoon. The Cochin Harbour railway is connected with the broad-gauge system of the Southern railway. The port administration was wholly taken over by the Indian government on Aug. 1, 1936.

COCHIN CHINA: *see* INDOCHINA; VIETNAM.

COCHINEAL, a natural dyestuff used for the production of scarlet, crimson, orange and other tints, and for the preparation of lake and carmine. It consists of the females of *Dactylopius coccus,* an insect of the family Coccidae of the order Hemiptera, which feeds upon various species of Cactaceae, especially nopal, *Opuntia coccinellifera,* a native of Mexico and Peru.

The dye was introduced into Europe from Mexico, where it had been used long before the entrance of the Spaniards. Cochineal has almost entirely been replaced by aniline dyes. The male of the cochinal insect is half the size of the female, and, unlike it, is devoid of nutritive apparatus; it has long white wings and a body of a deep red colour, terminated by two diverging setae. The female is wingless, and has a dark-brown plano-convex body; it is found in the proportion of 150–200 to 1 of the male insect. The dead body of the mother insect serves as a protection for the eggs until they are hatched. Cochineal is now furnished not only by Mexico and Peru, but also by Algiers and southern Spain. It is collected thrice in the seven months of the season. The insects are carefully brushed from the branches of the cactus into bags and are then killed by immersion in hot water, or by exposure to the sun, steam or the heat of an oven—much of the variety of appearance in the commercial article being caused by the mode of treatment.

The dried insect has the form of irregular, fluted and concave grains, of which about 70,000 go to a pound. The best crop is the first of the season, which consists of the unimpregnated females; the later crops include an admixture of young insects and skins, which contain proportionally little colouring matter.

Cochineal owes its tinctorial power to the presence of a substance termed cochinealin or carminic acid, $C_{22}H_{20}O_{13}$ (the formula shown by Dimeoth in 1920), which may be prepared from the aqueous decoction of cochineal. Cochineal also contains a fat and wax; cochineal wax or coccerin, $C_{30}H_{60}(C_{31}H_{61}O_2)_2$, may be extracted by using benzene; the fat is a glyceryl myristate $C_3H_5(C_{14}H_{27}O_2)_3$.

COCHLÄUS (DOBNECK), **JOHANN** (1479–1552), German humanist and controversialist, was born at Wendelstein (near Nuremberg), whence the punning surname Cochläus (spiral). In 1507 he graduated at Cologne and published under the name of Wendelstein his first piece, *In musicam exhortatorium*. He then became a schoolmaster at Nuremberg. In 1515 he was at Bologna, hearing (with disgust) Eck's famous disputation against usury, and associating with Ulrich von Hutten and the humanists. He took his doctor's degree at Ferrara (1517), and spent some time in Rome, where he was ordained priest. In 1520 he became dean of the Liebfrauenkirche at Frankfurt, where he first entered the lists as a controversialist against the party of Martin Luther, developing that bitter hatred of the Reformation which animated his forceful but shallow ascription to the movement of the meanest motives, due to a quarrel between the Dominicans and Augustinians. Luther would not meet him in discussion at Mainz in 1521. He was present at the diets of Worms, Regensburg, Speyer and Augsburg.

The peasants' war drove him from Frankfurt; he obtained (1526) a canonry at Mainz; in 1529 he became secretary to Duke George of Saxony, at Dresden and Meissen. The death of his patron (1539) compelled him to take flight. He became canon (Sept. 1539) at Breslau, where he died on Jan. 10, 1552.

His best known work is *Commentaria de Actis et scriptis Lutheris* (1549; German ed. 1580 and 1582). His *Kleine Schriften* were edited by J. Schweizer (1920).

See M. Spahn, *Johannes Cochläus* (1898).

COCK, EDWARD (1805–1892), British surgeon, born in 1805, was a nephew of the surgeon Sir Astley Cooper (*q.v.*) and through him became at an early age a member of the staff of the Borough hospital in London. Cock worked in the dissecting room there for 13 years.

He became in 1838 assistant surgeon at Guy's hospital, where from 1849 to 1871 he was surgeon and from 1871 consulting surgeon. He rose to be president of the College of Surgeons in 1869. He was an excellent anatomist, a bold operator and has been called a clear and incisive writer. Although he was afflicted with a stutter, he frequently utilized it in lecturing with humorous effect and for emphasis.

From 1843 to 1849 he was editor of *Guy's Hospital Reports*, which contain many of his papers, particularly on stricture of the urethra, puncture of the bladder, injuries to the head and hernia. He has been credited with being the first English surgeon to perform pharyngotomy with success and also as one of the first to succeed in trephining for middle meningeal haemorrhage. The operation of opening the urethra through the perinaeum became known by his name.

He died at Kingston, in 1892.

COCKADE, a knot of ribbons or a rosette worn as a badge, particularly in modern usage as part of the livery of servants. The cockade was at first the button and loop or clasp which "cocked" up the side of an ordinary slouch hat. The word first appears in this sense in Rabelais in the phrase *"bonnet à la coquarde,"* explained by Cotgrave (1611) as a "Spanish cap or fashion of bonnet used by substantial men of yore . . . worne proudly or peartly on th' one side." The bunch of ribbons as a party badge developed from this button and loop. The Stuarts' badge was a white rose, and the resulting white cockade figured in Jacobite songs. William III's cockade was of yellow, and the house of Hanover introduced theirs of black, which in its spiked or circular form of leather came to be worn by the royal coachmen and grooms and the servants of all officials or members of the services.

At the outbreak of the French Revolution of 1789, cockades of green ribbon were adopted. These afterward gave place to the tricolour cockade, which is said to have been a mixture of the traditional colours of Paris (red and blue) with the white of the Bourbons, the early revolutionists being still royalists. The French army wore the tricolour cockade until the Restoration. Each nation had its cockade. Thus the Austrian was black and yellow, Bavarian light blue and white, Belgian black, yellow and red, French the tricolour, Prussian black and white, Russian green and white, and so on, following usually the national colours. Originally the wearing of a cockade as a badge was restricted to soldiers. There is still a trace of the cockade as a badge in certain military headgears in England and elsewhere. Otherwise it became entirely the mark of domestic service.

See *Genealogical Magasine*, vol. i–iii (1897–99); Racinet, *La Costume historique* (1888).

COCKAIGNE (COCKAYNE), **LAND OF,** an imaginary country, a mediaeval Utopia where life was a continual round of luxurious idleness. The origin of the Italian word *cocagna* has been much disputed. It seems safest to connect it, as do Grimm and Littré, ultimately with Lat. *coquere*, through a word meaning "cake," the literal sense thus being "The Land of Cakes." In Cockaigne the rivers were of wine, the houses were built of cake and barley sugar, the streets were paved with pastry and the shops supplied goods for nothing. Roast geese and fowls wandered about inviting folks to eat them, and buttered larks fell from the skies like manna.

There is a 13th-century French *fabliau, Cocaigne*, which was possibly intended to ridicule the fable of the mythical Avalon, "the Island of the Blest." The 13th-century English poem *The Land of Cockaygne* is a satire on monastic life. The term has been humorously applied to London, and by the poet Boileau to the Paris of the rich. The word has been frequently confused with Cockney (*q.v.*).

COCKATOO (KAKATOEINAE), a group of parrots confined to the Australian region and characterized by a crest of feathers on the head; this can be raised at will. They live in flocks in woods, feeding on fruit, seeds and insects. The note is harsh and their powers of vocal imitation limited.

The well-known sulphur-crested cockatoo (*Kakatoe galerita*) inhabits Australia, where it does much damage to the newly sown grain. The white eggs, two in number, are deposited in hollow trees or fissures in rocks. It also ranges northeast to Aru, New Guinea and New Ireland. Leadbeater's cockatoo (*K. leadbeateri*) inhabits South Australia, and its white plumage is tinged with rose, deepening to salmon-pink under the wings; the crest is scarlet. It is a very shy bird.

The dark-plumaged funereal cockatoo or wyla (*Calyptorhynchus funereus*) is another Australian species. The smallest of the family is the cockateel (*Nymphicus hollandicus*), which has a long pointed tail. There are 5 genera and 17 species of cockatoos, some with a number of subspecies recognized.

COCKATRICE, a fabulous monster, the existence of which was firmly believed throughout ancient and mediaeval times. Descriptions and figures of it appeared in the natural history works of such writers as Pliny and Aldrovandus, those of the latter being published as late as the beginning of the 17th century.

Produced from a cock's egg hatched by a serpent, it was believed to possess the most deadly powers, plants withering at its touch and men and animals dying, poisoned, by its look.

The monster stood in awe, however, of the cock, the sound of whose crowing killed it. Consequently travellers were wont to take this bird with them in regions supposed to abound in cockatrices.

The weasel alone among mammals was unaffected by the glance of its evil eye, and attacked it at all times successfully; when wounded by the monster's teeth, it found a ready remedy in rue—the only plant which the cockatrice could not wither.

The term "cockatrice" is employed on four occasions in the English translation of the Bible, in all of which it denotes nothing more than an exceedingly venomous reptile; it seems also to be synonymous with "basilisk," the mythical king of serpents.

COCKBURN, SIR ALEXANDER JAMES EDMUND, 10TH BART. (1802–1880), lord chief justice of England, born Dec. 24, 1802, of ancient Scottish stock, the son of Alexander, fourth son of Sir James Cockburn, 6th baronet. His father was British envoy extraordinary and minister plenipotentiary to the state of Colombia, and married Yolande, daughter of the vicomte de Vignier. He was educated at Trinity Hall, Cambridge, of which he was elected a fellow and afterward an honorary fellow. He entered at the Middle Temple in 1825 and was called to the

bar in 1829. He joined the western circuit, and for some time such practice as he was able to obtain lay at the Devon sessions. In 1832, however, the petitions following the first general election after the Reform bill gave him an opening. The decisions of the committees had not been reported since 1821, and with M. C. Rowe, another member of the western circuit, Cockburn undertook a new series of reports. In 1833 he had his first parliamentary brief.

In 1847 he decided to stand for parliament and was elected, without a contest, Liberal M.P. for Southampton. His speech in the house of commons on behalf of the government in the Don Pacifico dispute with Greece commended him to Lord John Russell, who appointed him solicitor general in 1850 and attorney general in 1851, a post which he held till the resignation of the ministry in Feb. 1852. During the short administration of Lord Derby, which followed, Sir Frederic Thesiger was attorney general and Cockburn was engaged against him in the case of *R. v. Newman*, on the prosecution of Achilli, a criminal information for libel against Cardinal Newman. The jury which tried the case under Lord Campbell found the defense of justification not proved except in one particular. The verdict was set aside and a new trial ordered, but none ever took place. In Dec. 1852, under Lord Aberdeen's ministry, Cockburn became again attorney general, and so remained until 1856, taking part in many celebrated trials, notably leading for the crown in the trial of William Palmer, of Rugeley in Staffordshire, for poisoning. In 1854 Cockburn was made recorder of Bristol. In 1856 he became chief justice of the common pleas. He inherited the baronetcy in 1858.

In 1859 Lord Campbell became chancellor, and Cockburn became chief justice of the queen's bench, continuing as a judge for 24 years and dying in harness. On Saturday, Nov. 20, 1880, he presided over a court for the consideration of crown cases reserved; he walked home, and on that night he died of angina pectoris at his house in Hertford street.

Sir Alexander Cockburn earned and deserved a high reputation as a judge. He was a man of brilliant cleverness and rapid intuition. He had been a great advocate at the bar, fluent and persuasive rather than learned; before he died he was considered a good lawyer, some assigning unquestioned improvement in this respect to his frequent association on the bench with Blackburn. He had notoriously little sympathy with the Judicature acts. Many were of the opinion that he was inclined to make up his mind prematurely on the cases before him. But he was beyond doubt always in intention, and generally in fact, scrupulously fair. It was thought that he went out of his way to arrange to try *causes célèbres* himself. His successor, Lord Coleridge, writing in 1881 to Lord Bramwell to make the offer that he should try the murderer Lefroy as a last judicial act before retiring, added, "Poor dear Cockburn would hardly have given you such a chance." But Cockburn tried all cases which came before him, whether great or small, with the same thoroughness, courtesy and dignity, while he certainly gave great attention to the elaboration of his judgments and charges to juries. His summing up at the Tichborne trial at bar lasted 18 days.

The greatest public occasion on which Sir Alexander Cockburn acted, outside his usual judicial functions, was that of the "Alabama" arbitration, held at Geneva, Switz., in 1872, in which he represented the British government and dissented from the view taken by the majority of the arbitrators, without being able to convince them.

He prepared, with C. F. Adams, the representative of the United States, the English translation of the award of the arbitrators and published his reasons for dissenting in a vigorously worded document which did not meet with universal commendation. He admitted in substance the liability of England for the acts of the "Alabama," but not on the grounds on which the decision of the majority was based, and he held England not liable in respect of the "Florida" and the "Shenandoah."

In personal appearance Sir Alexander Cockburn was of small stature, but great dignity of deportment. He was fond of yachting and sport, and at the time of his death was engaged in writing a series of articles on the "History of the Chase in the 19th Century."

He had a high sense of the duties of his profession, and his utterance upon the limitations of advocacy, in his speech at the banquet given in the Middle Temple hall for Berryer, the celebrated French advocate, may be called the classical authority on the subject. Lord Brougham had spoken of "the first great duty of an advocate to reckon everything subordinate to the interests of his client." But the lord chief justice, replying to the toast of "the judges of England," said amid loud cheers from a distinguished assembly of lawyers, "The arms which an advocate wields he ought to use as a warrior, not as an assassin. He ought to uphold the interests of his clients *per fas*, not *per nefas*. He ought to know how to reconcile the interests of his clients with the eternal interests of truth and justice" (the *Times*, Nov. 9, 1864).

Sir Alexander Cockburn was never married, and the baronetcy became extinct at his death.

COCKBURN, ALICIA or ALISON (1713–1794), Scottish poet, author of one of the most exquisite of Scottish ballads, the "Flowers of the Forest," was the daughter of Robert Rutherfurd of Fairnalee, Selkirkshire, and was born on Oct. 8, 1713, and died on Nov. 22, 1794. There are two versions of this song—the one by Mrs. Cockburn, the other by Jean Elliot (1727–1805) of Minto. Both were founded on the remains of an ancient Border ballad. Mrs. Cockburn's—that beginning "I've seen the smiling of Fortune beguiling"—is said to have been written before her marriage to Patrick Cockburn of Ormiston in 1731, though not published till 1765.

It was composed many years before Jean Elliot's sister verses, written in 1756, beginning, "I've heard them liltin' at our ewe-milkin'." Robert Chambers stated that the ballad was written on the occasion of a great commercial disaster which ruined the fortunes of some Selkirkshire lairds. Later biographers, however, held it probable that it was written on the departure to London of a certain John Aikman, between whom and Alison there appears to have been an early attachment.

In 1731 she was married to Patrick Cockburn of Ormiston. After her marriage Mrs. Cockburn came to know the intellectual and aristocratic celebrities of the times. In 1745 she vented her Whiggism in a squib upon Prince Charlie and narrowly escaped being taken by the Highland guard as she was driving through Edinburgh in the family coach of the Keiths of Ravelston with the parody in her pocket.

Mrs. Cockburn was an indefatigable letter writer and a composer of parodies, squibs, toasts and so-called character sketches—then a favourite form of composition—like the other wits of the day. The "Flowers of the Forest," however, was the only thing she wrote that came to be considered of great literary merit.

At her house on Castle hill, and afterward in Crichton street, Mrs. Cockburn received Mackenzie, Robertson, Hume, Home, Monboddo, the Keiths of Ravelston, the Balcarres family, Lady Anne Barnard, the author of "Auld Robin Gray," and others. As a Rutherfurd she was a connection of Sir Walter Scott's mother, and was her intimate friend. Scott, at six years old, is said to have given as a reason for his liking for Mrs. Cockburn that she was a "virtuoso like himself."

See her *Letters and Memorials . . .*, with notes by T. Craig Brown (Edinburgh, 1900).

COCKBURN, SIR GEORGE, BART. (1772–1853), British admiral, second son of Sir James Cockburn, Bart., and uncle of Lord Chief Justice Cockburn, entered the navy at the age of nine, though he did not go to sea until 1786. After serving on the home station and in the East Indies and the Mediterranean, he

assisted, as captain of the "Minerve," at the blockade of Leghorn in 1796, and fought a gallant action with the Spanish frigate "Sabina," which he took. He was present at the battle of Cape St. Vincent. In 1809, in command of the naval force on shore, he contributed greatly to the reduction of Martinique, and signed the capitulation by which that island was handed over to Great Britain.

After service in the Scheldt and at the defense of Cadiz he was sent in 1811 on an unsuccessful mission for the reconciliation of Spain and its American colonies. In 1813–14, as second in command to Sir J. B. Warren, he took part in the War of 1812, especially in the capture of Washington. In the autumn of 1815 he carried out, in the "Northumberland," the sentence of deportation to St. Helena which has been passed upon Bonaparte. He was promoted admiral in 1837; he became senior naval lord in 1841, and held office in that capacity till 1846. In 1851 he was made admiral of the fleet.

Cockburn died on Aug. 19, 1853.

COCKBURN, HENRY THOMAS (1779–1854), Scottish judge, with the style of Lord Cockburn, was born in Edinburgh on Oct. 26, 1779. His father was a baron of the Scottish court of exchequer.

He was educated at the high school and the University of Edinburgh, and he was a member of the Speculative society, to which Sir Walter Scott, Brougham and Jeffrey belonged. He entered the faculty of advocates in 1800 and attached himself, though his connections were Tory, to the Whig or Liberal party, which then offered few prospects to ambitious men. On the accession of Earl Grey's ministry in 1830 he became solicitor general for Scotland. In 1834 he was raised to the bench, and on taking his seat as a judge in the court of session he adopted the title of Lord Cockburn.

Cockburn's forensic style was remarkable for its clearness, pathos and simplicity, and his conversational powers were unrivalled among his contemporaries. In 1852 he published his biography of Lord Jeffrey, and the *Memorials of His Time* appeared posthumously in 1856 (new ed., with introduction by his grandson, H. A. Cockburn, 1909).

Cockburn died on April 26, 1854, at his mansion of Bonaly, near Edinburgh.

COCKCHAFER (*Melolontha melolontha*), a common European beetle whose larva is destructive to the roots of crops. The white grub spends several years in the soil before emerging as a large beetle which feeds on the leaves of trees and may often be seen flying in large numbers at dusk.

(*See* CHAFER; COLEOPTERA.)

COCKCROFT, SIR JOHN DOUGLAS (1897–), British physicist and co-winner of the Nobel prize, was born at Todmorden, Yorkshire, Eng., on May 27, 1897. He was educated at Todmorden Secondary school, at Manchester university and at St. John's college, Cambridge, of which he was a fellow from 1928 to 1946 and an honorary fellow from 1947.

At a meeting of the Royal society on April 28, 1932, Lord Rutherford announced that two of his workers at the Cavendish laboratory, Cambridge—Cockcroft and E. T. S. Walton—"had successfully disintegrated the nuclei of lithium and other light elements by protons entirely artificially generated by high energy potentials." On Nov. 15, 1951, the Royal Swedish Academy of Sciences announced the award of the Nobel prize for physics jointly to Cockcroft and Walton for "their pioneer work on the transmutation of atomic nuclei by artificially accelerated atomic particles."

Cockcroft was Jacksonian professor of natural philosophy in Cambridge university, 1939–46; from 1941 to 1944, however, he served as chief superintendent, air defense research and development establishment, ministry of supply, and from 1944 to 1946 he was director of the atomic energy division, National Research council of Canada. In 1946 he became director of the atomic energy research establishment, ministry of supply, at Harwell, Eng. He was also chairman of the defense research policy committee and scientific adviser, ministry of defense, from 1952 to 1954, and served as a member of the British Broadcasting corporation's Scientific Advisory committee, 1948–52.

Cockcroft was elected a fellow of the Royal society in 1936, was knighted in 1948 and created knight commander of the Bath in 1953.

COCKER, EDWARD (1631–1675), reputed author of the famous *Arithmetick*, the popularity of which added a phrase ("according to Cocker") to the list of English proverbialisms, was an English engraver who also taught writing and arithmetic.

Samuel Pepys, in his *Diary*, makes very favourable mention of Cocker, who appears to have displayed great skill in his art.

Cocker's *Arithmetick*, the 52nd edition of which appeared in 1748 and which passed through about 112 editions in all, was not published during the lifetime of the reputed author, the first impression bearing the date of 1678.

Augustus de Morgan in his *Arithmetical Books* (1847) adduced proofs that the work was a forgery of the editor and publisher John Hawkins. De Morgan condemns the *Arithmetick* as a diffuse compilation from older and better works and dates "a very great deterioration in elementary works on arithmetic" from the appearance of the book, which owed its celebrity far more to persistent puffing than to its merits.

De Morgan added that "This same Edward Cocker must have had great reputation, since a bad book under his name pushed out the good ones."

Cocker's writing manuals include *Art's Glory, or the Penman's Treasure* (1657); *The Pen's Transcendencie or Faire Writing's Labyrinth* (1657); and *Pen's Triumph* (1658).

Other works are *Cocker's Morals or the Muses spring-garden, sententious disticks and poems fitted for all publick and private grammar and writing-schools, for the scholars of the first to turn into Latin, and for those of the other to transcribe into all their various and curious hands* (1685) and *Cocker's English Dictionary; interpreting the most refined and difficult Words in Divinity, Philosophy, Law, Physick, Mathematics, Husbandry, Mechanicks, &c.* (1704).

COCKERELL, CHARLES ROBERT (1788–1863), British architect, was born in London on April 28, 1788. After studying under his father, Samuel Pepys Cockerell (1754–1827), he went abroad in 1810 and studied the great architectural remains of Greece, Italy and Asia Minor. At Aegina, Phigaleia and other places of interest, he conducted excavations on a large scale, enriching the British museum with many fine fragments. He became R.A. in 1829, and from 1840 to 1857 was professor of architecture at the academy. In 1837 he was appointed architect to the Bank of England. Among his principal works are the Taylorian building, Oxford (1842), and the completion of St. George's hall, Liverpool, and of the Fitzwilliam museum, Cambridge, with some important bank buildings. Cockerell's best conceptions were inspired by classic models; examples of his Gothic style are the college at Lampeter and the chapel at Harrow. His son, FREDERICK PEPYS COCKERELL (1833–78), was also a distinguished architect.

COCKERILL, WILLIAM (1759–1832), English inventor and machinist, was born in England in 1759. He went to Belgium as a simple mechanic, and in 1799 constructed at Verviers the first wool-carding and wool-spinning machines on the continent. In 1807 he established a large machine workshop at Liège. Orders soon poured in on him from all over Europe, and he amassed a large fortune. In 1810 he was granted the rights of naturalization by Napoleon I, and in 1812 handed over the management of his business to his youngest son, John Cockerill (1790–1840), who largely extended his father's business. King William I of the Netherlands secured him a site at Seraing, where he built large works, including an iron foundry and blast furnace. The construction of the Belgian railways in 1834 gave a great impetus to these works, branches of which had already been opened in France, Germany and Poland. John Cockerill had practically concluded negotiations to construct the Russian government railways when his constitution, undermined by overwork, broke down. He died at Warsaw on June 19, 1840. The iron works, among the largest in Europe, were carried on under the name of La Société Cockerill at Seraing.

COCKERMOUTH, a small town and urban district of Cumberland, Eng., 32 mi. S.W. of Carlisle, by the London Midland Region railway. Pop. (1951) 5,234. Area 3.2 sq.mi. It is situated at the confluence of the Derwent and Cocker at a focus of ways among the lower western hills of the Lake district. Settlement in the neighbourhood goes back at least to Roman times, there being a small fort 1 mi. W. of the town at Papcastle.

Cockermouth (*Cokermuth, Cokermue*) was the head of the barony of Allerdale, created and granted to Waltheof in the 12th century. Waltheof probably built the castle, under the shelter of which the town grew up. There are remains of Norman work in the keep, but the castle is in part modernized as a residence. The town received no royal charter, but the earliest records mention it as a borough. In 1295 it returned two members to parliament and then not again until 1640. In 1867 it had one member, and in 1885 it was disfranchised. In 1221 William de Fortibus, earl of Albemarle, was granted a market. The Michaelmas fair existed in 1343, and in 1374 there were two horse fairs, on Whit Monday and at Michaelmas. In 1638 a fair every Wednesday from the first week in May till Michaelmas was granted. The grammar school was founded in 1676. The county industrial school was established in the town and engineering and agricultural machine works, a brewery and a malt house were also established there. The town suffered severe depression in the 1930s, unemployment among men being 45.3% in April 1934. The poet Wordsworth was born there.

COCKFIGHTING or COCKING, the sport of pitting gamecocks to fight, and breeding and training them for the purpose. The game fowl is now probably the nearest to the Indian red jungle fowl (*Gallus gallus*), from which all domestic fowls are believed to be descended. The sport was popular in ancient times in India, China, Persia and other eastern countries, and was introduced into Greece in the time of Themistocles. The latter, while moving with his army against the Persians, observed two cocks fighting desperately and, stopping his troops, inspired them by calling their attention to the valour and obstinacy of the feathered warriors. In honour of the ensuing victory of the Greeks cockfights were thenceforth held annually at Athens, at first in a patriotic and religious spirit, but afterward purely for the love of the sport. On the chair of the high priest of Dionysus, in the Theatre at Athens, there is carved a beautiful figure of a winged Eros holding a gamecock just about to fight. Lucian makes Solon speak of quail fighting and cocking, and evidently is referring to an era in Asia, about 3,000 years ago, when cocking enthusiasts, lacking the cocks, set quail to fighting quail, and partridges to fighting partridges, since both are natural fighters. From Athens the sport spread throughout Greece, Asia Minor and Sicily, the best cocks being bred in Alexandria, Delos, Rhodes and Tanagra. For a long time the Romans affected to despise this "Greek diversion," but ended by adopting it so enthusiastically that Columella (1st century A.D.) complained that its devotees often spent their whole patrimony in betting at the pitside.

It is not definitely established when metal spurs first were slipped over the natural spurs of the gamecocks. The first used were silver spurs; later, iron spurs, then steel spurs. The metal spur has been known for hundreds of years. The modern short metal spur is 1½ in. or less in length; the long spur scales from 2 to about 2½ in.

From Rome cocking spread northward and, although opposed by the Christian church, nevertheless became popular in Great Britain, the Low Countries, Italy, Germany, Spain and its colonies. It was probably introduced into England by the Romans before Caesar's time. William Fitzstephen first speaks of it in the time of Henry II as sport for schoolboys on holidays, and particularly on Shrove Tuesday, the masters themselves directing the fights, or mains, from which they derived a material advantage, as the dead birds fell to them.

Cockfighting became very popular throughout England and Wales, as well as in Scotland, where it was introduced in 1681. Occasionally the authorities tried to repress it, especially Cromwell, who put a stop to it for a brief period, but the Restoration re-established it among the national pastimes.

From the time of Henry VIII, who added the famous royal cockpit to his palace of Whitehall, cocking was called the "royal diversion," and the Stuarts, particularly James I and Charles II, were among its most enthusiastic devotees, their example being followed by the gentry down to the 19th century. The king's cockmaster presided over the pits at Whitehall. Gervase Markham, in his *Pleasures of Princes* (1614), wrote "Of the Choyce, Ordring, Breeding and Dyeting of the fighting Cocke for Battell," his quaint directions being of the most explicit nature.

Cocking mains usually consisted of fights between an agreed number of pairs of birds, the majority of victories deciding the main; but there were two other varieties that aroused the particular ire of moralists. These were the "battle royal" in which a number of birds were "set" (*i.e.*, placed in the pit at the same time) and allowed to remain until all but one, the victor, were killed or disabled; and the "Welsh main," in which eight pairs were matched, the eight victors being again paired, then four, and finally the last surviving pair.

Among famous London cockpits were those at Westminster, in Drury lane, Jewin street and Birdcage walk (depicted by Hogarth). The pits were circular in shape with a matted stage about 20 ft. in diameter and surrounded by a barrier to keep the birds from falling off. Upon this barrier the first row of the audience leaned. Hardly a town in the kingdom was without its cockpit, which offered the sporting classes opportunities for betting.

Perhaps the most famous main in England took place at Lincoln in 1830 between the birds of Joseph Gilliver, the most celebrated breeder, or "feeder," of his day, and those of the earl of Derby. The conditions called for seven birds a side, and the stakes were 5,000 guineas the main and 1,000 guineas each match. The main was won by Gilliver by five matches to two. His grandson was also a breeder, and the blood of his cocks still runs in the best breeds of Great Britain and America. Another famous breeder was Bellyse of Audlem, the principal figure in the great mains fought at Chester during race week at the beginning of the 19th century. His favourite breed was the white pile, and Cheshire Piles are still much-fancied birds. Others were Irish Brown-Reds, Lancashire Black-Reds and Staffordshire Duns.

In Wales, as well as some parts of England, cocking mains took place regularly in churchyards, and in many instances even inside the churches themselves. Sundays, wakes and church festivals were favorite occasions for them. The habit of holding mains in schools was common from the 12th to about the middle of the 19th century. When cocking was at its height, the pupils of many schools were made a special allowance for purchasing fighting cocks, and parents were expected to contribute to the expenses of the annual main on Shrove Tuesday, this money being called "cockpence." Cockfighting was prohibited by law in Great Britain in 1849.

Cocking was early introduced into America though it was always frowned upon in New England. Some of the older states, as Massachusetts, forbade it by passing laws against cruelty as early as 1836, and it is expressly prohibited in Canada and in most states of the U.S. or is repressed by general laws for the prevention of cruelty to animals. Although cockfighting has ceased as a public sport in the United States, Canada and the British Isles, it continues to exist in private in those countries. Portable mains are moved from place to place, to avoid police raids, and Sunday morning usually is "fight time." In the United States the sport is extremely popular along the Atlantic seaboard and in the south.

Cockfighting is not recognized as a form of sport by the Latin-American countries in general. In Argentina cockfighting was once one of the most popular amusements; but it was suppressed by police measures, although it persisted in several provinces. Paraguay prohibited it by law. But in Cuba cockfighting continued to be a patronized sport regulated by the government. Cubans always supported it; and, although it was prohibited for a time, it was reinstated during the Gómez administration and was later regulated by municipal decrees. Puerto Rico became an important cockfighting centre. Breeders of gamecocks stress pedigree. They regard as fit for championship honours only those birds which have been produced by the blending of strains of the

world's most courageous cocks, through hundreds of years. Famous among the strains of the 20th century are the Shawlnecks, Irish Gilders, Eslin Red-Quills, Dominiques, Claibornes, Baltimore Topknots, War-Horses, Irish Grays and Hammond-Gordons. Gamecocks usually are put to the main when between one and two years of age. But, preceding their entrance into the fighting pit, they are given intensive training. They do not need to be encouraged to fight. That is their heritage. But great preparations are made to perfect their physical condition and to teach them the art of fighting.

As youngsters, they are permitted a great deal of exercise. This is to develop muscles. When they are deemed old enough to be readied for battle, they are trained for a number of days. Chief features of their special diet are cooked corn meal, chopped hard-boiled eggs and occasional helpings of raw beef. This is augmented by regular fowl feed. The birds are massaged with a mixture of alcohol and ammonia, which toughens their skin. Their wings are trimmed at the slope; the hackle and the rump feathers are shortened; the comb is cut as close as possible, so as to reduce it as a target for an enemy bird. In time, the cock is taken to a main, held by a trainer, and brought within a foot, or two, of another trainee, similarly held. The frenzied efforts of the cocks to get at each other adds strength to their muscles. Later the birds get actual fight training by being pitted against each other, with heavily padded leather over their spurs.

In ancient times cocks were permitted to fight until one or the other was killed. In the more modern era, the rules were amended somewhat. Although some fights still are to an absolute finish, others permit the withdrawal at any time of a badly damaged cock. Other rules fix a time limit for each fight. The average cockpit is 18 ft. in diameter, with sidewalls about 16 in. high.

Those who enjoy cockfights insist that the zest in the sport is provided by the many chances to gamble before a fight begins and all during its progress. Odds against one bird or the other are constantly changed as the tide of battle shifts, and in some prolonged fights a score or more of wages are made on the outcome.

On those rare occasions when a gamecock, taking the worst of it, decides he does not wish to continue battle, he makes his intent known by lifting his hackle. The under part of the hackle is edged with white feathers, and from this act is derived the expression "showing the white feather," which means cowardice. When a cock refuses to fight longer, his handler puts him breast-to-breast with the other bird. If he still refuses, then it is ruled that he has quit, and the fight ends.

At all mains, the judge is in supreme control. His word is absolute law, even as to the gambling, and it is binding on all those identified, either officially, or unofficially, with a cockfight. There is no appeal from his decisions in anything relating to the main. Because of this, only the highest type of citizen in a cockfighting community is regarded as eligible to serve as judge.

BIBLIOGRAPHY.—Cockfighting possesses an extensive literature of its own. *See* Gervase Markham, *Pleasures of Princes* (1614); Blain, *Rural Sports* (1853); "Game Cocks and Cock-Fighting," *Outing*, vol. xxxix; "A Modest Commendation of Cock-Fighting," *Blackwood's Magazine*, vol. xxii; "Cock-Fighting in Schools," *Chambers' Magazine*, vol. lxv. (F. G. M.)

COCK LANE GHOST, a supposed apparition, the vagaries of which attracted extraordinary public attention in London during 1762. At a house in Cock lane, Smithfield, tenanted by one Parsons, knockings and other noises were said to occur at night varied by the appearance of a luminous figure, alleged to be the ghost of a Mrs. Kent who had died in the house about two years before. A thorough investigation revealed that Parsons' daughter, a child of 11, was the source of the disturbance. The object of the Parsons family seems to have been to accuse the husband of the deceased woman of murdering her, with a view of blackmail. Parsons was prosecuted and condemned to the pillory.

See A. Lang, *Cock Lane and Common Sense* (1894).

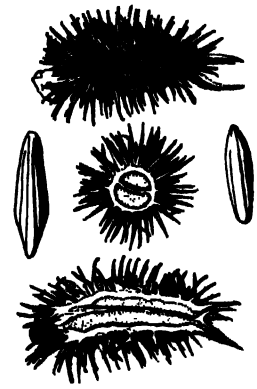
COCKLE, SIR JAMES (1819–1895), English lawyer and mathematician, was born on Jan. 14, 1819. He was the second son of James Cockle, a surgeon, of Great Oakley, Essex. Educated at Charterhouse and Trinity college, Cambridge, he entered the Middle Temple in 1838, practising as a special pleader in 1845 and being called in 1846. He joined the western circuit and was appointed chief justice of Queensland in 1863. He was knighted in 1869, retired from the bench and returned to England in 1879.

Cockle is more remembered for his mathematical and scientific investigations than as a lawyer. He attacked the problem of resolving the higher algebraic equations, notwithstanding Abel's proof that a solution by radicals was impossible. In this field Cockle achieved some notable results, among which is his reproduction of Sir William Hamilton's modification of Abel's theorem. Algebraic forms were a favourite object of his studies, and he discovered and developed the theory of criticoids, or differential invariants; he also made contributions to the theory of differential equations. He was a member of many scientific societies in Queensland and England. He died in London on Jan. 27, 1895.

A volume containing his scientific and mathematical researches made during the years 1864–77 was presented to the British museum in 1897 by his widow.

See the obituary notice by the Rev. R. Harley in *Proc. Roy. Soc.*, vol. 59.

COCKLE, a bivalved marine mollusc of the genus *Cardium*, allied to the oyster and placed in the class Lamellibranchia. About 200 living species of cockles are known and more than 330 fossil forms have been described. The common or edible cockle (*Cardium edule*) is the best-known example and is of some economic importance.



The two valves of the shell of the cockle are similar and are characterized by a prominent umbo (*see* LAMELLIBRANCHIA) from which a number of prominent ribs radiate over the surface of the shell. The animal has a long and pointed foot with a kneelike bend in it. The mantle is produced into two short "siphons" which bear numerous fingerlike processes. In certain species these processes carry eyes at their tips. The cockle is placed in the order Eulamellibranchiata.

The cockles live on the sea bottom and are usually found buried below the surface. The common cockle, and probably most of the other species, rarely penetrates below one inch from the surface. The muscular, pointed foot enables it to dig into and plough its way through sand and mud. It has a moderately wide range of habitat but is rarely found on any soil other than sand and mud. Wright states that *Cardium edule* thrives best in estuarine waters, where the salinity is a little less than that of normal sea water. Cockle beds formed on the open coast are rarely permanent. In water of high or very low salinity the shell is subject to certain modifications of shape and weight. The cockle, like the rest of the Lamellibranchia, has no organs of mastication. It feeds on minute animals and plants and on the organic particles found in sea water. The spores of algae, foraminifera, diatoms, etc., usually constitute its diet. The animal is a "current feeder," the food being drawn into the branchial chamber in the water currents produced by the lower siphon. In England and Wales the most important cockle fisheries are in the Thames estuary, the Wash, Carmarthen and Morecambe bays. The animals are gathered by hand or by various kinds of rakes and scrapers and are boiled (in certain places by special methods to ensure the destruction of typhoid bacilli) before being dispatched to market. The nutritional value of the common cockle is fairly high, though its tissues contain less protein and fat than those of the oyster and mussel.

COCKLEBUR, the name given in the U.S. to species of *Xanthium*, of the family Compositae, called also clotbur and burweed, which in agricultural districts are pernicious weeds. They are coarse, rough and sometimes spiny annual herbs with much-branched stems, 1 ft. to 6 ft. high, and mostly long-stalked, variously lobed leaves. The staminate (male) and pistillate (female) flowers, both small and inconspicuous, are borne on the same plant, the staminate clustered at the ends of branches and

the pistillate in the axils of the leaves. The fruit (achene) is enclosed in pairs in an oblong bur, about an inch in length, covered with hooked spines and ending in a one- or two-toothed beak. The ripe burs adhere to the hair of farm animals, which widely disseminate the plant. When abundant, mostly on alluvial soils, cockleburs are injurious to crops, but they may be controlled by intensive cultivation or mowing. The germinating seeds and young plants, while in the seed leaf stage, contain a toxic glucoside and cause fatal poisoning when eaten by livestock.

COCKNEY, a colloquial name applied to Londoners generally but more properly confined to those born within the sound of the bells of St. Mary-le-Bow church. The origin of the word has been the subject of many guesses, but the historical examination of the various uses of "cockney," by Sir James Murray (see *Academy,* May 10, 1890, and the *New English Dictionary,* s.v.), shows that the earliest form of the word is *cokenay* or *cokeney; i.e.,* the *ey* or egg, and *coken,* genitive plural of "cock," "cocks' eggs" being the name given to the small and malformed eggs sometimes laid by young hens (*cf.* Langland, *Piers Plowman,* A, vii, 272). The word then applied to a child overlong nursed by its mother, hence to a simpleton, and Chaucer, *Reeve's Tale,* used it with *daf; i.e.,* a fool. The application of the term by country folk to town-bred people, with their ignorance of country ways, is easy. Thus Robert Whittington or Whitinton (*fl.* 1520) speaks of the "cokneys" in such "great cytees as London, York, Perusy" (Perugia). It was not till the beginning of the 17th century that "cockney" appears to have been confined to the inhabitants of London.

The so-called cockney accent was chiefly characterized in the first part of the 19th century by the substitution of a *v* for a *w,* or vice versa. The chief consonantal variation which now exists is perhaps the change of *th* to *f* or *v,* as in "fing" for thing, or "farver" for farther. This and the vowel sound change from *ou* to *ah,* as in "abaht" for "about," were illustrated in the "coster" songs of Albert Chevalier. The most marked change of vowel sound is that of *ei* for *ai,* so that "daily" becomes "dyly." The omission of *h* is not peculiar to cockney.

COCK OF THE ROCK, birds of the genus *Rupicola* (subfamily Rupicolinae) of the cotingas (allied to the manakins; *q.v.*), found in the Amazon valley. They are about the size of a pigeon, with orange-coloured plumage, a pronounced crest and orange-red flesh; they build their nests on rock. The males hold elaborate "dancing parties." (*See* BELLBIRD; CHATTERER; UMBRELLA BIRD.)

COCKPIT, originally an enclosed place in which cockfighting (*q.v.*) was carried on. On the site of an old cockpit opposite Whitehall in London was a block of buildings, used from the 17th century as offices by the treasury and the privy council, for which the old name survived till the early 19th century. The name of a theatre in London, built early in the 17th century on the site of Drury Lane theatre. Applied formerly to a cabin on the lower deck of a man-of-war, where the wounded were tended.

COCKROACH [1], the name applied to members of the Blattidae, a family of orthopterous insects, with flattened bodies, long, threadlike antennae and shining leathery integument. They are eminently tropical, but certain species have become widely disseminated through commerce and are now cosmopolitan. Cockroaches are nocturnal in habit, hiding themselves during the day. The domestic species are omnivorous but are especially addicted to starchy or sweetened matter of various kinds; they also attack food, paper, clothing, books, shoes, bones, etc., and dead insects. As a rule they injure and soil far more than they consume, and most species emit a disagreeable odour.

The oriental cockroach (*Blatta orientalis*), a cosmopolitan household pest, is dark brown; males are short-winged, females subapterous (*see* ORTHOPTERA, fig. 1). The larger, fully winged American cockroach (*Periplaneta americana*) infests buildings throughout the tropics and warm-temperate zones. The German cockroach (*Blattella germanica*), small and pale with two dark lines on the pronotum, occurs with man from the tropics to high latitudes. Blattid eggs are laid in cases (oöthecae) which are carried protruding from the female's body until hidden in some crevice. Those of *P. americana* contain 10 to 16 eggs which hatch in 40–45 days; nymphal life is 11–14 months, adult life 3–12 months. *B. orientalis* lives about one year.

About 1,500 species of cockroaches are known, most of them tropical; only 53 species, many introduced, occur in North America, and Great Britain has only two native species. Although blattids are usually sombrely coloured, some tropical species are elegant in form and beautiful in coloration. The delicate green *Panchlorae* of the American tropics, sometimes introduced with bananas into Great Britain and the United States, are ovoviparous. Some *Blaberinae* are giants with a wingspread of more than 5 in. Insecticides used for cockroach control, most of which are poisonous to animals and man, include chlordane, one of the most effective, DDT, pyrethrum and sodium fluoride, which was used for many years. Although these insects are usually viewed with disgust, they are not devoid of interest. They are the most primitive of living winged insects, and are among the oldest fossil insects. Their generalized structure and large size make them convenient for study and dissection, and they are widely used as the most suitable type for commencing the scientific study of insects. *See* also ORTHOPTERA.

Lucas, *British Orthoptera* (1920); Morgan Hebard, *Blattidae of North America* (1917); Phil Rau, "Life History of the American Cockroach," *Entomological News,* vol. li (1940); E. A. Back, *Cockroach and Their Control,* U.S. Department of Agriculture leaflet 144 (1937). (T. H. HL.)

COCKSCOMB, cultivated forms of *Celosia argentea cristata* (family Amaranthaceae), in which the inflorescence is monstrous, forming a flat "fasciated" axis bearing numerous small flowers. The plant is a low-growing herbaceous annual, bearing a large, comblike, feathery, rolled or grotesque cluster of dark red, scarlet, purplish or yellow flowers.

Celosia floribunda, a related plant, is cultivated in California under the name cockscomb, but is shrubby.

COCKTON, HENRY (1807–1853), English humorous novelist, was born in London Dec. 7, 1807, and died at Bury St. Edmund's June 26, 1853. He is best known as the author of *Valentine Vox, the Ventriloquist* (1840) and *Sylvester Sound, the Somnambulist* (1844).

COCOA (CACAO). Cocoa and chocolate come from small trees of the family Sterculiaceae, generally *Theobroma cacao,* rarely *T. pentagona* or *T. spherocarpa;* not to be confused with the coconut palm (*Cocos nucifera*) or with the South American coca shrub (*Erythroxylon coca*), the leaves of which contain a stimulant, cocaine. The seeds or beans of *Theobroma* (Greek for "food for the gods") provide, on processing, materials useful as food and drink. This fact was well known to the pre-Columbian natives of its source area, tropical Middle America, particularly to the Mayas and Aztecs, who used the beans also as a medium of exchange. Some think Columbus took specimen cocoa beans to Europe; in any case, Spain early in the 16th century was made aware of this gift of the new world by letters from Hernan Cortes to the Spanish monarch Charles V. It was introduced into Spain in 1528, almost a century before tea and coffee. Its use spread very slowly to other parts of Europe and the world, there being little mention of it elsewhere until the early part of the 17th century. Fashionable chocolate houses eventually developed. As late as 1850 annual production was less than 20,000 tons; in 1900 it was less than 100,000 tons.

The Cocoa Farm.—Most of the world's cocoa production comes from the modest two to five acres of native small farmers. Probably not more than 10% of the African production of base-

[1] The word is a corruption of Sp. *cucaracha;* in the U.S. it is commonly abbreviated to "roach."

grade cocoa, but more of the American production of flavour grades, is from larger plantations under co-operative native groups or non-native management. Preparation of the area for planting consists mostly in slashing and burning existing vegetation, perhaps girdling tall trees and leaving others for shade. Planting, except under more advanced management, is by rather closely spaced seeding, sometimes later thinned to keep the stronger plants. In other cases, nursery-grown and selected seedlings are transplanted when about two feet high, with field spacing ten feet or more apart. There is some tendency to abandon the use of seedlings in favour of more certain vegetative propagation of superior strains by cuttings and bud grafting. Shade by food plants, especially bananas, is provided in most areas for the thinner plantings. The tree, which would grow eventually to 30 to 40 ft. in height, is generally pruned to 15 to 25 ft. to aid harvesting. There is little cultivation or fertilization, other than slashing undergrowth. The tree begins to bloom and fruit three or four years after planting and reaches full production about the eighth year. There is disagreement as to the length of fruiting life, but 30 to 40 years is common and nearly 100 years is reported. There is some evidence that from the standpoint of production and disease control it is desirable to replace trees after 15 to 30 years.

Several diseases attack the tree or the fruit. Virus diseases called "swollen shoot" constitute a major menace in West Africa especially, where as many as 15,000,000 trees are affected annually; the best remedy is to cut and burn the infected trees. A fungus disease, "witches'-broom," caused by *Marasmius perniciosus*, a parasite mushroom, has been very destructive in the West Indian area and in some parts of South America. *Phytophthora*, a fungus, does damage, as do capsid bugs (especially *Sahlbergella singularis*) and various rots of the fruit pods, including the fungus *Monilia*.

Harvesting and Treatment.—A full-grown tree produces annually approximately 6,000 small pink blossoms directly on the trunk and main branches, of which about 20 mature into fruit pods resembling enlarged cantaloupes or cucumbers, 6 to 14 in. long and 2 to 5 in. in diameter and ranging in colour from yellow-orange to dark-red purple. Though these ripen intermittently throughout the year, most ripen in one or two main periods. Four-fifths the world crop is harvested in the period from September to March. The pod is simply cut from the tree and the tough, fibrous hull opened with a machete, after which the 25 to 50 seeds and adhering pulp are scooped out and fermented. The fermenting, whether carried out in a primitive pile on the ground or in a more modern perforated box or tank under cover and high temperature, takes 3 to 12 days, depending on the type of cocoa, and involves draining away the juicy "sweatings" of the pulp and the mixing and stirring of the beans to obtain an even fermentation and to avoid under- or over-fermentation. The germ in the seed is killed by the heat, temperatures as high as 115° F. develop, and the character and flavour of the bean are changed. The exact parts played by heat, enzymes, alcohol and acetic acid are unclear, but the beans become plump and full of moisture; the interior develops an even, reddish-brown tint and a heavy, sharp fragrance. The pulp is easily removed. The beans are then dried, in some cases after washing, by sun or artificially, sometimes on special mats or racks for a few days or weeks, to a water content of about 8%, after which they may be clayed or polished and bagged in burlap for handling. Unwashed, sun-dried beans seem to be preferred; unfermented beans are not desired. The yield on the average is 1 to 2 lb. of cured beans per tree per year, or about 500 lb. per acre. Selected plantings with above-average care will yield much more. There is some evidence of higher yields in alternate years. A major problem, other than that of disease, is how to combine peasant production with more advanced techniques to get higher yields and better quality, preferably at lower cost. Typical costs are extremely difficult to estimate, but West Africa, with its small farmers depending largely on family labour, is the lowest-cost producing area.

Grades and Marketing.—Cocoa is classified in world trade as "base" or "flavour" grades, or as "ordinary" and "fine." In general, these grades relate not to difference in processing but to varieties, of which there are many, the two main groups being Criollo and Forastero. Approximately 10% of world production is of the fine or flavour grades called Criollos, or near Criollos, or high Forastero, marketed especially under the trade names of Arriba, Maracaibo, Caracas and Trinidad Estates and produced mostly in Venezuela, Ecuador, Costa Rica, Surinam, British West Indies, Ceylon and Java. They are largely grown under a plantation system utilizing 100 ac. or more. Forastero types, including subvarieties Trinitario and Amelomado, constitute the base or common grades, marketed as "Accra" from the Gold Coast, of which country they constitute half the export trade and the main source of income for the majority of the people, and "Bahia" from Brazil, as well as "Lagos" and "Sanchez." They usually constitute about 90% of the world's crop, are hardier and give larger yields of medium-quality beans selling for 3 to 15 cents less per pound than the flavour grades. Quality standards for cocoa deteriorated during and after World War II, not only because of increased use of ordinary grades, as flavour grades were available in comparatively smaller amounts, but partly because of relaxed standards under wartime conditions. However, governments intervened in an effort to improve grading and to provide premiums for quality.

The annual crop of cocoa moves into world commerce promptly, partly because local use is not large. Though the beans will keep for a year or more under the best of storage conditions, two or three months is about the limit under the tropical conditions prevailing in the producing areas. The major markets are western Europe and the United States. Four-fifths of the exports go to five countries, and ten countries take 95% of the beans entering world trade. Major changes following World War II were the increased imports of Australia, Spain and Canada and the decrease, perhaps temporary, in imports into Germany and the Netherlands.

Cocoa was bought and sold before World War II essentially on a free but unstable market, involving active middlemen and comparatively wide price fluctuations. Increased output, especially in West Africa, resulted in lower prices and expanded world use but increasingly unsatisfactory conditions for producers during the 1930s. Buying agreements in 1937 among the majority of firms and manufacturers dealing with Gold Coast and Nigerian cocoa soon resulted in a boycott by producers and in a tie-up of marketing. After investigation, the Nowell commission concluded that the agreements should be withdrawn and suggested a plan for reorganizing marketing for those areas, which, however, was precluded by the advent of World War II. Hence, growers of cocoa had no experience with international regulatory agreements; most of the proposals at prewar conferences were in the direction of increasing consumption by advertising and keeping prices as low as possible. There were tight controls over trade during the war: the same price was paid for all West African cocoas during 1942–46, whereas except during periods of short supply the best grade sold for about three times as much as the lowest. Stocks were much reduced at the end of World War II, and production had declined fully one-fifth, not because of war devastation of the producing areas but largely because of a general disruption of the production pattern and as a result of disease. In the early postwar years, world cocoa trade was governed in a general way by the International Emergency Food council. Allocations ended in 1949. The postwar period found both buying and selling concentrated in fewer agencies.

World Net Imports of Cocoa

The government-backed Gold Coast Cocoa Marketing Company, Ltd., and Nigerian Produce Marketing Company, Ltd., sold the West African crops to the British ministry of food and to U.K. merchants and for export. The Instituto de Cacau da Bahia of Brazil and equivalent government-sponsored or government-controlled agencies in other producing countries continued to perform much of the marketing function. Bulk buying was the usual practice in most importing countries in the early postwar period and was only gradually relaxed to be performed by private trade. The U.S. used price controls and processor quotas; decontrol in 1946 had certain far-reaching effects on the world cocoa economy.

Manufacture and Uses.— The United States has the world's largest industry, ordinarily taking as much as 40% of the world's exports and reducing the raw cocoa beans to the several products. There are also major cocoa-manufacturing centres in several western European countries and in Canada, Australia and India.

The beans are cleaned, sometimes washed, and carefully roasted at 275° to 350° F. to develop flavour, colour and aroma and to aid shelling; they are then broken into particles called "nibs" by a rolling or cracking process, and winnowed to remove the fibrous shells. The shells, 10%–14% of the total weight, may be used for cocoa "tea," but usually become cattle feed. The nibs of desired grades and flavours are blended (not more than 25% of flavour grades), then ground to a paste, referred to as cocoa mass or chocolate liquor, which after cooling sets into a hard brown block. Half or more of the mass is a natural fat, cocoa butter, part of which is removed under hydraulic pressure. Various types of chocolate may result depending on the amount of butter remaining, flavouring added and further processing. Unsweetened chocolate or baking chocolate is the ground nib moulded into bars. Sweet drinking chocolate has had sugar added and been somewhat refined; eating chocolate contains more cocoa butter and flavouring. Part of the fat or cocoa butter has been removed from cocoa powder, but it contains from 10% to 20% or more fat and has been treated with an alkali salt which neutralizes the natural acidity of the cocoa and makes it more soluble. All are used in several ways in confectionery, baking, dairy and soft drinks and ice cream industries. Cocoa butter is used in cosmetics and pharmaceuticals. Of all candy flavours, chocolate is generally the most popular (the U.S. industry delivered almost 1,000,000,000 lb. of cocoa products to the armed services during World War II). In addition to the mild stimulating effect caused by theobromine (2.2%) and caffeine (0.1%), cocoa is a concentrated food containing about 40.3% carbohydrates, 26.8% fat, 18.1% protein and 6.3% ash, with small amounts of water and fibre; it provides approximately 2,214 cal. per pound.

Cocoa Production.—Centres of production have changed with time, but commercial cultivation is limited by natural factors to the tropics; practically all development is within 20° north and south of the equator, and the main African belt is less than 10° from the equator. High temperatures, a mean shade temperature of approximately 80° F. with diurnal and seasonal variation of not more than 15° F., appear necessary. The cold limit apparently is an absolute one, whereas temperatures of 100° F. or more, accompanied by high humidity, do no harm. Well-distributed rainfall of at least 50 in. a year (if not irrigated), absence of disease, a considerable population to provide harvest labour, and access to export markets are all factors favouring development. In South America there are large areas apparently suitable for cultivation except for disease. Favourable site factors include a well-drained, porous soil of considerable depth and rich in humus, an altitude of a few hundred feet, protection from strong winds, and some shade.

Centres of production, judged by exports, soon shifted from Mexico to Venezuela; Ecuador was the principal area from about 1850 to 1910, after which Brazil led for a time, only to be surpassed by the rapidly developing West African cocoa belt, which was the leader after 1920 and by the 1950s was producing approximately two-thirds of the expanded world crop of about 1,500,000,000 lb. annually. Production in the Americas has continued at an annual rate of nearly 200,000 tons over many years.

In the early 1950s a trend of incipient decline appeared in the major centres of production, especially those of Africa. The spread of plant disease was a partial explanation. Many major plantings were passing beyond the most productive age period; new plantings apparently did not keep up with loss of trees, partly because of economic competition with other production. Price uncertainties were a factor, having varied approximately tenfold in the 1940s. Plantings in some new or minor areas were expanding, partly with Point Four assistance.

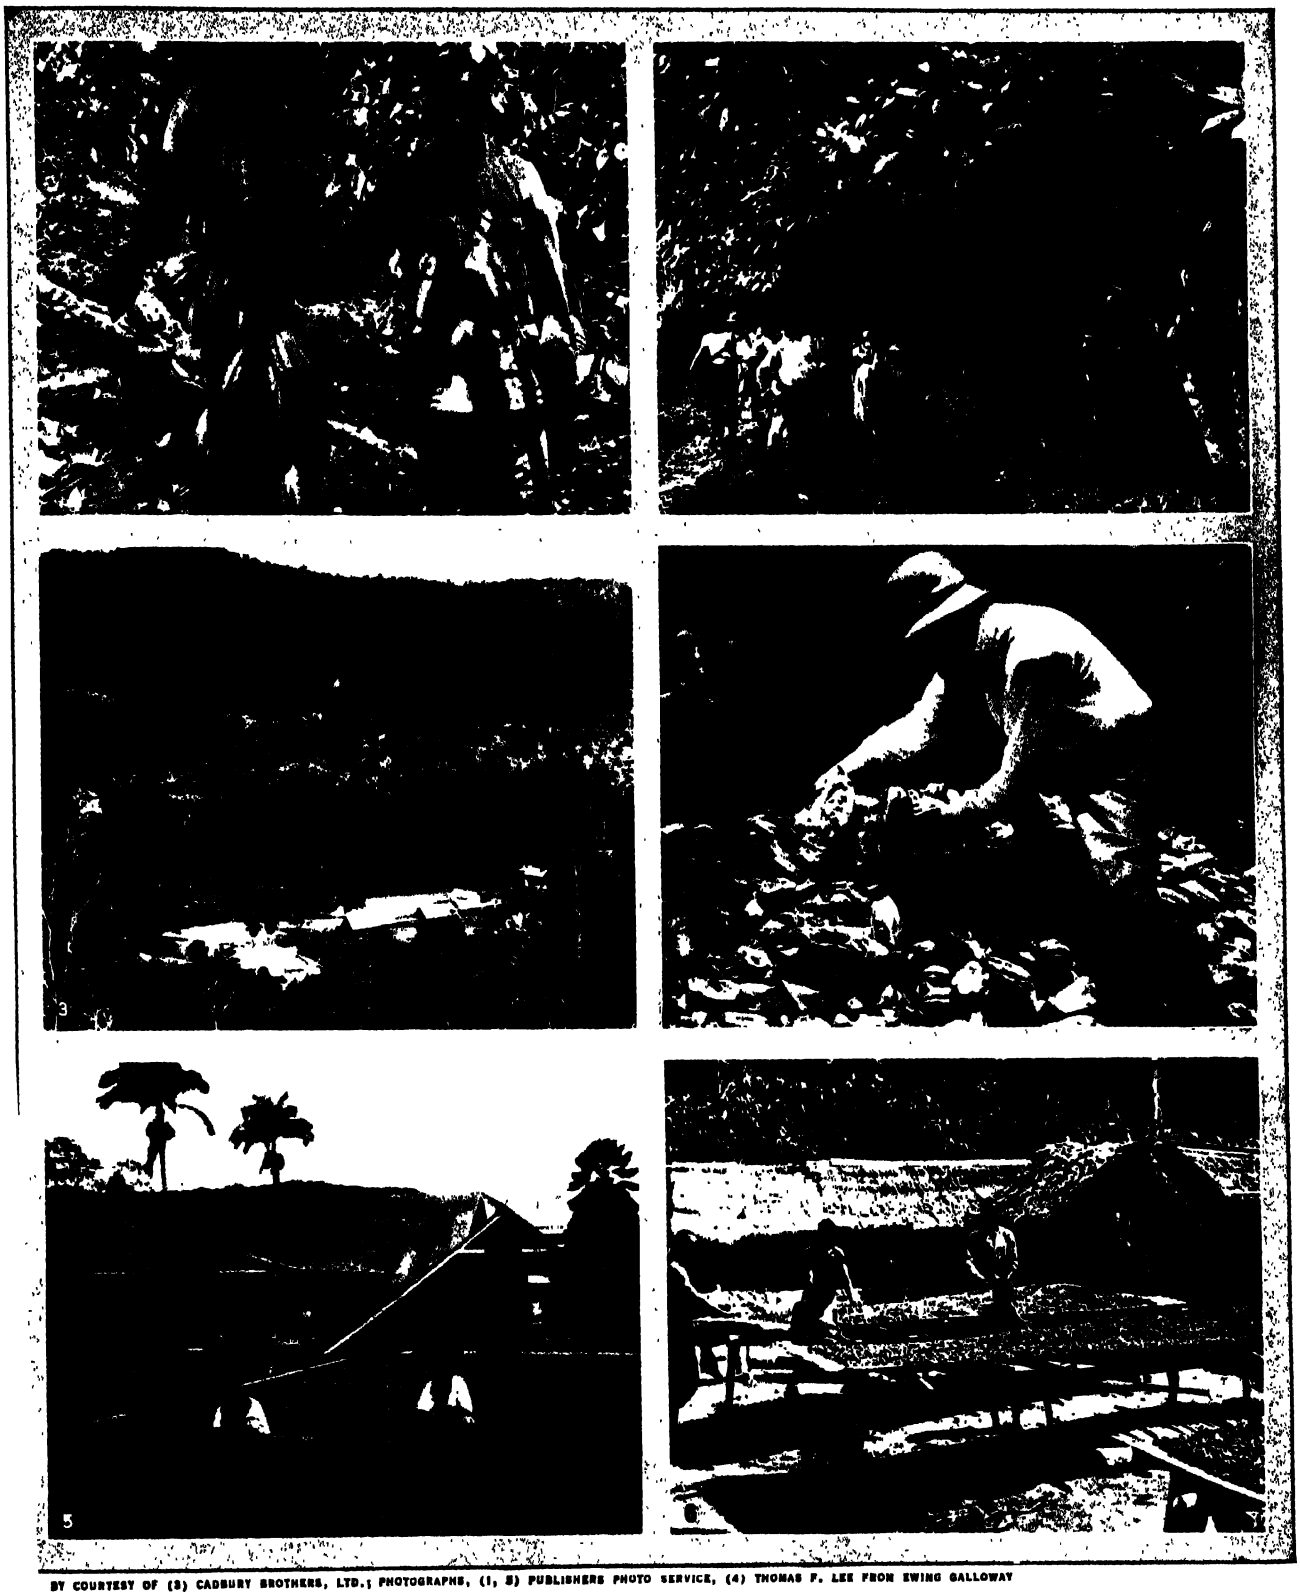
COCOA BUTTER, the pure fat extracted by pressure from the ground and crushed cocoa bean. It is used in the manufacture of confectionery and cosmetics and other toilet preparations. Cocoa butter is sold free from combination with other drugs for treating skin irritations where a pure fat is necessary.

COCO DE MER or DOUBLE COCONUT, a palm, *Lodoicea maldivica,* a native of the Seychelles Islands. The flowers are borne in enormous fleshy spadices, the male and female on distinct plants. The fruits, among the largest known, take ten years to ripen; they have a fleshy and fibrous envelope surrounding a hard, nutlike portion which is generally two-lobed, suggesting a double coconut. The contents of the nut are edible. The empty fruits (after germination of the seed) are found floating in the Indian ocean, and were known long before the palm was discovered.

COCONUCO, a group of South American Indians in south highland Colombia whose language was probably a branch of the Macro-Chibchan phylum. Assimilated by the Spaniards soon after the conquest, their culture is known only from scant historical references. The Coconuco together with the Moguex comprised a dozen or more tribes which resembled their Andean neighbours in carrying on intensive agriculture and having a dense and settled population, federated states and developed warfare. Unlike their neighbours, the Coconuco proper were not cannibals.



See Henri Lehmann, "The Moguex-Coconuco" in *The Andean Civilizations,* 2:969–974, *Handbook of South American Indians,* ed. by Julian H. Steward, Bureau of American Ethnology bulletin 143, (Washington, 1946). (J. H. Sd.)

COCONUT OIL AND CAKE. Coconut oil and coconut cake are derived from the fruit of the coconut palm, *Cocos nucifera.* This tree grows wild on the coasts of all tropical countries and is also extensively cultivated for the many products made by natives from the flower, fruit, leaves and other parts of the plant. Copra, the dried meat of the coconut from which coconut oil is obtained, is the most important commercial product of the coconut palm. Cultivation of the tree for copra is localized principally in the Philippines, India, Ceylon, Indonesia, Malaya and the Pacific Islands.

The fresh kernel of the coconut contains about 50% water and 30% to 40% oil. Therefore, in production of copra the nuts are husked, opened and dried to separate the oil-bearing meat from the shell and to prevent spoilage. The earliest method of drying was to expose the kernels to the air and sun, a practice which is still extensively followed and gives a good quality white copra (sun-dried copra). A more rapid primitive process, adopted particularly in districts where the humidity of the air is excessive, is drying by fire (kiln drying). The kilns, constructed by native labour, consist essentially of a fireplace and a fire pit overlaid with a grid on which the copra is placed. The drying copra is sheltered from the rain by a roof. Such kilns are used generally in the Philippines which supply 50% of the world copra exports. Broken coconut shells, wood and to some extent coconut husks are used as fuel. The copra is deliberately smoked in order to sterilize the partially dried copra, and so modify the extent of self-heating and decomposition during subsequent natural drying in storage in the warehouse of the copra-buyer. The copra does not remain on the kiln for more than two days. During this period the fire in the fire pit is kept going spasmodically. The total length of time during which a fire is actually burning does not exceed six hours. While the quality of copra produced with this form of dryer is not the best, the output of a well-designed kiln can equal the quality of the output of more elaborate dryers, the expense of which places them beyond the means of the small farm owners who produce most of the copra of the Philippines.

Copra of better and more uniform quality is produced by another method—hot air drying—first introduced in India and Samoa. The copra is drawn slowly through a heated tunnel meeting a countercurrent of hot air. The method yields a fine and white copra of higher value than the sun-dried article. Well-dried copra as sold in world commerce contains 4% to 5% moisture. The proportion of oil in such copra ranges from 63% to 70%.

Processing Copra.—Coconut oil is obtained from copra chiefly by pressing in mechanical screw presses. In some areas hydraulic

cage and box presses continue to be employed. Their use, however, is relatively limited, and the world production of coconut oil is largely obtained by use of continuous mechanical screw presses. To obtain a higher oil yield the oil may be extracted with a solvent following a preliminary pressing in screw presses. In either instance before processing the copra is passed through a cleaner which removes sand and trash. It is then passed through a crusher which breaks it into small pieces. The broken copra moves through a magnetic separator which disposes of pieces of iron (bolts, nails, etc.). The material is then ground finely and treated.

Single Pressing.—The finely ground copra is cooked, or dried, in steam-jacketed kettles or compartments to a moisture content of about 1.5%. The meats pass from the driers into continuous mechanical screw presses which consist essentially of a cylinder, or barrel, in which an impelling worm turns and continuously forces the tempered copra through a small terminal orifice. The barrel is composed of a series of rectangular steel bars, separated by spaces to form slots. Pressure and heat of friction release the oil which escapes through the slots of the barrel. Continuous mechanical screw presses may have a vertical and a horizontal pressing barrel, each operated by a separate motor. In the single type the horizontal barrel performs the entire copra-pressing operation. Continuous mechanical screw presses have a capacity of 20–40 tons of copra per 24-hr. day. The oil content in the pressed copra cake varies from 5% to 7%. The cake is ground directly into meal which is placed in bags for marketing. Before passing to the crude oil storage tanks the coconut oil is screened to remove fine particles of ground copra. It is then run through a filter press. The foots from the screening process and the filter press cake are returned to the screw presses for re-pressing.

MECHANICAL SCREW PRESS AND COOKER DRYER USED FOR COPRA CRUSHING

Solvent Extraction.—In Europe and the United States some coconut oil is extracted by means of petroleum solvents (hexane type) from copra which has been prepressed through large continuous mechanical screw presses. These screw presses with a capacity of 25–65 tons per day reduce the oil in copra from 65% to 15% to 20% before the cake is prepared for extraction. The oil-bearing material is treated continuously in a countercurrent flow with solvent until the oil left in the extracted meal has been reduced to .5% to 1%. The solvent is removed from the extracted meal by means of steam-jacketed, agitated conveyers. The solvent from the oil is recovered by distillation and the last traces of solvent are removed by steam distillation of the oil *in vacuo*.

Copra Meal.—The meal from pressed cake contains 21.3% protein on the average and 5% to 7% oil. Solvent extracted cake contains less oil and a proportionately greater amount of protein. Copra meal is valued as a dairy feed. It is also satisfactory as a protein supplement for fattening cattle and lambs.

Coconut Oil.—The oil is colourless to yellowish in appearance and melts at about 74° F. Crude coconut oil has a characteristic coconut odour. The fatty acids of coconut oil possess a lower average molecular weight than those of most other fats. Thus the quick solubility of their sodium salts and the sulphated fatty alcohols derived from coconut fatty acids make coconut oil a highly desirable material for the manufacture of soaps and other detergents.

Edible coconut oil is the product of refining and deodorizing the crude oil to remove free fatty acids and flavours. An important food use of coconut oil arises from its high percentage of lauric acid (48%). The resistance of this saturated fatty acid to the development of rancidity caused by oxidation prompts confectioners and bakers to use refined coconut oil in coatings and fillings for baked goods and candy which may stand for a relatively long time between manufacture and consumption. Prior to World War II coconut oil had extensive use in margarine manufacture in the United States, but later it was largely displaced by domestic oils. Its use in margarine continues undiminished in Europe and other areas. Refined coconut oil is used in the manufacture of shortening and as a cooking fat. (JN. B. G.)

COCONUT PALM (*Cocos nucifera*), best known of the palms and famed as one of the world's most important crop trees, the coconut palm grows to 100 ft. tall. Its slender, leaning, ringed trunk arises from a swollen base, and it is surmounted by a graceful crown of giant, featherlike leaves. About a dozen new leaves appear periodically each year and an equal number of compound flower stalks which, protected by woody spathes, push out from the base of the older leaves. Some 10,000 male flowers and about 30 female flowers appear on each stalk. They mature at different times, assuring cross-pollination. Five-year-old trees start to flower and this process is continuous thereafter. Fruits require a year to ripen; the annual yield per tree may reach 100, but 50 is considered good.

Mature fruits are 12 to 18 in. in length, 6 to 8 in. in diameter, ovoid or ellipsoidal, and with a thick fibrous husk surrounding the familiar single-seeded nut of commerce. A hard shell encloses the insignificant embryo with its abundant endosperm, comprised of both meat and liquid (unsolidified endosperm). The three "eyes" of the coconut shell indicate that three ovarial cavities exist in the flower but only one persists at maturity.

Coconut fruits float readily and have been dispersed widely by ocean currents, and also by man, throughout the tropics. Actually the native home of the coconut palm is unknown, but it probably originated somewhere in Indo-Malaya, where the palm exists in many natural forms. Marco Polo was among the first Europeans to describe coconuts, but the great voyages of discovery such as that of the navigator William Dampier made the species better known. Coconut palms flourish best close to the sea on low-lying areas a few feet above high water where there is circulating ground water and an ample rainfall. The palm sometimes is grown far inland and at altitudes up to 2,000 ft., but in such places production declines.

The coconut attains its greatest marketable value as copra, the dried extracted kernel, or meat, from which coconut oil, the world's ranking vegetable oil, is expressed. It is estimated that 1,000 mature nuts will yield upward of 500 lb. of copra, from which 25 gal. of oil should be obtained. The oil is a white solid substance at ordinary temperatures with a peculiar, rather disagreeable odour. The Philippines and Indonesia lead in copra production, and throughout Polynesia it is the only important export product. Coconut oil has many uses, entering into the manufacture of soaps and shampoos, detergents, edible oils, margarines, vegetable shortenings, synthetic rubber, glycerine, hydraulic brake fluid and plasticizers for safety glass. Copra meal is a

livestock feed and fertilizer while shredded coconut is a familiar item on grocers' shelves. Although the coconut finds greatest commercial utilization in the industrial countries of the western world, its usefulness in its native areas of culture is even greater. Indonesians claim that coconuts have as many uses as there are days in the year, and these are not limited to the oil-yielding nut. Besides the edible kernels and the refreshing and palatable drink obtained from green nuts, the husk yields coir, a fibre highly resistant to salt water and used in the manufacture of ropes, mats, baskets, brushes and brooms. Coir dust, or cocopeat, is a peat substitute of use to horticulture. By wounding the unopened flower stalks one can obtain readily flowing sap yielding toddy, a beverage drunk either fresh or fermented as an intoxicating palm wine. Toddy is a source of sugar as well as alcohol. As in other palms the delicate young bud cut from the top of the tree is eaten as a salad vegetable, palm cabbage; the mature leaves find use in thatching and basketry; and the fibrous decay-resistant trunk is of value not only to the natives who incorporate it in the construction of huts but also as an exported cabinet wood, porcupine wood, so called because of the ebonylike streaks which irregularly mark the red-brown ground colour. (Wr. H. H.)

COCOPA, the Yuman tribe nearest the mouth of the Colorado river, similar in customs to the Yuma and Mohave. The population, originally not far from 3,000, has decreased to about 600, mostly on Mexican soil.

COCYTUS, a tributary of the Acheron (modern Mavropotamo), which flows into the Ionian sea about 20 mi. N. of the Gulf of Arta; identified with a tributary of the Acheron or of the Styx, a river in Hades (*cf.* Virgil's *Aeneid,* vi, 132). The etymology suggested is from *ωκύειν*, to wail, in allusion to the cries of mourners; this is probably a reduplicated form, akin to Skt. *kû,* cry, with intensive kokuyate.

COD, the name given to the typical fish of the family Gadidae of the order Anacanthini, which includes fishes without spinous fin rays, with no duct to the air bladder and with the pelvic fins anterior in position. The pelvic fins are often many-rayed, and the pelvic bones are not directly attached to the pectoral arch, these characters distinguishing the Anacanthini from certain Blennioid fishes of the order Percomorphi, with which they were formerly associated, and indicating their relationship to more primitive orders. The Anacanthini include two principal families: the Macruridae, which are deep-sea fishes without a caudal fin and with the long second dorsal and anal fins continued to the end of the tapering tail; and the Gadidae, in which the caudal fin is composed mainly of dorsal and anal fin rays, the homocercal fin being greatly reduced, an indication that the ancestral form may have been eel-shaped. The Gadidae are marine with the exception of the burbot (*Lota lota*), which is a freshwater fish. They are most abundant in northern seas, where there are several species of great economic importance; *e.g.,* cod, haddock (*q.v.*), whiting (*q.v.*), ling (*q.v.*) and hake (*q.v.*). In warmer seas there are some deep-water forms of no great value, and the hake genus (*Merluccius*) is the only important one represented in both the north and south temperate zones. The flesh of all these fishes is more digestible than nutritious, being poor in fat.

The cod (*Gadus morrhua*), in common with other fishes of the genus *Gadus,* has three dorsal and two anal fins; the upper jaw projects beyond the lower, and there is a barbel at the chin. The colour varies considerably, but is generally olive-green above with darker spots, and white below; the lateral line is white and conspicuous. The cod is found in the North Atlantic and Baltic but not in the Mediterranean; it also occurs in the North Pacific. Generally it lives on the bottom at depths of 10 to 100 fathoms, and feeds on other fishes, such as herring and sand eels, and also on squids, mussels, whelks, etc. The spawning seaon is from January to March; the eggs are minute and are produced in enormous numbers, sometimes 10,000,000 from one female; they float in the water. The young fish attain a length of about two feet in four years; three feet is an average size, but some grow to more than five feet long and weigh more than 100 lb. The cod is the object of extensive fisheries by line and trawl on the Newfoundland banks, off Iceland and in the North sea. The greater part of the catch is split, salted and dried; the livers are used for the preparation of cod-liver oil, and the roes are sent to France to be used as groundbait in the sardine fishery; isinglass is made from the air bladder. (C. T. R.)

C.O.D.: *see* Cash on Delivery.

CODA, in music, a term for a passage which brings a movement or a separate piece to a conclusion. (Ital. for "tail"; from the Lat. *cauda.*) This developed from the simple chords of a cadence into what is often an elaborate and important feature of a composition on a large scale. Beethoven raised the coda to a feature of the highest importance. A codetta (diminutive of coda) is merely a small coda, employed to round off not a complete work but an intermediate section of it.

CODDE, PIETER (1599–1678), Dutch painter of the school of Haarlem, was born on Dec. 11, 1599, at Amsterdam. He was probably a pupil of Franz Hals, whose painting of the Doelen of "Captain Reaels," left unfinished in 1637, he was asked to complete. He was active as a genre painter at Amsterdam and Leyden, and he liked to represent ladies and gentlemen dancing (Sievers' collection, Dorpat, 1627; Mauritshuis, The Hague, 1636; Academy in Vienna, 1633), or scenes with soldiery (Mauritshuis, The Hague, 1628; Dresden gallery, 1628). He also executed some small portraits (National gallery, London). He died at Amsterdam on Oct. 12, 1678.

CODDINGTON, WILLIAM (1601–1678), one of the founders of Rhode Island, was born in Lincolnshire, Eng. He was sent out to the colony at Massachusetts bay as a magistrate, arriving at Salem on June 12, 1630. He was for some time treasurer of the colony, and is said to have built the first brick house in Boston. He supported the cause of Anne Hutchinson, the antinomian, and when she was exiled he left, in 1638, for Rhode Island. His name appears first in the covenant of the settlers (*see* Rhode Island). When Portsmouth and Newport were united (1640) Coddington was appointed the first governor, and he was president of the colony in 1648–49. During his year of office he tried, without success, to secure the inclusion of Rhode Island in the confederacy of the United Colonies of New England. He was again governor in 1674–76. He died on Nov. 1, 1678.

CODE. By codification is now meant "an orderly and authoritative statement of the leading rules of law on a given subject" (Ilbert), but the early collections of laws known as codes were of a different character.

> The ancient codes [wrote Maine] were doubtless originally suggested by the discovery and diffusion of the art of writing. . . . Their value did not consist in any approach to symmetrical classification, or to terseness and clearness of expression, but in their publicity. . . . They mingled up religious, civil and merely moral ordinances without any regard to differences in their essential character.

The oldest-known code is that of Hammurabi, for which *see* Babylonian Law. In ancient India the laws applying to the Hindu community of the time were codified.

Roman law began with the Twelve Tables—a primitive code—and culminated in the code of Justinian, which was given the force of law in A.D. 534. (*See* Roman Law.) "Though the name was invented and used in a somewhat different sense by the Romans, the thing is of far more modern origin. . . . The Romans never advanced beyond a digest," whereas, properly, "a code is a digest of which every title has been consolidated" (Holland). The peoples who overran the Roman empire made collections of rules of law; *e.g.,* the law of the Salian Franks and other Frankish laws. (*See* Germanic Laws, Early; Salic Law.)

The Rhodian sea law was a collection of rules of maritime law, mainly derived from local customs, originally put together between A.D. 600 and 800. Collections of maritime usages and customs, drawn up for the use of merchants and lawyers, acquired in the 14th and 15th centuries great authority throughout Europe. Some were compiled in Mediterranean ports, and others for the use of merchants trading in the north of Europe. There were, for instance, the laws of Oleron (an island near Bordeaux), the laws of Wisby in Gothland, the *Consolato del Mare* (a collection of the maritime laws of Barcelona), the Oak Book of Southampton and other collections.

Mediaeval France was divided into *pays de droit écrit* and

pays de droit coutumier. In the former, feudal rules overlay the Roman law; in the latter, customs differed in each province, county and municipality. Despite the promulgation of a series of ordinances, an extraordinary diversity of laws continued until, after the Revolution, they were superseded by the Codes Napoléon which were then drawn up. (*See* CODE NAPOLÉON.)

Several European countries have modelled their codes upon those prepared in France under Napoleon, but in Germany events followed an independent course. From 1495 the German common law was a modified form of Roman law, but it was subject to modification by local customs, codes and state laws. Prussian common law was codified in 1794, this step being to some extent an anticipation of the idea of the French codes. With the formation of the North German confederation in 1866 federal legislation began and a general commercial code was enacted. In 1874 (three years after the formation of the German empire) preparations for general codification commenced. After many revisions the German civil code came into force in 1900 and along with it a remodelled commercial code.

The steps taken later toward the codification of law, not only in England but also elsewhere, originated in the reforming energy of Jeremy Bentham (1748–1832). Bentham's philosophy of law did not take sufficiently into account the march of events either in the past or in the future. He lived before it had become the practice to work by methods which include historical research, and he did not sufficiently appreciate that there is no finality in law, that it must be revised from time to time as circumstances change. Nevertheless, in this matter he was a great moving spirit.

What he did was to set up an ideal towards which legislation should tend, an ideal which has been materially modified by subsequent reflection and experience, but which has profoundly influenced the thought and action of lawyers and legislators since his time. He has not shown the necessity, but he has shown the utility, of codification [Ilbert].

In British India the codification of the law may be attributed directly to the influence of Bentham exercised through James Mill and Macaulay. The penal code became law in 1860 and was followed by two codes dealing with procedure, and, in course of time, by a number of others on various branches of the law.

Following earlier attempts made in England to improve the form of the law, a number of statute law commissions were appointed during the earlier part of the Victorian period. Various reforms resulted, and many consolidation acts were passed, dealing with, *e.g.*, the customs, public health, merchant shipping and so forth. With lapse of time the need for reconsolidation, so as to incorporate later amendments, manifested itself, and from the beginning the process in most instances fell short of full codification because consolidation covered only statutory provisions and did not extend to common-law rules. Later some measures were passed codifying both the statute and the common law relating to particular subjects; *e.g.*, the Bills of Exchange act, 1882, the Partnership act, 1890, the Sale of Goods act, 1893, and the Marine Insurance act, 1906.

English law is the basis of the law in force in most of the states of the United States, an exception being Louisiana, where a civil code based on the Code Napoléon was adopted in 1808. Much codification of law was carried out in many of the states during the latter part of the 19th century, the first move in this direction being the adoption of a code of civil procedure by the state of New York in 1848. The laws of the South American republics for the most part were codified.

In Egypt a series of codes came into force in 1875. Japanese law was codified on the basis of an investigation into the laws of European countries which extended over the greater part of the last quarter of the 19th century. The civil code (which came to be the main foundation of the Japanese legal system) and the commercial code were largely modelled on German law.

International Codes.—Besides the codification of national laws something was done toward codifying rules of law regulating the relations between states and between the subjects of different states. These rules are commonly referred to as those of public and private international law, respectively. The advisory committee of jurists which met at The Hague, Neth., in 1920 to draft the plan for the Permanent Court of International Justice recommended that, in continuation of The Hague Conferences of 1899 and 1907, steps should be taken to bring about the restatement of the established rules of international law and the formulation of additional rules. Pursuant to this the League of Nations in 1924 appointed a committee of experts for the progressive codification of international law composed of jurists from 17 countries.

This committee reported in 1927 and continued its work thereafter. Pursuant to its recommendations a first codification conference was held at The Hague in 1930 to consider (1) nationality, (2) territorial waters and (3) responsibility of states for damage done in their territory to the person or property of foreigners.

Proposals for codification of international law aroused much interest in America. In 1906 the third Pan-American conference adopted a convention under which codes of private and public international law were to be prepared. At later meetings of the Pan-American conference (including that at Havana in 1928) further discussion of projects of conventions took place.

On the subjects selected for the first codification conference of 1930 as well as other possible subjects for the work of codification the progress resulted in large measure from unofficial spade work done in the past by the Institute of International Law and the International Law association. These, after 1873, were busy with the problems to which governments later turned their attention. After 1896 their activities were supplemented by those of the Comité Maritime International and after 1905 by those of the American Society of International Law.

The official movements above referred to did not bring about any actual codification of rules of law of international application, but in certain directions codification or unification was accomplished. In the absence of an international legislature no actual codification by means of international legislation is possible, but an equivalent result was produced in relation to certain matters by national legislation being passed in conformity with an international convention, or (in some commercial matters especially) unification was achieved by the formulation and common adoption of standard clauses for incorporation by reference in contracts. In this way the International Law association brought about the unification of some of the rules of law and practice relating to general average. International rules drawn up for this purpose and incorporated by reference in shipping documents are known as the York-Antwerp rules. The first rules adopted were those dated 1877. They were revised in 1890 and in 1924 were again revised and expanded into what is practically a code of general average (*see* AVERAGE). On the other hand the regulations for the prevention of collisions at sea, having been adopted by all maritime nations, are an example of standardized national legislation. Working after this method, the Comité Maritime International drafted international conventions, some of which were carried into effect by national legislation, while others awaited further action by maritime states. In the United States steps to standardize certain commercial laws throughout the different states of the union brought about the passing of uniform acts relating to negotiable instruments, sale of goods, bills of lading, warehouse receipts, etc.

(S. D. C.)

CODEINE occurs naturally in opium, being one of the alkaloids (*q.v.*) of the phenanthrene group and a derivative of morphine (*q.v.*), retaining in a modified form the characteristic physiological action of the latter. It crystallizes with one molecule of water, in large translucent prisms, melts at 155° C. and has a specific rotation $[\alpha]-137.7°$. It behaves as a monoacidic base, forming salts of which the sulphate and the phosphate are those most frequently used in medicine. It is commonly used orally and hypodermically to relieve pain and spasm and as a sedative.

(F. L. A.)

CODE NAPOLÉON, the first code of the French civil law, known at first as the Code Civil des Français, was promulgated in its entirety by a law of 30 Ventose year XII (March 21, 1804).

On Sept. 3, 1807, it received the official name of Code Napoléon, although the part that Napoleon took in framing it was not very important. A law of 1818 restored to it its former name, but a decree of March 27, 1852, re-established the title of Code Napoléon. Since Sept. 4, 1870, the laws have quoted it only under the name of the Code Civil.

Never has a work of legislation been more national in the exact sense of the word. Desired for centuries by the France of the *ancien régime*, and demanded by the *cahiers* of 1789, this "code of civil laws common to the whole realm" was promised by the constitution of 1791. However, the two first assemblies of the Revolution were able to prepare only a few fragments of it. The preparation of a coherent plan began with the Convention. The *ancien régime* had collected and adjusted some of the material. There was, on the one hand, a vast juridical literature which, by eliminating differences of detail, had disengaged from the various French "customs" the essential part which they had in common, under the name of "common customary law"; on the other hand, the Roman law current in France had in like manner undergone a process of simplification in numerous works, the chief of which was that of Domat; while certain parts had already been codified on the Grandes Ordonnances, which were the work of D'Aguesseau. This legacy from the past, which it was desired to preserve within reason, had to be combined and blended with the laws of the Revolution, which had wrought radical reforms in the conditions affecting the individual, the tenure of real property, the order of inheritance and the system of mortgages. Cambacérès, as the representative of a commission of the Convention, brought forward two successive schemes for the Code Civil. As a member of one of the councils, he drew up a third under the Directory, and these projected forms came in turn nearer and nearer to what was to be the ultimate form of the code. So great was the interest centred in this work that the law of 19 Brumaire year VIII, which, in ratification of the previous day's coup d'état, nominated provisional consuls and two legislative commissions, gave injunctions to the latter to draw up a scheme for the Code Civil. This was done in part by one of the members, Jacqueminot, and finally under the constitution of the year VIII the completion of the work was taken in hand. The legislative machinery established by this constitution, defective as it was in other respects, was eminently suited for this task. Indeed, all projected laws emanated from the government and were prepared by the newly established council of state, which was so well recruited that it easily furnished qualified men, mostly veterans of the Revolution, to prepare the final scheme. The council of state naturally possessed in its legislative section and its general assembly bodies both competent and sufficiently limited to discuss the texts efficiently. The *corps législatif* had not the right of amendment, so could not disturb the harmony of the scheme. It was in the discussions of the general assembly of the council of state that Napoleon took part, in 97 cases out of 102, in the capacity of chairman, but, interesting as his observations occasionally are, he cannot be considered as a serious collaborator in this great work.

Those responsible for the scheme were in the main very successful in their work; they generally succeeded in fusing the two elements which they had to deal with, namely ancient French law, and that of the Revolution. The point in which their work is comparatively weak is the system of hypothec (*q.v.*), because they did not succeed in steering a middle course between two opposite systems, and the law of March 23, 1855 (*sur la transcription en matière hypothécaire*), was necessary to make good the deficiency. A fault frequently found with the Code Civil is that its general divisions show a lack of logic and method, but the division is practically that of the *Institutes* of Justinian and is about as good as any other: persons, things, inheritance, contracts and obligations, and finally, in place of actions, which have no importance for French law except from the point of view of procedure, privileges and hypothecs, as in the ancient *coutumes* of France, and prescription. It is, *mutatis mutandis*, practically the same division as that of Blackstone's *Commentaries*.

In later years other objections were expressed; serious omissions were pointed out in the code; it does not give to personal property the importance which it acquired in the course of the 19th century; it makes no provision for dealing with the legal relations between employers and employed which modern complex undertakings involve; it does not treat of life insurance, etc. But this only proves that it could not foretell the future, for most of these questions are concerned with economic phenomena and social relations which did not exist at the time when it was framed. The code needed revising and completing, and this was carried out by degrees by means of numerous important laws. In 1904, after the celebration of the centenary of the Code Civil, an extraparliamentary commission was nominated to prepare a revision of it. (J. P. E.)

Dissemination of the Code.—The influence of the Code Civil has been very great, not only in France but also abroad. It should be remembered that when the Revolution broke out France had for a century and a half held, almost without a rival, the leading place among the nations of the world. Its language was well on the way to succeeding Latin as the common speech of civilized men; its literature, its arts, the fascination of its culture, the splendour of its capital city, the devotion of its missionaries, held all mankind spellbound. Yet its law had no admirers or imitators in other countries. Few foreigners thought it worth while to study France's meagre legal literature; few students from abroad sought admission to its law schools. The Revolution and the empire, by the alarm which they excited and by the spirit of nationalism which they stimulated in other countries, went far to forfeit for France the pre-eminence which it had won and was winning by peaceful penetration. But the code saved the situation; and ever since its promulgation (March 21, 1804), France has exerted an incomparable influence upon the institutions and legal culture of the civilized world. Indeed, until the promulgation of the German civil code (Aug. 24, 1896) the Code Napoléon was without a competitor as a model for law reformers throughout all parts of the world outside the British empire and the United States. In the absence of an English code, the English common law has, in spite of the great place which it occupies, found acceptance in no country outside the circle of those which, by reason of conquest or of colonization, possess English-speaking rulers. The 19th century was pre-eminently an age of nation-making. In Europe it saw the creation or the unification of Germany, Italy, Belgium, Rumania, Bulgaria and Greece; on the American continent it saw the Spanish and Portuguese colonies transformed into 15 new nations; and in the east it witnessed Japan, Thailand, Turkey and Egypt attempting with greater or less success to grasp the secret of European pre-eminence. Of these 25 nations almost all sought to mark their succession to political maturity, and to proclaim their adherence to the European world, by a general revision and codification of their laws; and in most cases the model followed was that furnished by the Code Napoléon. The code was attractive in form; it was written in French; it was, or seemed to be, easy to understand; it bore the name of the greatest man of the age; it claimed to be catholic, rational, imperial and universal; it was secular without being irreligious and democratic without being revolutionary. In short, according to the ideas of 19th-century liberalism, it set forth in chapter and verse the fundamental articles of the social contract. Nor did the code have to rely upon its intrinsic merits alone. The reorganization of the French educational system, and particularly of the university, which constituted one of Napoleon's principal achievements, created law schools which in their turn produced an imposing literature of exposition and commentary on the code. This literature was an important factor in promoting the adoption and assimilation of the code by other countries.

The Napoleonic Empire.—When first promulgated in 1804, the French code came automatically into force in all those countries which were at that time subject to the empire. These were Belgium, Luxemburg, the Palatinate, those parts of Rhenish Prussia and Hesse-Darmstadt which were situated on the left bank of the Rhine, the territory of Geneva, Savoy, Piedmont and the duchies of Parma and Piacenza. Napoleon subsequently promulgated the code in the following countries as they were successively conquered: Italy (by decree of March 30, 1806), Holland (Oct. 18, 1810), the Hanseatic departments (*senatus-consultum* of Dec. 13, 1810) and the grand duchy of Berg (decree of Dec. 17, 1811). The following countries adopted the code *proprio motu*, though doubtless under some pressure, before the fall of the empire: Westphalia, Hanover, the grand duchies of Baden, Frankfurt, Nassau and Warsaw, several of the Swiss cantons, the free city of Danzig, the Illyrian provinces and the kingdom of Naples.

The blows delivered at Leipzig (1813) and Waterloo (1815) to French prestige gave a check, but only for a short time, to the dissemination of the code. In many parts of Italy, for example, the restoration governments revived the old laws; but they were speedily compelled to recognize that the clock could not be put back in so violent a fashion and to revert to codes on the French model. The code of the two Sicilies (1819), the code of Parma, promulgated by the former empress, Marie Louise, in 1820, the important Sardinian or "Albertine" code promulgated for Piedmont in 1848, and the civil code of Este (1851) all bear the mark of French influence. These essays in legislation led up to and were replaced by the general civil code for the new kingdom of Italy which came into force on Jan. 1, 1866. The similarity of this code to the French code is particularly marked in all those parts in which both remain closest to Roman law, *i.e.*, in the sections treating of obligations and real rights. The degree of this similarity may be judged by the fact that a committee composed of French and Italian jurists prepared drafts with a view to a uniform revision of those parts of the two codes which related to the law of obligations.

Europe After Waterloo.—The restitution, after Waterloo, of their possessions on the left bank of the Rhine to Prussia and the German states was not followed by the abandonment of the French code, which remained in force until replaced in 1900 by the general code for the German empire. In Baden the Code Napoléon was transmuted and preserved, without substantial change, in the *Badisches Landrecht* and in this form had a similarly long lease of life. The code not only remained in force in that country, but was the subject of influential exposition. The *Commentary* of Zachariae, a Heidelberg professor, published in 1808 was the first general treatise on the code in any language. Not only was it destined to reappear in numerous successive editions in German, but it served as the basis for the French *Commentary* of Aubry and Rau, of which the edition completed in 1922 still bore on the title page "*d'après la méthode de Zachariae.*" Puchelt's *Zeitschrift für französisches Civilrecht*, founded in 1870 and published at Mannheim, continued to appear till early in the 20th century.

Egypt.—Egypt offers an example of the reception not only of the

Code Civil but of its four companion codes by a people totally alien to Europe in all cultural traditions. When, in 1874, the Egyptian government obtained the consent of the powers to the institution of the mixed tribunals, it was agreed without debate that the only possible law with which to equip them was that of the French code. The Code Civil, as adapted for application by the new tribunals, was shorn of all matters relating to personal status and to the effects on property of marriage and death. In 1883, the year following the British occupation, the French codes were extended, in a form almost identical with that adopted by the mixed courts, to the newly organized native jurisdiction. The result of this twofold "reception" of the French codes was that Egypt looked to French textbooks, to French judicial decisions and in a large measure to French professors for the progressive elucidation of the law. It was largely for this reason that in spite of the British occupation the social and cultural influence of France remained supreme in that country. It has been remarked that proposals for innovation made by English advisers met with opposition as often on the ground that they offended against the principles of French law as on the ground that they trespassed against the sacred law of Islam.

Japan.—The course of events in Japan was different and even more instructive. One of the first acts of the restoration government, as early as 1870, was to cause the Code Napoléon to be translated and to send for French jurists to supervise the administration of justice and to organize legal education. Though not promulgated as law, the French code in this way and in the absence of any serious rival, either indigenous or foreign, acquired great authority from the beginning of the new regime. In 1880 there was published a draft civil code, prepared by Boissonade, a member of the French legal mission. This code, though it, too, was not promulgated as law, exercised for 16 years as great an influence in the country as if it had been legally in force, and was treated by the judges as a statement of the principles of natural reason and equity. Meanwhile, concurrently with the academic teaching of French law, provision had been made by the Japanese government for instruction in Anglo-U.S. law at the University of Tokyo. In 1892 Boissonade's code was on the eve of being put into force, when the diet voted that it should be submitted to a further revision. This decision appears to have resulted from dissensions between the French and English schools of legal thought. The result was that when the revised code was finally promulgated in 1896 it was found to be neither English nor French but German in inspiration.

Competition of German Civil Code.—This *dénouement* was symbolic. The German civil code, published in its final form in 1895, was the first serious rival which Napoleon's code had had to encounter. As compared with its French predecessor, the German code had the advantage derived from a century of progress in legal science; it was a more carefully thought out piece of work; it was greatly superior in arrangement; it distinguished more clearly between substance and accident, between principle and application; in short, it was a more scientific piece of work. There are strong indications that it may now be taken to have replaced the French code as the model for future essays in codification. The Swiss civil code, for example, dated Dec. 10, 1907, was largely modelled on the German code, though in form it was shorter and simpler. The Turkish republic adopted it, almost without alteration, as the civil code of Turkey. (M. S. A.)

CODES AND CIPHERS (CRYPTOLOGY), general terms designating the methods or the paraphernalia employed in secret communications or involved in the science of cryptology (from Gr. *kryptos*, "hidden," and *logos*, "word"). Because of the growth of governments, the expansion of commerce and especially the remarkable progress made in communications-electronics technology, cryptology has come to play a very important role in governmental communications, especially diplomatic and military. It also plays a minor role in commercial, industrial and banking communications. Among the more uncommon uses of cryptology are those in connection with attempts to establish authorship in cases where that has been brought into question, as, for example, that of the Shakespeare plays.

In its early stages cryptology was concerned almost exclusively with secrecy in written communications and this article will be restricted very largely thereto, but the science has developed to the stage where it deals not only with enciphered writing (cryptograms) but also with other mediums of cryptocommunication, such as enciphered telephony (ciphony) and enciphered facsimile (cifax) transmissions.

Cryptology embraces the twin or complementary sciences of signal security and signal intelligence. The former deals with all the means and methods of protecting one's own signals against interception and reading or utilization by unauthorized persons generally referred to as "the enemy." The latter deals with all the means and methods employed in acquiring information or intelligence by intercepting and solving the enemy's cryptosignals or nullifying his signal security so that the signals or information derived from them can be used against him.

Signal Security.—The principal components of this phase of cryptology are: (1) physical and personnel security; (2) transmission security; and (3) cryptosecurity. The first deals with the precautions and measures taken to assure that the physical arrangements and the facilities or procedures for safeguarding the paraphernalia or cryptomaterials used, *i.e.*, the codes, ciphers, key lists, etc., are adequate for the purpose and that the personnel employed in operating the codes and ciphers or cipher machines are trustworthy. The second component deals with the means, methods and procedures for assuring that no information is inadvertently disclosed either by indiscretions of operators or by faults in the transmitting or receiving apparatus which may assist in the solution of the transmissions. The third component, cryptosecurity, which deals with the technical adequacy of the cryptosystems employed, is usually of greater interest and deserves more extensive treatment than the other two. In an article of this nature it is possible only to deal briefly with cryptography (from Gr. *kryptos*, "hidden," and *graphein*, "to write"), it being understood that many of the cryptoprinciples employed for the protection of written communications, or signals representing them, can also be used in protecting or disguising other types of cryptosignalling; *e.g.*, ciphony and cifax. Cryptography deals with the processes, methods or means involved in preparing cryptograms, that is, messages or writings which are intended to be incomprehensible except to those who legitimately possess the proper special paraphernalia and the keys for those cryptograms and know how to use them in order to reproduce the original plain text of the messages. These processes are usually accomplished by means of cryptosystems employing codes or ciphers. The process of converting a plain-text message into a cryptogram is called enciphering (or encoding); that of reconverting the cryptogram back into its intelligible form, when done by a legitimate or authorized communicator, *i.e.*, one who legitimately holds the paraphernalia and the key, is called deciphering (or decoding).

Although in theory no sharp line of demarcation can be drawn between code systems and cipher systems, in modern practice the technical differences between them are sufficiently marked to warrant their being treated as separate categories of methods. Some authors include as a third and separate category the extensive but much less important one containing the so-called "concealment systems," which are sometimes employed to hide an internal or secret message within an external or apparently innocent piece of writing with a view to avoiding arousing suspicion in the minds of persons not privy to the secret, or to eluding censorship in wartime. In such systems the message or its elements are hidden or disguised by any one of hundreds of different means and methods, including such mediums as secret or invisible inks, microscopic writing, etc., but none of these concealment systems or devices will even be mentioned again herein. It is convenient to consider cipher systems first, then code systems, with the understanding that only a very few of the limited number of systems suitable for serious usage can here be outlined.

Cipher Systems.—In general, cipher systems involve a cryptographic treatment of textual units of constant and equal length, usually single letters, sometimes pairs, rarely sets of three letters, these textual units being treated as symbols without reference to their identities as component parts of words, phrases and sentences. Every practical cipher system must combine (1) a set of rules, processes or steps constituting the basic cryptographic method of treatment or procedure, called the general system, which is agreed upon in advance by the communicators and which is constant in character, with (2) a specific key which is variable in character. In enciphering plain text, the specific key, which may consist of a number or a series of numbers or a word, phrase, sentence, etc., controls the steps under the general system and determines the specific nature or exact composition of the cipher

message produced; in decipherment the specific key similarly controls the steps and determines what the deciphered text will be. When all operations are performed correctly, the two plain texts (before and after the cryptography) should be identical or nearly so, save for minor differences arising from errors in their encipherment and transmission or in their reception and decipherment. The general system should be such that even if it is known to the enemy no properly enciphered message can be read by him unless he also knows the specific key or keys applicable to that message.

Despite a great diversity in the external appearance and internal constitution of ciphers, there are only two basic classes of systems—transposition and substitution. (Concealment ciphers are excluded from the discussion.) A transposition cipher involves a rearrangement or change in the sequence of the letters of the plain-text message without any change in their identity; a substitution cipher involves a replacement of the plain-text letters by other letters (or by other symbols) without any change in their sequence. The two systems may be combined in a single cryptosystem.

The majority of transposition systems involve inscribing the letters of the plain text in a geometrical design called a matrix, beginning at a prearranged initial point and following a prescribed route, and then transcribing the letters from the matrix, beginning at another prearranged initial point and following another prescribed route. The matrix may take the form of a rectangle, trapezoid, octagon, triangle, etc., but systems in which the specific keys consist solely in keeping the matrices, the initial points and the routes secret are not often now employed because of their limited variability and, therefore, their relatively low degree of security. In this same class also fall systems which employ perforated cardboard matrices called grilles, descriptions of which will be found in most of the older books on cryptography. The transposition system most commonly used in practice is that designated as columnar transposition, wherein the transposition matrix takes the form of a simple rectangular figure the dimensions of which are determined in each instance jointly by the length of the individual message and the length of the specific key. An example is shown in fig. 1.

Key

Cryptogram

ENEET FTARR CYETE AINLU UIPTR DUHDR LO

Fig. 1.—An example of simple columnar transposition. The numerical key is derived by numbering the letters of the keyword ("telegraph") in accordance with their relative order of appearance in the ordinary alphabet, repeated letters, if present in the key, being numbered in sequence from left to right. The message is written in the normal manner from left to right in successive horizontal lines underneath the key, forming a "rectangle" of columns of letters. These letters are then transcribed in regular groups of five from the rectangle by reading down the columns, taking the latter in the sequence indicated by the key numbers. The last line of the rectangle may be completely filled with letters, nonsignificants being added if necessary; but the security of the method is considerably increased if the last line shows one or more blank spaces, as in this example.

In the foregoing case the letters undergo a single transposition; in cases involving double transposition, that is, wherein the letters undergo two successive transpositions, the security of the cryptograms is very greatly increased, provided the methods selected are such as will effectively disarrange individual letters and not merely whole columns or rows. A practical system of double transposition is illustrated in fig. 2. The principal advantages of transposition systems lie in their comparative simplicity, speed of operation and, in some cases, their high degree of security; but despite these important considerations they do not at the present time play a prominent role in practical cryptography.

Substitution systems involve the use of conventional or cipher alphabets composed of two juxtaposed sequences, one (either expressed or implied) corresponding to the letters of the ordinary alphabet (*a*, *b*, *c* . . . *x*, *y*, *z*), the other containing their respective

Fig. 2.—An example of true double transposition. The cipher letters resulting from the first transposition rectangle (a) are written under the key of the second transposition rectangle (b) just as though they constituted plain-text, that is, from left to right, in successive horizontal rows. The final transposition is then performed in exactly the same manner as in fig. 1, yielding five-letter groups. The two rectangles may be based upon the same keyword, as in this example, or upon wholly different keywords.

cipher equivalents. The complexity of a substitution system usually depends upon three factors: (1) the specific composition of the cipher alphabet or alphabets employed; (2) the number of them involved in a single cryptogram; and (3) the specific manner in which they are used. As to their composition, cipher alphabets are of various types and are known under various names, such as standard, direct, reversed, systematically mixed, key-word mixed, random mixed, reciprocal, etc., all having reference to the nature of the two sequences composing them, the interrelations existing among them internally or externally, etc. The most important factor in connection with a cipher alphabet is whether its two sequences, regardless of their composition, are known or unknown to the enemy; for, if known, any conventional or disarranged alphabet may be handled with the same facility as the normal alphabet. As to the number of alphabets involved in it, a cryptogram is either monoalphabetic, involving a single cipher alphabet, or polyalphabetic, involving two or more alphabets. In essence the difference between the two types lies in the fact that in the former the equivalence between plain-text and cipher letters is invariant, *i.e.*, the equivalence is of a constant or invariable nature throughout the cryptogram, whereas in the latter it is of a changing or variable nature, controlled by the key. With regard to secrecy, the third condition mentioned above, namely, the specific manner in which the various cipher alphabets are employed, is the most important in determining the degree of security or resistance the cryptogram will have against cryptanalysis, as explained below.

Monoalphabetic substitution is usually uniliteral; *i.e.*, each letter of the plain text is replaced by a single character. Cases of biliteral, triliteral, etc., substitution are sometimes encountered; an example using biliteral equivalents is shown in fig. 3. No matter how many characters are in the groups composing the cipher equivalents for plain-text letters, if the groups are always the same for each letter, the substitution system is still monoalphabetic and the cipher can be treated as such.

Polyalphabetic systems are often referred to as double-key systems and, as noted above, employ two or more cipher alphabets in the encipherment of single dispatches. In a given system the

Cryptogram

CAABA CBAED CAABB BBAAE etc.

Fig. 3.—An example of biliteral, monoalphabetic substitution. A keyword alphabet of 25 letters (I serving also for J) is written in a square 5 x 5. (In this case the alphabet is based upon the word "telegraph.)" The letters (A,B,C,D, E) at the side and top of the square, taken in pairs, can then be used to represent the letters within the square. Thus, D = CA, E = AB, etc. The letters at the side of the square may be the same as or different from those at the top; in both cases keywords, identical or different, may be used instead of the letters A,B,C,D,E.

cipher alphabets may be entirely independent or they may be interrelated. In the simplest case of interrelated alphabets, that resulting from juxtaposing, at all points of coincidence, two primary sequences which are normal sequences proceeding in the same direction ($a, b, c \ldots x, y, z$), the secondary cipher alphabets are called standard alphabets; these when successively tabulated yield a symmetrical or square table (fig. 4) which is generally referred to in the literature as a Vigenère table, a quadricular table, etc.

Such a table may be used in several ways. The most common method employs the top row of letters as the plain-text sequence and the successive horizontal rows as the cipher sequences, each of which may be designated by its initial letter. Thus, the fourth or D alphabet is the one in which plain text A is represented by cipher D; *i.e.*, $A_p = D_c$, $B_p = E_c$, etc. In the ninth or I alphabet, $A_p = I_c$, $B_p = J_c$, etc. Therefore, when several such alphabets are to be employed, the letters of a key word can serve to indicate the number, identity and sequence of the cipher alphabets to be used consecutively in the cryptographic operations.

This type of cryptogram is usually referred to as the Vigenère cipher or as *le chiffre indéchiffrable*, although Blaise de Vigenère never claimed that he invented the table or the system; he was merely among the first to describe it (*see* below).

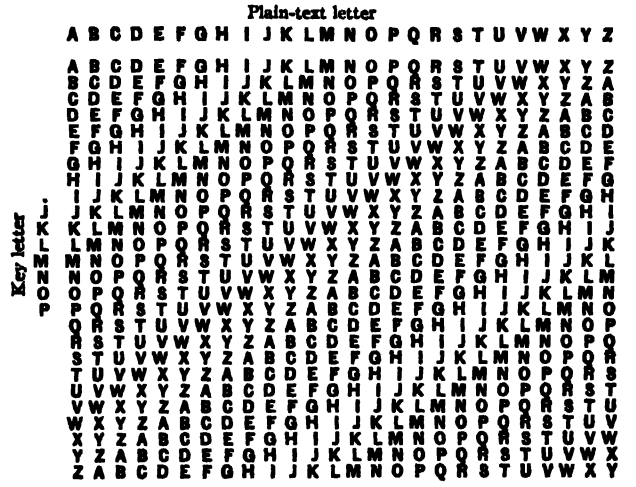

Fig. 4.—The simple Vigenère table. The cipher equivalent of a given plain-text letter enciphered by a given key letter is that letter which stands at the intersection of the vertical column headed by the former and the horizontal row begun by the latter. Thus, plain-text letter E enciphered by key letter M yields cipher letter Q, or, in brief notation, $E_p(M_k) = Q_c$; $E_p(X_k) = B_c$, etc.

Various modifications of the simple square table are encountered, these involving different types and arrangements of the sequences therein, but in every case where these sequences can be arranged so as to exhibit symmetry of position as regards the order in which the letters fall in the successive rows or columns, sliding or concentric primary sequences may be employed to produce the same results as the table and are often more convenient.

Polyalphabetic substitution systems may be classified as periodic or aperiodic, depending upon whether or not the cryptograms produced by them exhibit external phenomena of a cyclic nature. Periodicity is exhibited externally whenever the substitution process involves the use of keying elements which are used in a repetitive manner and which, in a single message, operate in conjunction with a fixed number of cipher alphabets, as would the example shown in fig. 5.

Polyalphabetic systems of the aperiodic type are of great diversity in construction. In these systems periodicity is either entirely lacking because of the nature of the method or it is suppressed by incorporating elements which serve as periodicity interrupters. In the well-known aperiodic system designated as the running-key or nonrepeating-key system, periodicity is avoided by employing for the key the running text of a book, identical copies of which are in possession of the correspondents. The starting point of the keying sequence is agreed upon in advance,

Key:	T R O Y T	R O Y T R	O Y T R O	Y T R O Y
Plain-text:	L E T T E	R N O T Y	E T R E C	E I V E D
Cipher:	E V H R X	I B M M P	S R K V Q	C B M S B

Fig. 5.—An example of multiple alphabet substitution. The alphabets of the simple Vigenère table (fig. 4) are used in conjunction with the keyword TROY, which is written above the plain text and repeated as many times as required. Each letter is then enciphered by the keyletter above it. Thus, for the first letter, $L_p(T_k) = E_c$; for the second letter, $E_p(R_k) = V_c$, etc. Usually all the plain-text letters governed by the first letter of the key are enciphered in succession, then those governed by the second, etc., this method reducing the possibility of error. In practice, the keyword, and therefore the period, is usually longer than that employed in this example, words and phrases of 15 to 20 or more letters being common. Much more important, however, is the fact that the alphabets employed in modern times are seldom those of the simple Vigenère table, but are mixed alphabets, the use of which makes the cryptograms more secure against solution.

or is indicated in one of many ways by means of elements called indicators, which designate the exact point where the sequence begins. Another type of nonrepeating-key system, often designated as the autokey system, is that in which, beginning with a preconcerted key letter, each cipher letter (or sometimes each plain-text letter) becomes the key letter for the encipherment of the next plain-text letter.

The various systems of substitution thus far mentioned are monographic in nature, involving single plain-text letters. In digraphic systems substitution is by pairs of letters and uses preagreed cipher squares or matrices in which the letters of the alphabet are disposed according to some key and the cipher equivalents of pairs of plain-text letters are found by following prearranged rules. One of the best-known systems of this sort is that called the Playfair cipher, named after Lyon, Baron Playfair, but invented by Sir Charles Wheatstone. It is illustrated in fig. 6.

Properly selected methods of transposition and substitution when combined into a single system result in producing cryptograms of great security, but because of the additional complexities of operation introduced by the combination, with the resultant increased possibilities of error, such systems are not often encountered in practice.

Cryptogram

4. GRQFE IXQYX LBBXL XEOAP HALI

Fig. 6.—The Playfair cipher; an example of digraphic substitution. An alphabet square of 25 letters (I serving also as J) based upon a keyword (in this case "Lexington") is drawn up, and substitution is performed with pairs of letters. Three cases as regards the position occupied in the square by the members of a pair are possible; they lie (1) in the same horizontal row, or (2) in the same vertical column, or (3) at the opposite ends of one of the diagonals of an imaginary rectangle. By studying the following examples under each case the method of finding equivalents will become apparent: Case (1) LI = EN, AB = BG, OB = AG; Case (2) ED = TP, EV = TE, PV = VE; Case (3) ER = IP, IM = LR, ST = PB. The text of the message to be enciphered, line 1 in the figure, is divided up into pairs, line 2. Double-letter pairs in the text are to be separated by an interposed letter such as X, as shown in the case of the word "following" in this example. Note also the addition of the letter "X" to the end of the message in order to make a pair of letters. The cipher equivalents are shown in line 3, the final cryptogram in five-letter groups, in line 4. Various arrangements of letters in the alphabet square are possible, and completely disarranged alphabets may be employed.

Code Systems.—Basically, a code system is merely a type of substitution system in which the textual units that undergo cryptographic treatment are of varying and unequal lengths. Generally they are entire words, but often they may be single letters, syllables, numbers or phrases of varying length and sometimes whole sentences. The cryptoprinciple underlying code systems is very old and has as its essential element a specially compiled list of words, phrases and sentences, each of which is accompanied by a code group which may be another word (real or artificial) or a group of letters or figures. Identical copies of specialized lists of the foregoing sort, called codebooks or codes, are held by the communicators. In encoding a message it is necessary merely to refer to the codebook and replace the words, phrases or sentences composing the message by the code groups assigned them, constructing the code message, step by step, in this manner and using the fewest code groups possible. As to their cryptographic construction or arrangement of contents, codes may be of the one-part or the two-part type, the principal difference between them being shown in fig. 7.

The condensing power of a code obviously depends upon the extent and the nature of its vocabulary. The security of a code system depends somewhat upon the distribution and construction of the codebook, but mostly upon whether it is used in conjunction with a good cipher system which is superimposed on the code text and the purpose of which is to afford secrecy, in the case of purchasable or publicly available codes, or additional secrecy, in

Fig. 7.—Extracts from typical one-part and two-part codes. In the one-part type the code groups and the vocabulary are arranged in parallel, alphabetic (or numerical) sequences, so that a single book serves for encoding as well as for decoding. In the two-part type the encoding book lists the elements of the vocabulary in alphabetic order but the code groups are in random order, so that a decoding book, in which the code groups appear in alphabetic (or numerical) order accompanied by their meanings, is essential. The degree of secrecy afforded by a code of the latter type is much greater than that afforded by one of the former type, all other things being equal.

the case of private or governmental codes. Code messages which undergo this second step are said to be superenciphered, reenciphered or, simply, reciphered. The principal purpose of code in commercial communications is to effect economy in their cost of electrical transmission, secrecy being usually of secondary importance (except in certain types of banking operations). Codes for general business communications are purchasable from their publishers and therefore in themselves provide no secrecy. Many business firms, however, use specially compiled private codes which, if carefully restricted in distribution, may be regarded as confidential or secret. In governmental and especially in diplomatic or military communications secrecy is generally of primary importance, economy is secondary.

Governmental codes which are intended to be secret are, of course, very carefully guarded in their production, distribution and usage and, as a general rule, messages in such codes are superenciphered.

Cryptoapparatus.—Cryptodevices and cryptomachines vary in complexity from simple, superimposed, concentrically or eccentrically rotating disks to large mechanical machines and electrically operated cryptoteleprinting apparatus. One of the best devices of the more simple, mechanical type is that known as the Bazeries cylinder (*see* fig. 8), named after the French cryptographer who is commonly credited with its invention in 1891. The principle upon which the device is based was, however, conceived

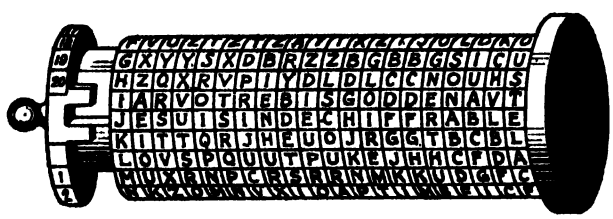

FIG. 8.—THE BAZERIES CYLINDER

The Bazeries cylinder consists of a set of 20 disks, each bearing on its periphery a differently mixed alphabet. The disks, which bear identifying numbers from 1 to 20, are assembled upon the shaft in an order that corresponds to a numerical key. To encipher the message, 20 letters are taken at a time, and the disks are revolved so as to align the 20 letters horizontally; the letters of any row can be taken for the cipher text. In deciphering, the cipher letters, taken 20 at a time, are aligned horizontally; the disks are then locked into position. By slowly revolving the whole cylinder and examining each row of letters, one and only one row will be found to yield intelligible text all the way across

many years before by Thomas Jefferson (*see* Jefferson's *Papers* in the Library of Congress, vol. 232, item 41,575).

Devices of the sort exemplified in fig. 8 soon proved to be inadequate for modern cryptocommunications, as regards not only speed, accuracy and facility in operation but also security of the end product. It was not long, therefore, before more automatic

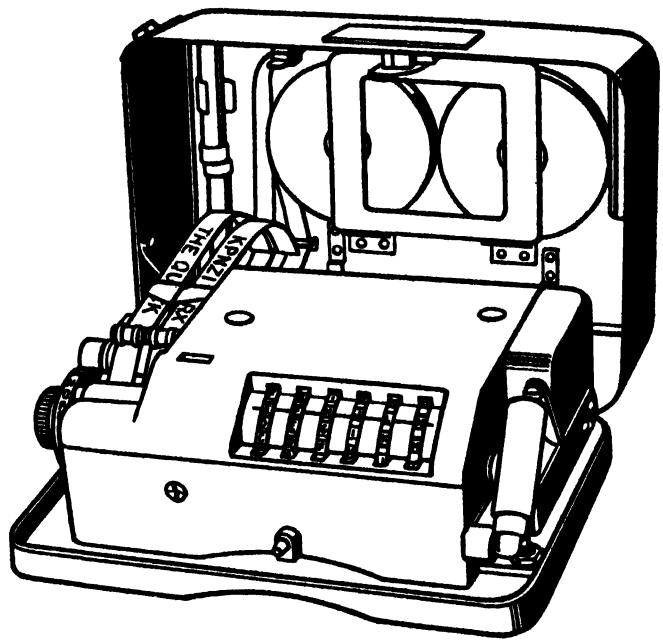

FIG. 9.—PORTABLE CRYPTODEVICE WHICH PRODUCES A PRINTED RECORD OF THE CIPHER TEXT AS WELL AS OF THE PLAIN TEXT. THE LETTERS TO BE ENCIPHERED OR DECIPHERED ARE SET BY TWIRLING THE INDICATING DISK SHOWN AT LEFT AND OPERATING THE LEVER AT THE RIGHT. THE SIX WHEELS CONTROL THE CRYPTOGRAPHY, IN CONJUNCTION WITH CERTAIN OTHER VARIABLE KEYING ELEMENTS INSIDE THE MACHINE

and more secure types of apparatus were invented and developed. In such apparatus rotatory components referred to as cipher rotors have come to be of primary importance. The rotors may be of a mechanical or an electrical type. Fig. 9 shows a machine which uses a series of mechanical rotors to produce an extremely long, continuously changing key for encipherment. Although the results of manipulating the machine are printed upon a paper tape, the absence of a typewriter keyboard makes operation of the machine slow and tedious. Fig. 10 shows a machine which uses a series of juxtaposed electrical rotors and stators to form a path for the passage of electric currents connecting the 26 keys of a keyboard to the 26 lamps of a light board upon which the results of manipulating the keys are indicated. Automatic angular displacements of the rotors serve to vary the path with each depression of any key of the keyboard. From a practical point of view such a machine is not satisfactory for offices engaging extensively in cryptocommunication since it lacks an automatic recording or

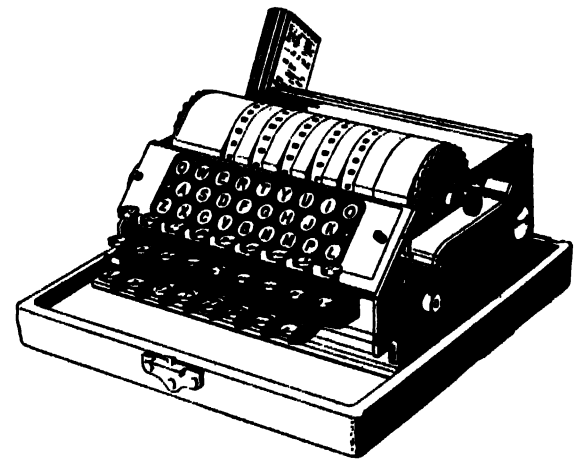

FIG. 10.—ELECTRICAL CIPHER MACHINE EMPLOYING A TYPEWRITER KEYBOARD

printing mechanism and the results of operating the keyboard have to be recorded by the operator by hand. Therefore, a machine combining both a keyboard and a printing mechanism had to come, sooner or later. Such a combination of components is shown in

fig. 11. Machines of this type, which are not necessarily associated with the electrical communication system but which merely produce an end product (a printed record) that can be given to a communication centre or telegraph office for transmission, are called off-line cryptomachines.

But even this stage in improvement in cryptocommunications

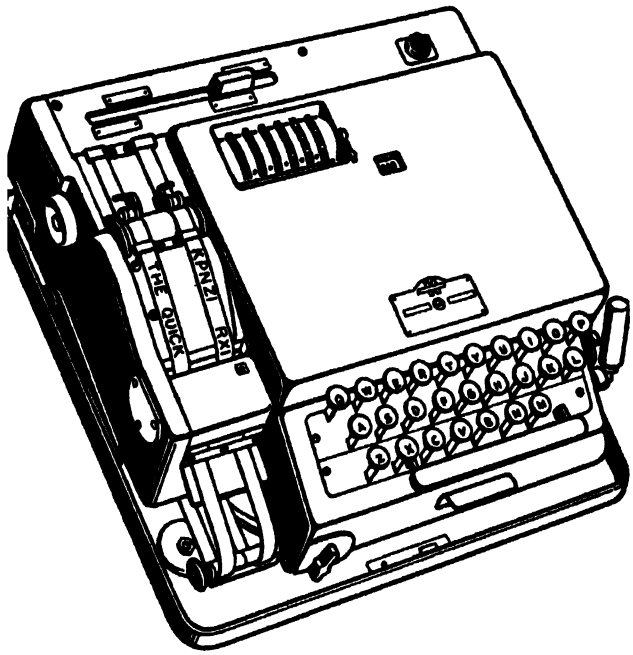

FIG. 11.—THE CRYPTODEVICE OF FIG. 9 EQUIPPED WITH A KEYBOARD AND DRIVEN BY AN ELECTRIC MOTOR. THE TWO MACHINES ARE CRYPTOGRAPHICALLY INTERCOMMUNICABLE. THE OPERATING LEVER AT RIGHT IS USED IN CASE OF POWER FAILURE

proved inadequate and communicators soon began to see need for on-line cryptomachines, *i.e.*, apparatus which combines in a single and instantaneous operation the following steps: (1) manipulation of a key of the keyboard at the transmitting station to correspond to a character of the plain-text message; (2) automatic encipherment of that character to form a cipher character; (3) electrical representation of that character by a signal or a permutation or combination of signals corresponding to the cipher character; (4) electrical transmission of the signal or signals; (5) their reception at the distant end; (6) their translation into a cipher character; (7) automatic decipherment of the character; and (8) printing the deciphered character—all this at the rate of at least 300 characters (=60 words) per minute. In fig. 12 is shown a prototype of such a machine. It is obvious, of course, that machines of this advanced type can be employed only where there is direct access to transmission and reception facilities.

As a result of extensive research and development after 1920, machines of the sorts here described have undergone considerable improvement, and further progress in written-cryptocommunications technology appears to lie in this direction.

Signal Intelligence.—The principal components of signal intelligence are: (1) communication intelligence, derived from the interception and analysis of signals which are involved in the exchange of messages or communications between persons and which are, therefore, of the type designated as communication signals; and (2) electronic intelligence, derived from the interception and analysis of electromagnetic radiations which are of a type other than those used in communications, such as radar, identification and recognition signals, navigational beacons, etc., and which are therefore designated as noncommunication signals. It should be noted, however, that it is often difficult to draw a line of demarcation between communication intelligence and electronic intelligence because these two fields deal with signals which merge into each other in the continuous spectrum generally referred to as that pertaining to communications electronics.

Communication Intelligence.—This phase of cryptology deals with the processes, methods or means employed in deriving information by intercepting and analyzing enemy communications. Its principal components are: (1) interception and forwarding of traffic (messages) to analysis centres; (2) traffic analysis, including radio direction or position finding and operator identification; and (3) cryptanalysis or solution (and translation, when necessary) of the texts of the messages. Only the last two components will be discussed.

Traffic Analysis.—Stated in general terms, traffic analysis involves studying the messages exchanged within a communications network for the purpose of penetrating the signal security camouflage superimposed thereon.

Such study permits reconstructing the networks from data such as volume, direction and routing of messages, frequencies, schedules and call signs used, etc. When the most important features of the networks have been thus ascertained, the analyst is not only able to ascertain the geographic locations and dispositions of military units (order of battle) and important movements of these units, but also to predict with varying degrees of reliability (based upon inferences) the area and extent of future military tactical or strategic operations.

Cryptanalysis.—The science of solving cryptograms by analysis is called cryptanalysis, to distinguish the indirect methods of reading cryptograms from the direct methods which, of course, require a knowledge of the basic method and specific key, in the case of ciphers, or possession of the codebook, in the case of codes. Apart from the more simple, classical types, nearly every scientifically constructed cryptographic system presents a unique case in cryptanalysis, the unravelling of which requires the exercise of unusual powers of observation, inductive and deductive reasoning, much concentration, perseverance and a vivid imagination; but all these qualities are of little avail without a special aptitude arising from extensive practical experience. It is worthwhile to note that the resistance which a specific cryptosystem will have against cryptanalysis is often vitally affected by the sophistication of the rules for its use and by the degree to which these rules are observed by cipher clerks. In respect to the latter, Francis Bacon's comment in his *Of the Advancement of Learning* (1605) is as true today as the day it was written: "But in regarde of the rawnesse and unskillfulnesse of the hands, through which they passe, the greatest Matters, are many times carryed in the weakest cyphars."

A preliminary requisite to the analysis of a cryptogram is a determination of the language in which its plain text is written, information which is either already at hand in the case of official communications or which, in the case of private ones, can usually be obtained from extraneous circumstances. Next comes a determination as to whether a cipher or a code system is involved;

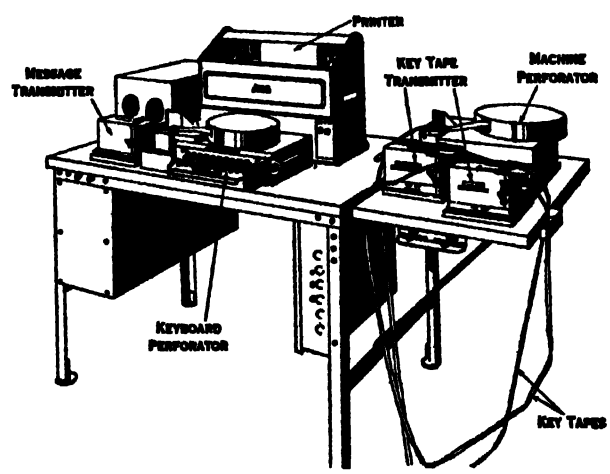

FIG. 12.—A PRINTING TELEGRAPH CIPHER MACHINE

this is based upon the fact that differences in their external appearance are usually sufficiently well marked to be detectable. If the cryptogram is in cipher, the next step is to determine whether transposition or substitution is involved. This determination is

made on the basis of the fact that in plain text the vowels and consonants are present in definite proportions. Since transposition involves only a rearrangement of the original letters, it follows that if a cryptogram contains vowels and consonants in the proportions normally found in plain text in the language in question, it is of the transposition class; if not, it is of the substitution class. The solution of transposition ciphers involves much experimentation with matrices of various types and dimensions, clues to which are afforded by the number of letters in the messages and extraneous circumstances. The assumption of the presence of probable words is often necessary. Special methods of solution based upon a study of messages of identical lengths, or with identical beginnings or endings, are often possible to apply when much traffic has been intercepted. Finally, the presence of letters which individually are of low frequency but which when present have a great affinity for each other and form pairs of moderate or high frequency, such as *qu* in Spanish or *ch* in German, afford clues leading to solution.

The basis upon which the solution of practically all substitution ciphers rests is the well-known fact that every written alphabetic language manifests a high degree of constancy in the relative frequencies with which its individual letters and combinations of letters are employed. For example, English telegraphic texts show the following relative frequencies in 1,000 letters, based upon an actual count of 100,000 letters appearing in a large but miscellaneous assortment of telegrams of a commercial and governmental nature, but all in plain language:

E	T	R	I	N	O	A	S	D	L	C	H	F
128	90	83	76	76	74	72	56	40	36	33	33	30
U	P	M	Y	G	W	V	B	X	K	Q	J	Z
30	27	25	21	18	14	13	11	5	3	3	2	1

These characteristic relative frequencies serve as a basis for identifying the plain-text values of the cipher letters, but only when the cipher has been reduced to its simplest terms. Thus, the problem of solving a monoalphabetic substitution cipher involves only one step, since the text is already in the simplest possible terms, and regardless of the kind of cipher alphabet employed practically every example of 25 or more characters representing the monoalphabetic encipherment of a "sensible" message in English can readily be solved by the well-known principles of frequency, made popular by Edgar Allan Poe's romantic tale *The Gold Bug*. However, the problem of solving a polyalphabetic substitution cipher involves three principal steps: (1) determining the number of cipher alphabets involved; (2) distributing the cipher letters into the respective individual frequency tables to which they belong; and (3) analyzing each of the latter on the basis of normal frequencies in plain text of the language involved. In the case of aperiodic ciphers, because of the absence of cyclic phenomena, these steps are often very difficult, especially when the volume of text is limited. Frequently the only recourse is to employ repetitions as a basis for superimposing separate messages so that, irrespective of the number of alphabets involved or their sequence, the letters pertaining to identical cipher alphabets fall into the same columns, and then the respective columns are treated as monoalphabetic frequency tables. The analysis of the frequency distributions of a polyalphabetic cipher is effected much more readily when the alphabets are interrelated than when they are independent.

The question as to whether an absolutely unsolvable cipher system can be devised is of more interest to laymen than to professional cryptographers. Edgar Allan Poe's dictum that "it may be roundly asserted that human ingenuity cannot concoct a cipher which human ingenuity cannot resolve" is misleading unless qualified by restricting its application to the great majority of the practical systems employed for a voluminous, regular correspondence. Isolated short cryptograms prepared by certain methods may resist solution indefinitely; and a letter-for-letter cipher system which employs, once and only once, a keying sequence composed of characters or elements in a random and entirely unpredictable sequence may be considered holocryptic, that is, messages in such a system cannot be read by indirect processes involving cryptanalysis, but only by direct processes involving possession of the key or keys, obtained either legitimately, by virtue of being among the intended communicators, or by stealth.

History.—It may as well be stated at the outset that as of the 1950s there did not exist in any language a detailed, authentic and publicly available history of cryptology. Moreover, because of the curtain of secrecy which is invariably placed around cryptologic work of an official character, accurate accounts of historically important events or of noteworthy inventions and improvements in cryptologic technology usually enter into the public domain only many years after the event or invention has occurred. Therefore, although it is difficult or impossible to ascertain with certainty much about the origin of any specific item or fact of cryptographic or cryptanalytic importance, the data should be traced back at least as far as the open or public records will permit. With this limitation in mind, this account will begin by noting that secret modes of signalling and communication have probably been in use from the earliest times, since the desire or need for secrecy in communication is certainly as old or nearly as old as the art of writing itself. However, mysteries such as the prophetic and apocalyptic writings of the orient and the sayings of the Sibylline oracles are generally not regarded by cryptologists as coming within their province; nor do they generally do anything more than merely refer to the various systems of stenography or shorthand used since the time of the Romans, including that known as Tironian notes, named after Tullius Tiro, Cicero's learned freedman and friend, who elaborated a system which was popular for almost 1,000 years. Although it is valid to assume that cryptography was used by all of the peoples of antiquity, the assumption has been confirmed in the case of Egyptian hieroglyphic writing by the outcome of studies which were begun by Jean François Champollion himself, were continued sporadically by other students for many years and culminated in 1932, disclosing that not one but three different sorts or degrees of cryptography were actually used by the ancient Egyptians. Cryptography was practised among the ancient Jews, whose Talmudic scholars dealt with it as a part or phase of their Kabbalah, which includes certain operations of a cryptographic nature. The ancient Greeks were users of the art, and at least one cryptographic device, called the scytale, is known to have been employed by the Lacedemonians for secret communications between military commanders in the field and their superiors at home. In the writings of Aeneas Tacticus (360–390 B.C.) is to be found the very earliest treatise on cryptography thus far discovered; in addition to treating of secret dispatches, they contain a description of a cipher disk, a detailed explanation of which cannot here be included. Numerous ancient Greek documents exist which are either partially or wholly in cipher; and one cipher alphabet found therein has been traced back to the 9th century A.D. Despite the fact that Roman cryptographic documents are rather rare it is well known that the Romans used ciphers, for there are numerous references to those which Caesar and Augustus employed. In fact, the name Caesar is often used in cryptologic literature to designate the type of cipher alphabet and cipher system known as the monoalphabetic cipher using standard alphabets. In the middle ages (*c.* 450–1450) cryptography was employed rather infrequently, for the most part in connection with the pseudo sciences of alchemy and astrology. The most widespread cryptographic system of that period corresponds to that used by the Roman emperor Augustus, in which a letter was merely replaced by the one following it in the normal alphabet (but *z* was replaced by *aa*). Most often, however, only certain letters were thus replaced, sometimes only the vowels.

The beginnings of modern cryptography can be traced back to Italy, the birthplace, as well, of modern diplomacy. Many cipher alphabets have come down to us which were used in the official messages of the papacy as well as in those of the early Italian republics. Ciphers were used in Venice as far back as in 1226; in Mantua and in Modena as early as 1305; and in Lucca, Florence, Siena, Pisa and Milan before 1450. It was also in Italy, beginning soon after 1500, that cryptologic operations first came to be organized on an effective basis. The invention of new cipher systems was promoted and reserves of cryptographic vocabularies

were prepared and kept in readiness for prompt issue as replacements for old or compromised ones. The earliest extant piece of work of a cryptographic nature is a small manual or compilation of the ciphers used about 1379 by Gabriel de Lavinde of Parma and preserved in the Vatican archives. In these ciphers all the letters were represented by arbitrary symbols and the vowels were treated no differently than the consonants in regard to the number of equivalents assigned them. However, some of these ciphers included nulls and others included brief lists of words and proper nouns, compilations first called nomenclators, then repertories and, later, small codes. By 1400 A.D. it had become apparent that each of the vowels should have more than a single cipher equivalent and there is a record of a cipher system involving a reversed standard alphabet with three different supplementary symbols as variants for each vowel. By the 15th century, according to Aloys Meister, Italian cryptography had been elaborated to the point where "three to six different symbols could be used to represent a single letter of the alphabet, the individual syllables—arranged alphabetically for this purpose, ba, be, bi, bo, bu, ca, ce, ci, etc.,— had specific cipher equivalents, and an ever-increasing number of complete words were incorporated into the nomenclators. Their abundance in content became so great that it was possible to fill a lengthy alphabetic index with the special equivalents for syllables and words . . ." The first complete cipher, *i.e.*, one containing arbitrary symbols for each of the letters and variants for the vowels, as well as nulls and a nomenclator, is exemplified by a Venetian cipher of 1411, cited by Luigi Pasini. In the first half of the 15th century, after some further expansion in content, nomenclators attained such a state of development and practical utility that they remained for centuries the prototype of the diplomatic repertories used by nearly all European governments, as well as by that of the young and rapidly growing republic in the western hemisphere, the United States. Before continuing with the account of the further development of cryptosystems of this sort it may be well to direct attention to the invention and development of another cryptosystem which, originating in the very simple devices of the ancients, culminated some time during the 16th century in the so-called *chiffre indéchiffrable* ("the indecipherable cipher") often referred to as the Vigenère cipher (fig. 4). It should be noted, however, that Vigenère's description of the cipher differs decidedly from the form usually ascribed to him and presents an essentially more difficult problem to the cryptanalyst, that Vigenère nowhere speaks of the cipher as the *chiffre indéchiffrable par excellence*, and that, except for an autokeying principle, Vigenère lays no claim to having originated the cipher.

Despite the much-advertised virtues and security of the Vigenère cipher, practical cryptographers and cryptanalysts tended to put their faith rather in the older nomenclators and repertories, and it is therefore necessary to turn once more to these cryptoaids and follow their progress.

The repertories used by France in the 16th century, under Louis XIII and Louis XIV, underwent important improvement with the introduction of an innovation which is now called the randomized or two-part arrangement of contents, illustrated in fig. 7. This improvement also soon found its way into the official cryptography of England and other countries. The repertories used by the papal court in the same century incorporated an additional new feature, that of making some or all of the cipher characters represent two or more different letters. After attaining this fairly advanced state of development, European cryptography went into a decline that reached its lowest level under Napoleon I; it is possible that one of the factors leading to the disaster which overtook him in Russia was the solution by the Russians of intercepted French ciphers. After the middle of the 19th century, stimulated perhaps by the spreading use of electromagnetic telegraphy, there came an expansion in the content of repertories, soon to be called codes. By the end of that century large codes containing 100,000 or more words and phrases were compiled not only for governmental but also for commercial communications. In such codes, of course, the length of the code equivalents had to be increased too, and code groups came to be composed, first, of groups of figures or of bona fide dictionary words, then of artificial words and, later, of five-letter groups constructed scientifically so as to obtain the maximum not only in economy in cost of transmission but also in efficiency in the correction of transmission errors. For another 75 years, beginning about 1860, the cryptoprinciples embodied in the early nomenclators but now expanded into large codes were the ones preferred for diplomatic and commercial cryptocommunications; literal or letter-for-letter ciphers were used only rarely for such communications. On the other hand, for military cryptocommunications, cipher systems of the latter type were preferred, except for high-level or strategic communications. In the U.S., during the War Between the States (1861–65), the Federal army employed small repertories in connection with word transposition, the so-called route cipher. The Confederate army used the Vigenère cipher—which the Federal army cryptanalysts are said to have solved every time a message in it was intercepted.

During the first two years of World War I cipher systems were used almost to the exclusion of code systems by all belligerents for protecting tactical communications in the field of operations, although code systems continued to be used for diplomatic and high-level strategic military cryptocommunications. By 1917, however, codes came to be used for the secret communications of the smaller and intermediate-size military formations. The extent of their vocabularies varied with the size of the unit, so that the code for communications between large units might contain 10,000 words and phrases, whereas that for communications between small units might contain only a few hundred or less. After about 1925 the direction of development and improvement in governmental cryptocommunications tended to explore and exploit the possibilities of automatic cipher machines, as indicated earlier in this article, and this took place in all types of secret communications: diplomatic, military, naval, air, etc. This change in direction of evolution and development of cryptosystems, code systems giving way to cipher systems in practical cryptocommunications where secrecy is the primary consideration, is only an obvious result, in the field of communications, of the increased tempo of mechanization in all fields since the beginning of the 20th century. Cipher systems, the units of which are generally single letters, lend themselves much more readily to mechanization than do code systems, the units of which are generally complete words and often long phrases or sentences, because the number and lengths of different permutations and combinations of electrical signals needed to represent the relatively small number of different basic units of a written alphabetic language (in English 26 letters) are very much smaller than the number and lengths of different permutations and combinations that would be required to represent the large number of different words in such a language, not to mention phrases and sentences.

This brief account of technological developments in cryptography has its counterpart in cryptanalysis, but if it is difficult to ascertain with certainty data concerning the origin of any specific cryptosystem, because of the veil of secrecy already mentioned, it is almost impossible to ascertain with certainty by whom, where or when a specific cryptanalytic principle or process was first conceived or employed. The secrecy veil in this area becomes an almost impenetrable curtain, so that it is certainly valid to assume that news of cryptanalytic success or of the invention of a new technique becomes public only many years after the events or, perhaps, never.

Under these circumstances, one hardly expects to find a historical account of the very first success in cryptanalysis, but the earliest brochure on record dealing with cryptanalytic theory is that of the Leone Battista Alberti, whose *Trattati in cifra*, written between 1467 and 1472, deals not only with cryptanalytic theories and processes but also with cryptography and statistical data. It is, therefore, the oldest treatise on cryptology in existence. The brief treatise of Sicco Simonetta, a cryptanalyst of the Sforzas at the court of Milan, which is dated July 4, 1474, and which is a strictly practical guide to cryptanalytic procedures, is the oldest treatise in the world purely devoted to cryptanalysis. Beginning

about 1506 and until 1539 another Italian professional cryptanalyst, Giovanni Soro, devoted his leisure hours to the preparation of a treatise which has never been found. As was the case with cryptography, so on the cryptanalytic side the activities in the various small Italian republics and the papacy came to be organized as serious enterprises. In order to protect these activities against indiscretions or "leakage," the principles of secrecy and security were firmly established and wilful violations were treated as capital offenses. The development of technical skill was rewarded, and instruction in cryptanalysis was often carried on from one generation to the next in the same family. But, as in the cryptographic field, so in the cryptanalytic field there have been periods of progression and retrogression in technology. However, after about 1930 cryptanalytic technology progressed rather notably. The mechanization which affected cryptography also affected cryptanalysis, and the invention and development or improvement of machines to aid in or speed up the tedious processes usually involved in the solution of complex cryptosystems exercised an important effect upon the standards by which cryptosecurity had to be measured.

The foregoing is a brief history of technological developments in cryptology. Nothing has yet been said about the usually very secret but quite important roles which poor cryptography or good cryptanalysis have played in international relations, both in peace and war, and in respect to both diplomatic and military affairs. As already stated, the historical accounts of these instances usually lag many years behind the events to which they relate. But in at least one case in modern history the revelation of the spectacular role played by cryptology in diplomacy and warfare took place not very long after the event. Hearings held in Washington, D.C., 1945–46, by the joint committee on the investigation of the Pearl Harbor attack, made it clear that shortly before and during World War II U.S. cryptanalysts had considerable success in solving Japanese codes and ciphers, success indeed to the extent that it was possible for the committee to state that all witnesses familiar with the intelligence produced "have testified that it contributed enormously to the defeat of the enemy, greatly shortened the war, and saved many thousands of lives." For other instances the reader must consult some of the books listed in the bibliography, but not many will be found that pertain to relatively recent history.

BIBLIOGRAPHY.—Although no comprehensive and authentic history of cryptology had been published by the 1950s, it is interesting to find that there does exist a comprehensive and scholarly bibliography of cryptologic literature covering practically all publicly available books and important papers on the subject: Joseph S. Galland, *An Historical and Analytical Bibliography of the Literature of Cryptology* (Evanston, Ill., 1945). Such a compilation is more helpful to specialists than to the general reader, therefore, a selection of items from the Galland bibliography may be useful. Also, after 1945 there were published a few items of importance which should be mentioned herein. Modern works worthy of special mention are as follows: André Lange and E.-A. Soudart, *Traité de cryptographie* (1925); Marcel Givierge, *Cours de cryptographie* (1925); Roger Baudouin, *Éléments de cryptographie* (1939); H. F. Gaines, *Elementary Cryptanalysis* (Boston, 1939; London, 1940); Luigi Sacco, *Manuale de crittografia*, 3rd ed. (1947); Charles Eyraud, *Precis de cryptographie moderne* (1953). (W. F. F.)

CODEX, the name given to the earliest forms of manuscript in book form (*i.e.*, the collection of written pages stitched together) which replaced the earlier roll of papyrus and the wax tablets (which when hinged or bound together formed the first codex or caudex); also the Latin form of the English word "code" (*q.v.*), meaning a body of law or regulations. For examples of famous codices, *see* the articles BIBLE; LIBRARIES; and PALAEOGRAPHY.

CODIAEUM, a small genus of Indo-Malayan shrubs belonging to the family Euphorbiaceae. One variety, *C. variegatum pictum,* a native of Polynesia, is cultivated in greenhouses and throughout the tropics under the name of "croton" for its magnificently variegated leaves.

CODINUS, GEORGE (GEORGIOS KODINOS), the reputed author of three extant works in Byzantine literature, two of which are anonymous in the manuscripts. It is supposed that Codinus lived toward the end of the 15th century. The works referred to are:

1. *Patria* (Τὰ ΠάτριαἘ Κωνσταντινουπόλεως). It is divided into five sections: (*a*) the foundation of Constantinople; (*b*) its topography; (*c*) its works of art and sights; (*d*) its buildings; (*e*) the construction of the church of St. Sophia. It was written in the reign of Basil II (976–1025), revised under Alexius I Comnenus (1081–1118) and perhaps copied by Codinus, whose name it bears in some (later) manuscripts. The chief sources are: the *Patria* of Hesychius Illustrius of Miletus, an anonymous (*c.* 750) brief chronological record (Παραστάσεις σύντομοι χρονικαί) and an anonymous account (διήγησις) of St. Sophia (ed. by T. Preger in *Scriptores originum Constantinopolitanarum,* fasc. i [1901], to be followed by the *Patria* of Codinus). (*See* also Procopius, *De Aedificiis,* and the poem of Paulus Silentiarius on the dedication of St. Sophia.)

2. *De Officiis,* a sketch of court and higher ecclesiastical dignities and ceremonies (*cf. De Cerimoniis* of Constantine Porphyrogenitus).

3. A chronological outline of events from the beginning of the world to the taking of Constantinople by the Turks (called Agarenes in the manuscript title). It is of little value.

BIBLIOGRAPHY.—Complete editions are (by I. Bekker) in the Bonn *Corpus scriptorum Hist. Byz.* (1839–43), where, however, some sections of the *Patria* are omitted, and in J. P. Migne, *Patrologia graeca,* clvii; *see* also C. Krumbacher, *Geschichte der byzantinischen Literatur* (1897).

CODLING MOTH (*Carpocapsa pomonella*), a small moth, the larva (caterpillar) of which is very destructive to apples and other fruit. Indigenous to Europe, it has spread, through the agency of commerce, wherever the apple is cultivated. The most effective methods of moth control are by sack-binding the tree trunks and by spraying with lead arsenate. (*See* ENTOMOLOGY: *Economic Entomology.*)

COD-LIVER OIL (*Oleum morrhuae*), the oil obtained from the liver of the common cod (*Gadus morrhua*) and other species of the family Gadidae. It is usually made by conducting steam into a tank of fresh livers until the mass boils vigorously. The liberated oil is promptly separated from the residue. Medicinal grades are subsequently destearinated by chilling to about 0° C. and filtering off the congealed "stearine." A technical grade known as cod oil, obtained by rotting the livers or liver residues, is used in tanning. The chief producing countries are England, Norway, Iceland and Canada; average annual world production during the years 1948–51, as reported to the United Nations, was 87,000,000 lb.

Chemically, cod-liver oil is a typical marine animal oil. It is a mixture of glycerides of many fatty acids, of which oleic acid, $C_{18}H_{34}O_2$, and gadoleic acid, $C_{20}H_{38}O_2$, are the most abundant. Some of the acids are highly unsaturated, which makes the oil subject to oxidation and causes the development of rancidity when exposed to air. The "stearine" fraction is not true stearin, but a mixture of fats of relatively high melting points. The oil contains about 1% of unsaponifiable matter, mainly cholesterol. Traces of iodine and other elements are present.

In the 19th century cod-liver oil was a folk-remedy for wasting diseases. During the period 1914–22 its medicinal value was clinically established and related to the presence of vitamin A and especially vitamin D. These vitamins comprise only a minute fraction of the oil, and the content is usually expressed in units; average oil contains 1,400 international units (I.U.) of A and 100 I.U. of D per gram. The vitamin potency varies considerably; it increases with the age of the fish and varies inversely with the fatness of the liver. It also varies with the species of fish, even within the cod family.

Cod-liver oil is a specific for rickets and other disorders of calcium metabolism resulting from a lack of vitamin D. It is a useful dietary adjunct in tuberculosis. It finds minor application in the treatment of night blindness and other manifestations of vitamin A deficiency. The greater part of the total production, in the form of undestearinated oil, is used in the feeding of poultry. The oil improves the production, hatchability, shell quality and vitamin content of eggs and makes possible the raising of chicks out of season and in the absence of sunlight. Some oil is used for raising pigs, dogs, fur-bearing animals and wild carnivorous animals in captivity. Herbivorous animals do not thrive on cod-liver oil, which to them is toxic.

During the period 1928–38 important new fish oils were developed as vitamin sources. Sardine (pilchard) body oil is slightly inferior to cod-liver oil but more plentiful. It is given to animals only, principally chickens, and usually after being fortified with synthetic vitamin D_3. Halibut, rockfish, dogfish and soup-fin shark liver oils are

outstanding sources of vitamin A. The liver oils of the percomorph fishes (tunas, mackerels, swordfishes and sea basses) often contain 100 times as much vitamin A and D as cod-liver oil. These oils, and oily solutions of vitamins A, D_2 and D_3, have surpassed cod-liver oil as vitamin sources in human medication.

See Fisheries Research Board of Canada, Bulletin 59, *Chemistry and Technology of Marine Animal Oils* (1941). (C. E. Bs.)

CODRINGTON, CHRISTOPHER (1668–1710), British soldier and colonial governor, whose father was captain general of the Leeward Islands, was born in Barbados, West Indies. Educated at Christ Church, Oxford, he was elected a fellow of All Souls, and served later with the British forces in Flanders, becoming a captain in the guards. In 1699 he was appointed captain general and commander in chief of the Leeward Islands. In 1703 he commanded the unsuccessful British expedition against Guadeloupe. After this he resigned his governorship and retired to a life of study on his Barbados estates. He died on April 7, 1710, bequeathing these estates to the Society for the Propagation of the Gospel for the foundation of a college in Barbados. This college, known as the Codrington college, was built in 1714–42. He also left a large sum to All Souls, with which the library named after him was established. He was buried in the college chapel.

CODRINGTON, SIR EDWARD (1770–1851), British admiral, belonged to a family long settled at Dodington in Gloucestershire. He entered the navy in 1783 and was promoted lieutenant in May 1793. Lord Howe selected him to be signal lieutenant of his flagship, the "Queen Charlotte," at the battle of the Glorious First of June, 1794. He was promoted commander after the action and captain in 1795, in which capacity he commanded the "Babet" frigate in Lord Bridport's action off Lorient. Between 1797 and 1805 he was unemployed and married in 1802 Jane Hall of Kingston, Jamaica. In 1805 he was appointed to the "Orion" (74 guns) and was selected by Nelson to command the rear squadron at the battle of Trafalgar. As this did not materialize, his ship fought in Nelson's column. In 1809 he was captain of the "Blake," flagship on the Walcheren expedition. Thereafter he served on the east coast of Spain and then, in the war of 1812–14, was active in North American waters during the operations against Washington, Baltimore and New Orleans. He became rear admiral in 1814, vice-admiral in 1821 and was appointed to the command of the Mediterranean fleet of 13 sail in 1827, flying his flag in the "Asia" (84 guns). In June 1827 he sailed to the Levant to command the allied fleet which at the battle of Navarino (*q.v.*) on Oct. 20 decided the independence of Greece by the destruction of the Ottoman fleet. During the period of his command the Aegean and the Adriatic were cleared of those pirates who had long been a menace to shipping in those parts. His victory at Navarino was the culminating event of his life, but it was received with mixed feelings in London, where it was officially described as "an untoward event" since it was held that Codrington had exceeded his instructions and that the diplomatic consequences were serious and unwelcome. The lord high admiral, the duke of Clarence, defended Codrington in the protracted correspondence which ensued, but he was recalled in June 1828, shortly before the Morea was finally evacuated by the Egyptians. On his return he published a justification of his conduct and in 1831 was employed again in the channel, becoming commander in chief at Portsmouth from 1839 to 1842. He died admiral of the White and G.C.B. on April 28, 1851, and is buried at St. Peter's, Eaton square, London. He left two sons who distinguished themselves, Sir William John (1804–84) as a soldier in the Crimea and Sir Henry John (1808–77) as admiral of the fleet.

See Lady Bourchier, *Memoir of the Life of Admiral Sir Edward Codrington*, 2 vol. (London, 1873); C. G. Pitcairn Jones (ed.), *Piracy in the Levant, 1827–28; selected from the papers of . . . Codrington*, Navy Records Society (London, 1934). (C. C. L.)

CODRUS, in Greek legend, the last king of Athens, son of Melanthus, of the Neleid family of Pylos, who came to Athens as a refugee. It was prophesied at the time of the Dorian invasion of the Peloponnesus (11th century B.C.?) that only the death of their king at the enemy's hands could ensure victory to the Athenians. Codrus therefore made his way disguised into the enemy's camp and provoked a quarrel, in which he was killed. The Dorians, on discovering this, retreated. The Athenians thought no one worthy to succeed Codrus and abolished the title of king, substituting that of archon (another version says that his son Medon was the last king). The royal families of Ionia as well as the Medontidae, the ruling family in Athens, claimed descent from Codrus. Codrus had a shrine in Athens, together with Neleus and Basile.

CODY, WILLIAM FREDERICK (1846–1917), famous U.S. frontiersman and showman, known as "Buffalo Bill," was born on a Scott county, Ia., farm on Feb. 26, 1846. At the age of 12 he shot his first Indian. Before the end of his teens and without the benefit of "book-learning," he had worked as horse wrangler and mounted messenger for a large western wagon freight firm, as a luckless prospector in the Pikes Peak gold rush and as a Pony Express rider. During the Civil War Cody served the Union as scout for the 9th Kansas cavalry in a campaign against Kiowa and Comanche Indians and was a U.S. army scout in Tennessee and Missouri military operations.

He married Louisa Frederici in 1866, but matrimony did not deter Cody one year later from hiring out as buffalo hunter for the firm of Goddard Brothers, then under contract to provide board for Kansas Pacific railroad construction crews. It was for his great success as a hunter that Cody won his lasting nickname "Buffalo Bill." Using a 50-calibre breech-loading Springfield rifle he killed (by his own count) 4,280 buffaloes during a period of 17 months.

During 1868–72, and again in 1876, Cody resumed duties as a U.S. army scout in prairie Indian campaigns. While serving Gen. George A. Custer in war against the Sioux, Cody killed and scalped Chief Yellow Hand in a duel. In this engagement Cody felled Yellow Hand with his rifle and within seconds, in the scout's own words, "I . . . had driven the keen-edged weapon to its hilt in his heart. Jerking his war-bonnet off, I scientifically scalped him in about five seconds."

Widely read dime novels featuring Cody's exploits made "Buffalo Bill" a household name. Cody was a superb showman. In 1883 he organized his Wild West exhibition, a large-scale, spectacular show which was successfully staged in the United States and Europe. A fortune made in showmanship was badly invested in various speculative ventures, among them ranching in Wyoming. On Jan. 10, 1917, Cody died and was buried in a tomb blasted from solid rock on Lookout mountain, 20 mi. from Denver, Colo.

Walsh, *The Making of Buffalo Bill: A Study in Heroics* (Indianapolis, 1928); Rupert Croft-Cooke and W. S. Meadmore, *Buffalo Bill: The Legend, the Man of Action, the Showman* (London, New York, 1952). (O. O. W.)

COEDUCATION. The term "coeducation" is given various interpretations, the most extreme being that girls and boys "shall be taught the same things, at the same time, in the same place, by the same faculty, with the same methods, and under the same regimen." Few would now go so far. The general attitude among those who favour coeducation is that the differences in physical make-up and mental disposition must be respected, but that underlying these differences are fundamental needs common to both sexes, and that these can be fully satisfied only if boys and girls share most lessons, much social life and some sports and pastimes.

Though coeducation has had advocates since antiquity—Plato favoured it—its practice on any large scale is quite modern; with rare exceptions, girls were not admitted to schools and universities before the 19th century. The principle is still far from being universally accepted. Where it is observed the reason is frequently expediency, not conviction; small numbers and limited resources permit only mixed schools. The chief—almost the only—area of controversy is the secondary stage of education; opponents of coeducation point out that during the years of adolescence girls and boys mature at different rates and have markedly different interests. Among the great religions, Roman Catholicism and Mohammedanism particularly frown upon coeducation; an encyclical of Pius XI in 1929 described it as "founded upon naturalism and the denial of original sin." Protestant Christianity on the whole favours it. With communism it is an article of faith, though one liable to question (*see* below).

England and Wales.—There has never been any official policy in England and Wales. The general feeling was well expressed in 1945

by the ministry of education, which wrote: "It is neither possible nor desirable to lay down a fixed doctrine. . . . In the fields of primary and further education co-education is to be preferred. It is in the secondary field that the rival advantages of separation make themselves most apparent." The ministry allowed, however, that there need be no "cause for regret" if necessity compelled the grouping of boys and girls together. In the public system of elementary education which grew up during the 19th century about half the schools were mixed, but this was almost exclusively for reasons of economy or numbers, and in many cases it was coinstruction rather than coeducation which was practised, the girls sitting on one side of the room and the boys on the other, and separating for play and other activities outside the classroom. Similarly, when the Education act of 1902 introduced a public system of secondary education, many mixed secondary schools were built, again largely for reasons of economy rather than principle. In Wales the proportion of mixed schools has always been much higher than in England, in part at least because of the sparsity of population outside the industrial areas.

The English so-called public schools have always been exclusively for boys. When during the second half of the 19th century secondary schools for girls began to be founded in considerable numbers, they too were almost invariably single-sex schools. Few changed from this organization. Most private schools, and especially private boarding schools, are for boys or girls only. There are a few notable exceptions; perhaps the best known is Bedales, at Petersfield, Hampshire. Founded as a boys' school in 1893 by J. H. Badley, it admitted girls in 1898 "because it could not do without them," and has not only acquired an international reputation but done much to advance the theory and practice of full coeducation.

Scotland.—The Scottish tradition is quite different from the English, partly, no doubt, because of the sparsity of the population and the isolation of the villages, but probably far more because of the egalitarian organization of society. Coeducation has been almost universally practised since at least the 17th century. The rule is broken here and there in the large cities, but rarely elsewhere, except in the handful of public schools on the English model. Private schools have never become acclimatized in Scotland and are few in number and inconsiderable in influence.

Other Commonwealth Countries.—In Australia conditions outside the capital cities usually compel mixed schools; in the cities large schools are frequently single-sex. In New Zealand almost all primary schools are mixed, but at the secondary stage there are many single-sex schools, especially among those privately owned. Similarly in South Africa the primary schools are all mixed, but a substantial number of the secondary schools are single-sex. In the French-speaking districts of Canada segregation normally begins at age 12–13; in the English-speaking districts coeducation is normal outside the large cities, but in the cities large schools are often single-sex. In India coeducation was not practicable on any large scale in the 1950s; although the number of girls and women in schools and colleges was doubled during the first seven years of independence, it was in 1954 only one-quarter that of boys and men, and the proportion in secondary and higher education was much smaller. In Pakistan an even smaller proportion of girls attended school, and in the Punjab province it was a legally recognized excuse for nonattendance that there was no school exclusively for girls in the district. A broad generalization about the other commonwealth countries is that primary schools are mixed, secondary schools much less frequently so.

Continental Europe.—In western Europe the Scandinavian countries are the extreme exponents of coeducation. Denmark accepted the principle in the 18th century, and all its primary and secondary schools are coeducational. In Norway coeducation was adopted by law in 1896; all its primary schools are coeducational and nearly all secondary, a few private schools being the only exceptions. Sweden adopted coeducation early in the 20th century, and except for a few secondary schools is wholly coeducational. Finland has a rather larger proportion of segregated secondary schools.

In the Netherlands coeducation was permitted in 1871 and by 1886 had become general except in Roman Catholic districts, which still uphold segregation at the secondary stage. In Belgium, on the other hand, two-thirds of the primary schools are single-sex and there are practically no mixed intermediate or secondary schools. In France local option decides whether the primary school shall be mixed or single-sex; the balance is about even. Segregation is almost universal at the secondary stage. In Spain the public system is coeducational, but private schools are usually single-sex. Portugal is exceptional in that segregation is usual at the primary stage, coeducation at the secondary. In Switzerland coeducation is the usual practice, though with some degree of segregation in senior classes in the towns. In Italy coeducation became the normal practice during the early years of the 20th century, but in many places it took the more limited form of coinstruction. In Greece all primary and about half the secondary schools are mixed. In Yugoslavia all schools are coeducational. In Ireland the primary schools are mixed, the secondary schools single-sex.

German elementary schools tend to be mixed, especially in rural areas, but coeducation has made little progress at the secondary stage. Until the closing decades of the 19th century it was practically impossible for a girl to get secondary education, and when girls' secondary schools were introduced they were of inferior status to boys.' Hitler increased this inferiority by excluding girls from *Gymnasium* courses. After World War II some *Länder* made coeducation their objective, but the tradition of segregation dies hard.

Russian policy has changed several times. Segregation was the rule, at least in the cities, in tsarist days. The soviet government early switched completely to coeducation, which for many years obtained throughout the U.S.S.R. In 1940, however, the Moscow city council asked permission to set up segregated secondary schools. The request was refused, but following prolonged discussion throughout the country the ministry of education in 1942 sanctioned a limited experiment in the city area. A year later the experiment was extended, and by 1947 segregation at the secondary stage was being practised in 400 large towns. Even so, only 13% of the school population was in single-sex schools, and there was reason to believe that segregation was introduced rather to meet wartime circumstances than on grounds of principle. In 1950 the controversy was reopened, and again the matter became one for prolonged public discussion. In the course of this it was stated that discipline had deteriorated in boys' schools, that in some girls' schools pupils had been discouraged from interest in science, agriculture, economics and industry, and that segregation was estranging boys and girls. In 1954 the council of ministers of the U.S.S.R. decreed the restoration of coeducation, which made for "uncomplicated and comradely relations between boys and girls." (H. C. D.)

United States.—Coeducation first became general in the United States (where the term itself originated) in the 19th century, although it had been adopted in a limited way in the 17th in elementary schools. The late 18th century saw its extension to a few secondary institutions, and in the 19th it invaded the collegiate field. Coeducation met varying degrees of opposition. Religious reform, political liberalism, revolution and industrialization were its allies; some segments of religion and politics were its foes. Western communities were more favourably disposed toward it than were eastern and southern. Public schools and Protestant institutions generally embraced coeducation, while Catholic schools did not.

Colonial practice varied according to sectarian and national factors and the age of the pupils. In New England young children of both sexes attended dame schools, but town schools, save in a few instances, excluded girls. In the latter half of the 18th century, girls were gradually admitted, but usually attended at hours and seasons when boys were not present. In New Netherland, Dutch parochial schools admitted girls and boys, "at least until they learned to read." In Pennsylvania, New Jersey and other Quaker settlements, girls and boys generally attended together. German communities favoured separation, but Christopher Dock had girls and boys in his Pennsylvania school. Political and economic change and educational reform broke with parochial education in the late 18th and early 19th centuries. The new public schools, which supplanted church institutions, were almost universally coeducational. At the end of the 19th century, only a few larger cities had separate schools.

Colonial Latin schools were for boys, and the earliest academies and seminaries embraced separation; but by the end of the 18th century certain schools ventured to bring both sexes together, in the same school, though not always on the basis of coinstruction. Noteworthy were Leicester academy (1784), Westford (1793), Bradford (1803) and Friends academy, New Bedford (1812), in New England, and Westtown Boarding school (1799) in Pennsylvania. High schools began, as did academies, on the basis of sex segregation, but coeducation was the dominant trend after the Civil War. By 1900 public high schools were 98% coeducational, as were 56.7% of private secondary schools. Coeducational private secondary schools fell, however, to 46.8% in 1920.

Collegiate education for women, developing out of the academy-seminary movement, followed the same course in regard to coeducation. The first colleges were separate, but coeducation soon swept the field. Oberlin (O.) college, coeducational in the preparatory department from the beginning (1833), admitted women to college classes in 1837. Numerous private institutions followed suit. Hillsdale (Mich.) college (1844) gave its first A.B. degree to a woman in 1852. Antioch college, Yellow Springs, O. (1852), led by Horace Mann, provided equal opportunities to men and women, with the same studies, classes and teachers. Eureka college (1855), Earlham college, Richmond, Ind. (1859), Albion (Mich.) college (1861) and Swarthmore (Pa.) college (1864) were coeducational from the beginning.

State universities followed the lead of private colleges in respect to coeducation, though not without opposition. The State University of Iowa, Iowa City, admitted women to the normal department (1856), sought to exclude them (1858) and granted a bachelor's degree to a woman in 1863. The University of Wisconsin, Madison (1850), proposed to admit women as well as men to the normal department, but none entered till 1860. Women entered college classes (1863), and all departments were declared open to them in 1866. Persistent efforts of the regents to separate the sexes were unsuccessful; by 1907 slightly more than half the students were women. The University of Michigan, Ann Arbor, was opened to women in 1870, and they entered all departments. Cornell university, Ithaca, N.Y. (1865), was designed to be coeducational, but despite Henry W. Sage's endowment (1872), women were still "definitely restricted" in the 1950s.

By 1870 coeducation was no longer a hazardous experiment. Numerous older colleges for men admitted women during the next decade. By 1880 colleges admitting women on a coeducational basis were 51.3%

of the total (excluding technical institutions and the special women's colleges); at the end of the century the proportion was 71.6%. Tulane, Columbia, Brown and Harvard avoided coeducation but opened affiliated women's colleges between 1887 and 1894.

Professional schools were loath to admit women, and professional associations opposed women's practice, but resistance crumbled in most of them in the latter half of the 19th century. The Geneva Medical School of Western New York (now Hobart college) admitted Elizabeth Blackwell to study medicine (1847), when she had been refused elsewhere, and gave her an M.D. degree two years later. Lemma Barkaloo entered the law school of Washington university, St. Louis, Mo., in 1869. The law school of the University of Pennsylvania, Philadelphia, admitted one woman in 1881. By the end of the century most law schools were willing to admit women on application, but Harvard, Yale and the University of Virginia, Charlottesville, still excluded them. Yale admitted women in 1918 and the University of Virginia in 1920. There were then only 1,171 women in 107 law schools, with 19,821 men. Women took 421 degrees in law in 1950, men 13,891. Theological schools continued to exclude women. At Oberlin, however, Antoinette Brown Blackwell finished the theological course in 1850. Hartford Theological seminary opened to women in 1889. In 1900 there were 181 women in 154 schools of theology, with a total of 8,009 students; two decades later, women approximated 14% of the student body, but few took degrees. Postgraduate schools, developing after 1876, were generally open to both sexes, but few women applied for entrance before the end of the century. The Johns Hopkins university, Baltimore, Md., a pioneer in graduate research, did not admit women till 1907. In 1900 women received 295 Master of Arts degrees and men received 1,106; 31 women and 312 men were granted the Ph.D. degree. All but two of the women Ph.D. recipients were in coeducational institutions.

Arguments for and against coeducation were exaggerated and mutually contradictory. Proponents of it in elementary and secondary schools saw it as natural and customary, the only just way for both boys and girls, harmonious, economical, convenient, beneficial, ameliorating in effect on manners and morals. Opponents thought segregation the "safer plan," especially in cities, better for both sexes, an aid to propriety and good morals; it had the sanction of custom, took account of differing abilities and facilitated corporal punishment of boys. Few efforts were made to study the effect of segregation scientifically. Englewood High school, Chicago, Ill., concluded, however, after a test involving about 1,000 boys and girls (1906–09), that for the sake of social environment the sexes should attend the same school, but be taught in separate classes, in order to adapt instruction better to the needs of both. As for coeducation in college, Oberlin's president reported, after long experience, that economy, convenience, stimulus to study, social cultivation, good order in school and community and preparation for later social life were the chief advantages of coeducation. As for the worst fears, studies had suffered no injury, health of women was good, morals and manners had improved and most graduates married. Time and custom added weight to this opinion, and the majority concurred; but a minority continued to consider coeducation the source of numerous social ills. (T. Wy.)

South America.—Each of the republics of South America has institutional variations peculiar to itself, in education as in virtually everything else. On the other hand, since all these countries have a great deal in common as to cultural heritage and social and economic problems, their social institutions often show close similarities. This is the case with coeducation. Two factors have militated against coeducation over most of Latin America: (1) industrialization, which intensifies the need for coeducation, is of late date even in the most developed countries; and (2) the Roman Catholic tradition is, speaking broadly, opposed to coeducation, particularly for adolescents. While in a few of the countries academic secondary education is coeducational, normal schools of the secondary education level are usually not coeducational. This is particularly true of urban normal schools. Most of the institutions of higher learning are coeducational, and the principal factor that keeps the enrolment of women at a low figure in universities is the limited demand for women in the professions. This lack of demand responds, of course, both to traditional customs and attitudes and to the limited number of positions for which women with university education can compete. (G. I. S.)

Orient.—For many centuries in China and Japan the belief prevailed that for a woman to assume her proper role in society—that of mother and wife—she required little in the way of formal education. Opportunity for formal education was practically nonexistent for the oriental woman until about the middle of the 19th century, when Christian missionaries established schools for girls.

In 1872 Japan established a nation-wide system of public education, and national laws provided for separate schools for the sexes. Several decades later, China started a system of public schools and patterned it after that of Japan. In both China and Japan coeducation was practised at first only in the primary grades. It was not until 1920 that government universities of these two countries began to admit women students. The number of women students entering the government universities was limited because in neither of these two countries were provisions made to allow girls to enroll in secondary schools of the college preparatory type. Shortly after World War II Japan took the final step toward a coeducational school system when it opened most of its public secondary schools to boys and girls alike. By the midpoint of the 20th century coeducation, as a principle of public education, had taken a firm foothold in the orient.

Increased contact with western cultures and the consequent spread of liberal western social and political philosophies among the general populace was the major factor in the adoption of the principle of coeducation in China and Japan. Another factor contributing to the adoption of this principle was the economic difficulty of maintaining a system of schools for each of the sexes. (J. I. D.)

COEFFICIENT. This term was introduced into algebra by François Vieta at the close of the 16th century to denote either of the two rational factors of a monomial. Thus in the expression ab, either a or b is the coefficient of the other. In the case of a product of a constant by a variable, it is usual to call the constant factor the coefficient. Thus the numbers 2, -1, 0, a are the coefficients of the polynomial $2x^3-x^2+a$.

The integer $\binom{n}{r}=\frac{n!}{r!(n-r)!}$ is the coefficient of the term $x^r y^{n-r}$ in the expansion of $(x+y)^n$ by the binomial theorem. Such integers are called binomial coefficients.

If $z=f(x,y)$, then $dz=\frac{\partial f}{\partial x}dx+\frac{\partial f}{\partial y}dy$ so that the partial derivatives $\partial f/\partial x$ and $\partial f/\partial y$ are often called differential coefficients.

In physics and mechanics, the term "coefficient" is applied to a number of constants which have to be determined experimentally. Thus if F is the force due to friction between two surfaces, and if N is the normal pressure between the surfaces, then $F=\mu N$ where μ is a constant depending on the condition and nature of the surfaces in contact, called the coefficient of friction.

A body normally expands when heated, and the change in length of a bar of unit length per degree change in temperature is a constant, called the coefficient of linear expansion of the substance.

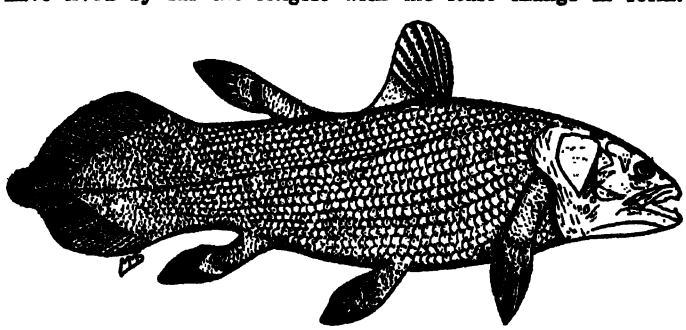
The coefficient of pressure of a gas is the ratio of the change in pressure per degree to the pressure at the ice point, the volume remaining constant.

In the division of one polynomial by another, the method of detached coefficients may be used. When the divisor is of the form $x-c$, the method is particularly simple, and is known as synthetic division. Let it be required to divide $3x^4-8x^3-2x+5$ by $x-3$. The coefficients of the dividend are written down in order, 0's being supplied if not all powers of x are present. The first coefficient is brought down unchanged. This is multiplied by 3 and added to the next coefficient. The sum 1 is multiplied by 3 and added to the next coefficient, etc. The partial quotient is

3	−8	0	−2	5	
	9	3	9	21	
3	1	3	7	26	

$3x^3+x^2+3x+7$ with the remainder 26. (*See* Algebra; Polynomial.) (C. C. M.)

COEHOORN, MENNO, Baron van (1641–1704), Dutch soldier and military engineer, of Swedish extraction, was born at Leeuwarden in Friesland and became a captain in the Dutch army. In 1673 he took part in the defense of Maastricht and in the siege of Grave, where the small mortars (called coehorns) he invented troubled the French garrison. He was made a colonel for his conduct at the battle of Seneff (1674), and was also at the battles of Cassel (1677) and St. Denis (1678). He was an innovator in fortification, and his first published work, *Versterckinge de Vijfhoeks met alle syne Buytenwerken* (Leeuwarden, 1682) caused a controversy with Louys Paan (Leeuwarden, 1682, 1683); Coehoorn was entrusted with the reconstruction of several fortresses in the Netherlands, and became the



worthy rival of his great contemporary Sébastien de Vauban. In his chief work, *Nieuwe Vestingbouw op en natte of lage horizont,* etc. (Leeuwarden, 1685), he laid down three "systems," the feature of which was the multiplicity and great saliency of the works, eminently suited for flat sites such as those of the Low Countries. He borrowed many details from his Dutch predecessor Freytag, or from Albrecht Dürer, and Speckle, and studied the individual case, not theoretical perfection; *e.g.,* at Groningen. From 1688 to 1697 Coehoorn was a brigadier. At Fleurus he distinguished himself. In 1692 he lost Namur, a fortress of his own, to Vauban, but retook it in 1695. Coehoorn became lieutenant general and inspector-general of the Netherlands fortresses, and the High German peoples as well as the Dutch honoured him. He commanded a corps in Marlborough's army from 1701 to 1703, and in the constant siege warfare his skill was of the highest value. The swift reduction of Bonn and the siege of Huy in 1703 were his crowning successes. He died of apoplexy at Wijkel on March 17, 1704.

His first system was applied to Nijmegen, Breda, Bergen-op-Zoom and Mannheim, his second to Belgrade and Temesvar among other places.

His son, Gosewijn Theodor van Coehoorn, wrote his life (re-edited by Syperstein) (Leeuwarden, 1860); his *Nieuwe Vestingbouw* was translated into English by T. Savery (1705).

COELACANTH. Coelacanths are fish which originated about 350,000,000 years ago and spread over much of the world, leaving numerous fossil remains which apparently ceased 60,000,000 years ago. It was therefore startling when the first living coelacanth (*Latimeria chalumnae*) was trawled in 40 fathoms near East London, U. of S.Af., in 1938. The second was caught by a native on a line in about 40 fathoms near the Comoro Islands in Dec. 1952. This, *Malania anjouanae,* a male, lacked a first dorsal and extra tail but was probably mutilated in early life. So little was known about coelacanths that it was believed further specimens might show the two to be male and female of the same species. The sex of *Latimeria* was unknown as the soft parts were lost.

Coelacanths are grouped in four families, three extinct and one existing, Latimeriidae. These fall in the superorder Crossopterygii (fringe-finned), the early forms of whose two related orders, Coelacanthini and Rhipidistia, lived in swamps and probably crawled out of the water. Rhipidistian descendants colonized the land, but coelacanths remained aquatic, some probably always marine, leaving no fossil remains. Of all creatures coelacanths have lived by far the longest with the least change in form.

MARGARET M. SMITH

COELACANTH LATIMERIA, A MEMBER OF THE ONLY EXISTING FAMILY OF COELACANTHS, THE OTHER THREE BEING EXTINCT

Close links with the remote past, they may shed light on the earliest life.

Coelacanths have characteristic limblike fins, probably still used today for crawling about in the sea. The tail is large, symmetrical and in most fossil and one recent form there is a small extra tail behind. The skeleton is mostly cartilage, but part of the skull and the basal plates of the fins in the body are bony. The powerful mouth differs from that of most fishes, lacking the "maxillary" bones in the upper jaw. The gill arches are bony, with strong teeth above. Even early coelacanths had scales overlapping like those of modern fishes, with a lateral line.

Coelacanths are robust and powerful flesh eaters, almost certainly dwellers among reefs, where they pounce on prey. The intestines are short and include a spiral valve. Inside *Malania* were the eyeballs of a fish of at least 15 lb. weight.

Modern coelacanths are bigger than most fossil forms. *Latimeria* was 60 in. long and weighed 127 lb., *Malania* 54 in. and 87 lb. In 1953 and 1954 five more coelacanths were captured and preserved at the Comoros, establishing this as their home.

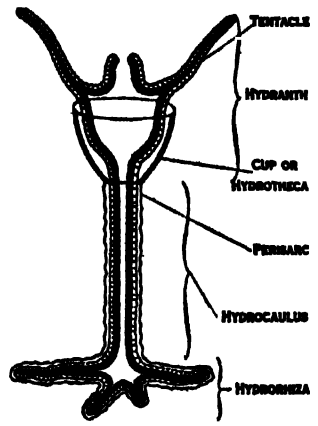
(J. L. B. S.)

COELENTERATA. The term "Coelenterata" is applied to a large group or phylum of animals of a lowly grade of organization. Only three types of animals possess a simpler structure than the Coelenterata: the sponges, the Mesozoa and Protozoa. Protozoa are organisms whose body usually consists entirely of a single cell, generally of microscopic size. In certain instances a number of these cells become banded together to form a colony, but in such a case they are not arranged so as to constitute tissues, and are individually autonomous and self-supporting. The sponges consist of a multitude of cells of different kinds which are massed together and many of which are segregated into definite sheets or tissues, each sheet performing a function or functions of its own. A sponge develops from a definite embryo which is the outcome of the cleavage of a fertilized egg, but apart from this it is very unlike the animals of the higher groups in that it constitutes in its adult condition a fixed, plantlike object often of somewhat indefinite shape. The sponges probably represent a series of products of evolution which diverged from protozoan ancestors in a direction distinct from that pursued by any other animals and which led to nothing beyond the sponges themselves. The Coelenterata, however, from beginnings similar to those of the sponges, achieved an altogether higher grade of organization, producing not only tissues but also a much more definite form and individuality than the sponges, involving the differentiation of nervous and muscular systems and consequently efficient co-ordination of parts and considerable powers of movement and locomotion. In the sponges primitive muscular tissue exists locally, but there is no nervous system.

Structure of a Coelenterate.—The body of a coelenterate resembles in architectural principle that stage which may be recognized in the early development of so many animals above the degree of sponges and which is known as a gastrula (fig. 5). A gastrula consists of a small sac, with a single opening at one end (the blastopore). The walls of the sac possess two layers of cells, one passing into the other at the margin of the blastopore. The inner layer is known as endoderm, the outer as ectoderm. No coelenterate, however complex may be its structure, passes beyond the fundamental plan thus outlined; though its size may be great and its parts elaborate, it remains an animal possessing one principal internal cavity only, the coelenteron, which opens to the exterior by a single main aperture, the mouth. In a typical higher animal the body contains two principal cavities, the food canal and another main cavity situated between the wall of the food canal and the outer integuments of the body. In such a form the food canal opens to the exterior by a second aperture (the anus) through which the undigested material is voided; the Coelenterata possess no such opening, and waste substances are ejected through the mouth. There is, in fact, no existing coelenterate in which the adult animal is quite so simple as a gastrula; but there do exist creatures in which the main differences are that the cells of the ectoderm exhibit a differentiation into more than one kind, and that there lies between ectoderm and endoderm a thin sheet of noncellular material, the mesogloea, which supports the other layers. An example of such a grade of structure may be found in *Protohydra.*

The majority of Coelenterata, however, develop a complexity far exceeding this. The actual form of the body varies almost infinitely, but usually a prominent feature of the organization is the presence of a number of tentacles placed in a definite manner around the mouth. These tentacles may be solid structures, containing a core of endoderm and a covering of ectoderm, or they may be hollow, the wall in such case including both cell layers. The symmetry of the body is usually characterized by the fact that the various parts are arranged about the radii of a circle with

the mouth as its centre, and that the same structures are repeated in a regular manner in different sectors. In other words, the animal is radially symmetrical and can be divided by suitable radial cuts into a varying number of parts each of which is exactly equivalent to the others. This symmetry is not invariably present, but is extremely prevalent, although in one section of Coelenterata (the Anthozoa) it is accompanied by an underlying bilateral symmetry which mars its perfection. The middle layer or mesogloea varies greatly in bulk in different cases, being sometimes extremely tenuous and small in amount, sometimes very extensive and forming the greater part of the mass of the organism.



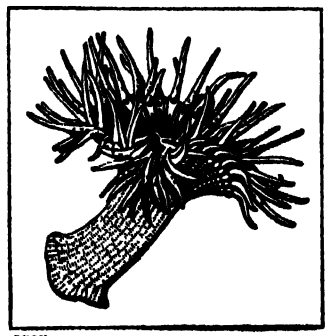


FIG. 1.—DIAGRAM OF A TYPICAL HYDROID POLYP

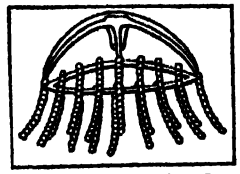
Polyp and Medusa.—The Coelenterata exhibit two main types of shape, both founded upon the gastrula plan.

1. *The Polyp.* The name *polyp* (figs. 1 and 2) is derived from the French *poulpe*, a term applied to an octopus. There is no actual relationship whatever between a Coelenterate polyp and an octopus, the comparison having been suggested by the fact that both of them possess mobile tentacles. A good example of a polyp is a sea anemone, the essentials of its structure being a hollow cylindrical body closed in below by an adherent disc-like base, above by another disc (the *peristome*) bearing the mouth in its centre and a circlet of tentacles round its outer part. Details of the structure of different kinds of polyps are given in the articles HYDROZOA, ANTHOZOA and SCYPHOZOA.



FROM COURTESY OF THE RAY SOCIETY

FIG. 2.—A SEA ANEMONE, ILLUSTRATING THE APPEARANCE OF A TYPICAL POLYP

2. *The Medusa.* Those Coelenterates popularly known as "jelly-fish" are scientifically christened medusae, the name referring to the resemblance borne by the long mobile tentacles of some of these animals to the writhing, snaky tresses of the Gorgon Medusa. The body of a medusa (fig. 3) is shaped like an umbrella, and hanging down inside it from the point at which the handle of the umbrella would be attached, is a structure known as the *manubrium*, at the end of which is the mouth. In this case the tentacles form a circlet round the margin of the umbrella. *See* HYDROZOA and SCYPHOZOA.

Alternation of Generations.—One of the most interesting features connected with the Coelenterata is the fact that a single animal may for part of its life be a polyp and for part a medusa; or from a polyp, buds may be formed which develop into medusae. In cases such as the latter it is the polyp which is developed from an egg, and this polyp itself produces no sex-organs; it is able however to give origin to vegetative buds which develop into medusae, and these in their turn bring forth sex-cells which after fertilization initiate further polyps. In this way there is regular alternation between polyp and medusa and the phenomenon is termed *metagenesis* or alternation of generations. By some authors the polyp is viewed not as a "generation" but as a persistent larval stage; the medusa is then regarded as the adult.

FROM PARKER & HASWELL, "TEXT BOOK OF ZOOLOGY" (MACMILLAN & CO. LTD.)

FIG. 3.—THE MEDUSA OF OBELIA

Polymorphism and the Formation of Colonies.—Another marked characteristic of the Coelenterata is their tendency to form colonies of individuals united to each other by a common stem, plate or mass of intermediate tissue. The colonies so formed are generally attached permanently to foreign surfaces, but in some cases they form strings or aggregations of individuals which float or are propelled through the sea. Coelenterate colonies are frequently characterized moreover by the production in one and the same colony of different kinds of individuals, among which the various functions are distributed. There may co-exist in a single colony not only polyps as well as medusae (fig. 4), but more than one kind of each of these types of individuals. There may be sexual medusae and medusae transformed into locomotory organs; polyps whose main function is digestion and others which catch and paralyse prey; and so forth. The phenomenon thus outlined is known as *polymorphism* and metagenesis is a form of it; it is one of the most interesting manifestations of the diversity of animal life, and is considered in more detail at the end of the article HYDROZOA.

OGIE" (WALTER DE GRUYTER & CO.)

FIG. 4.—PART OF A COLONY OF CORYNE, MUCH ENLARGED

Development.—The Coelenterata pass during the course of their life-history through a series of stages very unlike the adult animal. A simple instance of these stages is provided by the embryology of the common sea anemone, *Metridium senile* (fig. 5). In this species the eggs are shed into the sea by the parent and are there fertilized. After fertilization the egg divides into halves and each of these once more into two. The four cells (or *blastomeres*) so formed are equal or sub-equal in size. This process of subdivision is continued until a considerable number of small cells has been formed, and these are so arranged as to constitute a hollow sphere containing fluid. The sphere is known as a *blastula* and the cavity as a *blastocoele*. The blastula continues to develop in such a way that one side of the sphere first flattens and then becomes concave, being finally completely invaginated into the other half. This process practically obliterates the blastocoele, and forms in its stead a second internal cavity, the *archenteron*, which communicates with the exterior by means of a small opening, the *blastopore*. There has thus been produced a typical gastrula such as has been previously described; its archenteron becomes directly transformed into the coelenteron of the

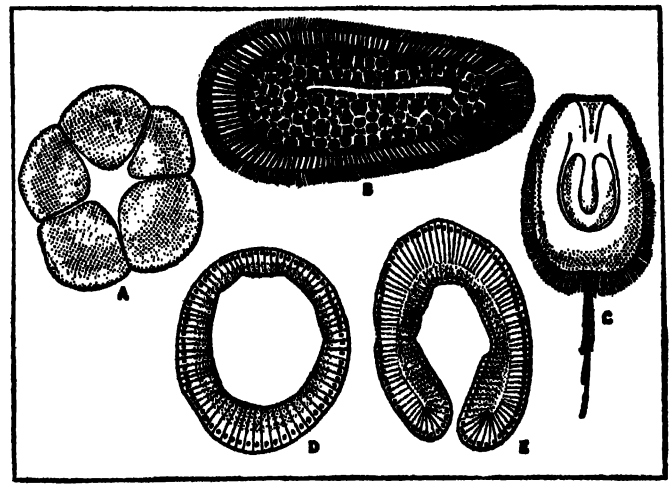


FIG. 5.—STAGES IN DEVELOPMENT OF CERTAIN COELENTERATES
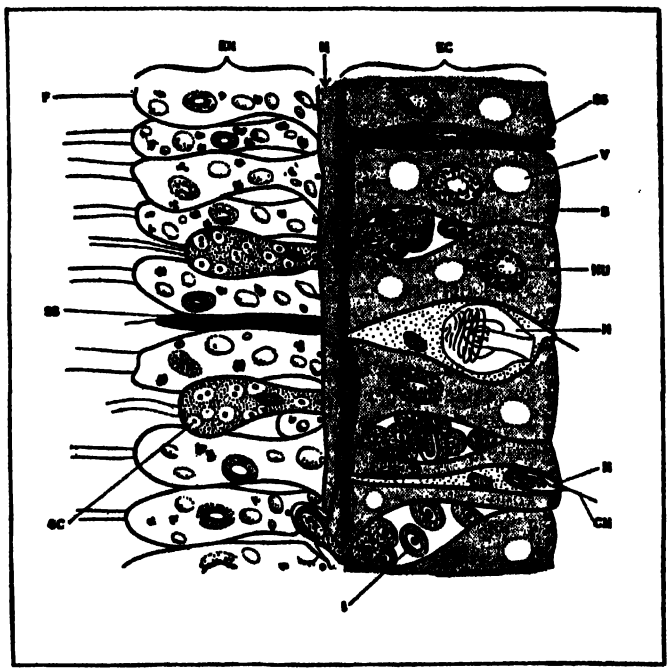
A. Section through an early stage in cleavage of the egg of a sea anemone (*Metridium*). D. and E. later stages—blastula and gastrula. B. A planula belonging to a hydrozoan. C. Late larva of a sea anemone

adult, and the blastopore becomes the adult mouth. During its early stages the animal moves through the water by the aid of cilia which appear on its outer surface during the blastula stage, but before it begins to assume the adult shape it tends to remain at the bottom, moving horizontally and resting from time to time, and often becoming temporarily attached to the bottom mouth downwards, during which time it may execute slow creeping movements. From this larva the adult anemone-polyp is achieved by degrees. At a given time the larva settles down and attaches itself to a foreign surface; its proportions change, it acquires tentacles, and becomes a small polyp.



The embryology of the Coelenterata varies considerably from one species to another, but generally speaking it is characterized by the presence of a gastrula-stage or of some equivalent. Frequently no actual gastrula exists but instead a corresponding stage known as a *planula* is produced, in which there is no blastopore, the embryo consisting either of a hollow two-layered organism or of a central mass of endoderm-cells covered externally by a layer of ectoderm (fig. 5). Planulae and gastrulae may be free-swimming organisms moving by means of cilia, or may be contained within the coelenteron of the parent or within a protective enclosure so that they have no actual free existence, and are born as young polyps.

Motion.—The movements of which a Coelenterate is capable depend upon its shape, organization and mode of life. A jellyfish is an active free-swimming creature which progresses through the water as a result of rhythmic or spasmodic contractions of its bell-like body brought about by the action of muscles. Different kinds of jellyfish are active in varying degrees; some are much stronger swimmers than others, some are decidedly sluggish, whilst a few are creepers. Movement in polyps varies according to whether they possess a skeleton or not; in those provided with such a structure movement is naturally limited to those actions which the tentacles or other parts of the polyp can perform unrestricted by the hard parts. If a polyp is free from skeleton, it can move in a variety of ways; rarely, it swims actively by concerted lashing movements of the tentacles; sometimes it will creep on these organs; or it may attach itself by the base, bend over and attach the tentacles, then loosen the base, move its body and re-attach the base elsewhere. On the other hand it may simply loosen its hold and allow the motion of the water to carry it elsewhere, and in such case may inflate itself with water in order to become more buoyant; or it may creep upon its base, a method characteristic of many of the large polyps of the sea anemones.

The movements exhibited, apart from those connected with actual locomotion, consist of contractions and expansions of the tentacles and body, movements of the mouth, and so forth, connected with capture and swallowing of food, with retraction for the purpose of sheltering from adverse conditions, and with similar matters. Tentacles are usually highly contractile, and in their most concentrated condition are very much smaller than when expanded. The whole body may be relatively rigid and not, as a whole, very contractile, in forms possessing a high development of the mesogloea; but in many cases it is as contractile as the tentacles and may be reduced at need to a bulk very much smaller than its size when expanded; *e.g.*, to an eighth of its maximum bulk.

Muscles.—Although the general substance of a Coelenterate is contractile, the definite movements which it performs are the result of muscular or ciliary action. The muscular system in its simplest condition consists of a single layer or sheet of muscle-fibres, lying on the inner or outer surface of the mesogloea. The muscle-sheets of Coelenterates are normally only one fibre thick, and each fibre lies directly upon a supporting surface of mesogloea. Consequently if strong localized muscles (as distinct from diffuse sheets) are required, these are generally attained by the simple expedient of pleating the surface of the mesogloea into ridges, on the surface of which lie the fibres, still in a single layer. In certain cases muscle becomes embedded in the mesogloea. The individual fibres are not in the simpler instances independent structures, but belong to and form part of epithelial cells of the ectoderm or endoderm. Thus the combination of each cell with its "muscle tail" (or tails) constitutes a musculo-epithelial cell, a structure characteristic of Coelenterata but rare among higher animals (fig. 8). In more specialized cases the muscle-fibres of the ectoderm become separate structures, the epithelial cells which produced them being of insignificant proportions.

The Finer Structure of the Tissues.—The structure of the layers of the body must now receive short notice (fig. 6). The

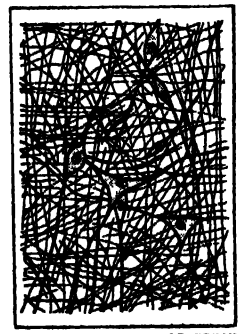
mesogloea is a sheet of very variable structure; sometimes it is gelatinous in texture, sometimes almost cartilaginous, or again it may be very watery and unsubstantial. It contains within its substance cells which have wandered there from the other layers, and the functions of which are not fully understood. Some of them at least are amoeboid cells which carry or transmit nutriment from the endoderm (the digestive layer) to other parts of the body. Others probably add to the mesogloeal substance by secretion, whilst it is possible that some of them constitute part of a mesogloeal nervous system. At its highest development the mesogloea possesses fibres as well as cells, but these are not at all of the same nature as the muscular fibres. The cell-layers are best considered separately, and the following details apply to a sea anemone, which will serve as a suitable example. The ectoderm is an epithelium consisting of elongated supporting cells which are ciliated in some parts of the body, and among these occur large numbers of cells of other kinds. There are glandular cells which secrete mucus, etc., sensory cells which constitute the peripheral receptive elements of the nervous system, cnidoblasts which secrete curious explosive capsules about which more will be related shortly, and undifferentiated interstitial cells which may give rise to other kinds at need. In the deeper parts of the epithelium lie nerve cells (the nervous system is further described below) and on the surface of the mesogloea, in given parts of the body, are the muscle fibres, which are here independent of the supporting cells. The endoderm resembles the ectoderm in general constitution, but its supporting cells, instead of being ciliated, bear each a single large cilium or flagellum, and each possesses a basal muscle fibre, and so constitutes an epithelio-muscular cell. Many of them are digestive in function. Gland-cells are to be found in the endoderm, as also are sensory, nervous and interstitial cells; cnidoblasts are most characteristic of the ectoderm, but also occur freely in the endoderm where necessary.

The germ cells of the Coelenterata, those cells which will in due course form eggs or spermatozoa, are formed sometimes from

interstitial cells, sometimes from differentiated epithelial cells. They may originate in either ectoderm or endoderm, but are not necessarily first formed in the region in which they will ripen.

General Functions.—The Coelenterata possess no special organs for respiration or excretion, and possess neither blood nor blood-vessels. Respiration and excretion are performed by the general surfaces of the body, but sometimes the chief excretory areas are localized. Circulation in the true sense does not exist, although currents are produced in the fluid contained in the coelenteron by means of the endodermal flagella. The distribution of substances through the tissues takes place partly through the agency of amoeboid cells and partly by diffusion. Feeding and digestion must be more closely considered.

Capture of Food.—The Coelenterata are apparently all carnivorous, and capture food by two principal methods. The commonest way is to seize the prey with one or more of the tentacles, to convey it to the mouth and swallow it. This is made possible by the fact that the tentacles possess stinging and adhesive powers of a high order. A tentacle will adhere to and will paralyze or kill any organism which is desired for food, provided that the prey in question is not too large or too tough to be penetrated by the poisonous threads shot out by the tentacle. These threads are shot forth in countless numbers from the tentacle-surface, each being everted by one of those explosive capsules which have been mentioned above. Although microscopic in size, the threads have astonishing powers of penetration, and the poison which they carry with them, although weak in some Coelenterates, is usually strong enough to paralyze the prey suitable to each species. In the case of the most powerful stingers the poison is extremely virulent, and contact with a tentacle will produce violent pain in the human skin. The fact that the threads penetrate enables the tentacle to adhere to the prey unless its struggles are strong enough either to break them or to pull away part of the ectoderm, and in some cases there exist, in addition to the capsules with penetrating threads, others whose threads do not enter the prey but are covered with sticky material and adhere to it. The prey captured by this method is transferred by the tentacles to the mouth, which is generally very extensile and can open widely so as to engulf objects which in some cases are enormous in relation to the size of the swallower. The Coelenterate has not necessarily finished stinging the prey after it has been taken in, for in many cases there exist internal stinging organs.



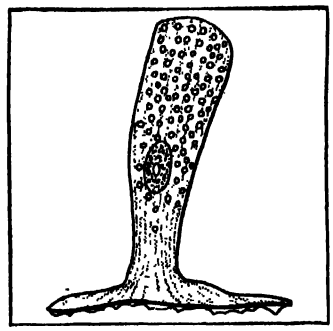
There is another method of feeding which may supplement or replace the characteristic one. Small food particles which come in contact with some part of a Coelenterate become entangled in slime secreted by that part, and these are transported by means of cilia acting in definite directions to the mouth. This method of feeding is probably the predominating one in certain species—for instance, in some sea anemones—and a good example of its working may be seen in the jellyfish *Aurelia*.

When *Aurelia* is feeding, planktonic organisms become entangled in strings of slime on the outside of the swimming-bell, and are conveyed by the movements of the bell aided by the action of cilia to the edge of the umbrella. Arrived at this point they are concentrated into eight masses at points situated at regular intervals round the margin of the bell. From time to time these masses are licked off by one or other of the four large arm-like processes which hang down under the bell round the mouth; and since each of these arms contains a groove leading directly into the mouth, the food mass is from this point onwards easily transported into the stomach. The underside of the swimming-bell also contributes to the eight food masses and the oral arms themselves collect plankton independently. This seems to be a normal mode of feeding in *Aurelia*, but at the same time it can and does, at any rate when young, catch fishes and other organisms as well as plankton.

The Food of Coelenterata.—The food of Coelenterates includes a great variety of animals—fishes and their eggs, crabs and all manner of other Crustacea, worms, molluscs, other Coelenterates, etc., not to mention the innumerable small planktonic organisms imbibed. Some Coelenterata are omnivorous, but others again will select their food more or less definitely. Certain special forms have been supposed to feed upon unicellular Algae (*Zooxanthellae*), but later work showed that these, also, are carnivorous and that the *Zooxanthellae* contained in their tissues are of importance in connection with their excretory process and are not used as food.

Digestion.—Digestion in Coelenterates is a process involving two stages. If a large object has been swallowed it is first broken up into particles and the latter are then engulfed or ingested by individual endoderm cells within which each particle becomes surrounded by a fluid-containing vacuole and there the remaining processes of digestion and absorption take place. Thus the whole process involves first *extra-cellular* digestion in the coelenteron, and then *intra-cellular* digestion in the endoderm; or if the food is small enough it may be directly ingested by endoderm-cells without previous breaking down. The details of this process vary according to the anatomy of the Coelenterate in question. In a simple case such as that of *Hydra*, the coelenteron is lined by a simple and fairly uniform layer of endoderm, not concentrated into special structures; and in such case this layer performs the double function of secreting digestive material which will break up a large prey and of ingesting the fragments so produced. In a higher form such as a sea anemone or coral the endoderm is differentiated into regions; there are definite tracts of epithelium in which gland-cells are concentrated, and these constitute together with the adjacent endoderm the main digestive area. These tracts, the mesenterial filaments, have been shown to secrete a digestive juice; and although they may also themselves ingest, in the most specialized cases the main absorptive region is not the filament itself but the endoderm on either side of it. The area of endoderm which will ingest food in such cases varies according to the size of the meal. The digestive ferments of Coelenterates are specialized for dealing with animal prey.

Nervous System.—This is of a very primitive grade in Coelenterata, and possesses neither actual nerves nor any central controlling organ. Its essential parts are the sensory cells and nerve cells of the ectoderm and endoderm, together with a network of fine fibrils connecting these cells with the muscle fibres and with each other. The nerve cells and fibrils constitute a "nerve net" which runs in the deeper part of the epithelium (fig. 7) and perhaps also penetrates the mesogloea. The net is sometimes fairly evenly distributed, sometimes better developed in one part than in another, and sometimes decidedly concentrated in given regions. It is not, as was formerly thought, a continuous network in the sense that the processes of one cell are actually fused with those of another, as it is now known that the cells are separate entities with their fibrils in contact, the junctions having the physiological properties of elementary synapses (*q.v.*). The mode of action of the network has received considerable study in the later years (*see*, for instance, the references to work by Pantin at the end of this article), but it cannot be described adequately in a few words. The behaviour of the individual nerve cells resembles that of the similar cells of higher animals more closely than was originally supposed; but the distinguishing feature of the net is its tendency to conduct impulses in all directions, in spite of which it may develop special tracts along which impulses travel rapidly for the production of certain particular responses. The net also exhibits in a high degree the phenomena known as interneural and neuromuscular facilitation (*see* the articles by Pantin referred to above).



FROM SCHNEIDER, "LEHRBUCH DER VERGLEICHENDEN HISTOLOGIE DER TIERE" (FISCHER)

FIG. 7.—PART OF THE NERVE NET OF A COELENTERATE

Many Coelenterata possess definite sense-organs. These are naturally found in the more active members of the group, that is to say the medusae; they are absent altogether in the polyps. The chief types of sense-organs are two in number, and these are described in connection with the animals possessing them, in the articles HYDROZOA and SCYPHOZOA. The first type includes organs sensitive to light and termed *ocelli*; and these structures, though often simple, may attain at their

highest development the grade of eyes (see *Charybdaea*, in SCYPHOZOA). The second type comprises organs of variable structure (*statocysts* and *tentaculocysts*) which include hard particles (*statoliths*) in their constitution, and whose function is not yet fully understood. Although they might be expected to be organs of balance this does not necessarily appear to be the case. It has been ascertained experimentally, however, that certain of these organs initiate the stimuli which produce the swimming-contractions of the bell of the medusa possessing them, and consequently control the rate of pulsation. The bell pulsates at the rate of whichever organ is initiating stimuli most rapidly at a given time. The sense organs also appear to exert an influence on the general metabolic activities of the animal.

Stinging Capsules.—The cnidoblasts with their explosive capsules or *cnidae* will now be described (fig. 9). These capsules are among the most extraordinary structures to be found in the animal kingdom, and the physiological problem presented by the question of their explosion is a difficult one. It is probable that several factors are involved, and that these are called into play in fluctuating intensity according to the structure of the capsule and cnidoblast in question. Each cnida is a refringent transparent capsule with a gelatinous or more probably fluid content. In unexploded state, the capsule contains a hollow thread (*i.e.*, a capillary tube of incredible fineness) coiled or folded up within it; and the wall of capsule and thread are continuous with one another at one pole of the capsule. The cell (*cnidoblast*) in which the capsule lies and which originally produced it commonly bears at its free surface a fine hair-like projection, known as a *cnidocil*. The contact of a foreign body suitable as food with this cnidocil ordinarily leads directly to the explosion of the capsule. On the other hand such contact does not necessarily explode the capsule. For instance the reactions of a well-fed sea anemone are not the same as those of a hungry one; the tentacles may refuse food altogether, neither the tactile nor the chemical stimuli involved producing any effect on the capsules. When, however, a capsule does explode the thread is shot forth instantaneously. Although the action is so rapid, the thread as it is ejected turns completely inside out, in the manner in which one may turn the finger of a glove; in other words it is evaginated.

FROM SCHNEIDER, "LEHRBUCH DER VERGLEICHENDEN HISTOLOGIE DER TIERE" (FISCHER)

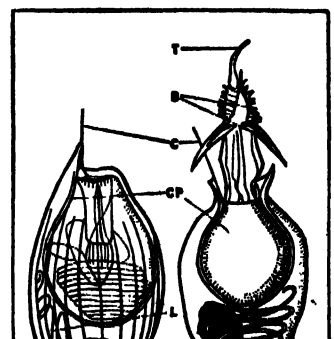


FIG. 8.—A SINGLE MUSCULO-EPITHELIAL CELL. THE CELL CONTAINS A NUCLEUS AND A SINGLE MUSCLE FIBRE

The structure of both cnidae and cnidoblasts varies greatly from one Coelenterate to another, and both may be complex. The cnidoblast possesses, in a number of cases at least, contractile fibres of varying disposition, and may also contain a coiled spring-like structure (the *lasso*) which probably resists the tearing away of the nematoblast from the tissues by a struggling prey. In a typical cnida the thread is provided with a series of spirally arranged barbs which help to fix it in the tissues of the prey, and bears with it poison which enters by the wound it has made. This kind of cnida, which is very frequent, is known as a *nematocyst*, in contrast to another type common in sea anemones and known as a *spirocyst*. The latter has no armature, but the outer surface of its evaginated thread has strongly adhesive properties, and is probably not poisonous.

True cnidae occur nowhere in the animal kingdom save in the Coelenterata. There are similar structures developed in at least two other kinds of animals (the myxosporidean Protozoa and certain nemertine worms), but they are not exactly the same; a number of other structures which have been confused with nematocysts are not actually such. The most interesting cases which have been investigated in this connection are those of certain animals in whose tissues actual Coelenterate nematocysts are present in an unexploded and functional condition. It has been conclusively shown that an animal may feed upon a Coelenterate, thus swallowing quantities of nematocysts, and that a number of these may pass unexploded through its food-canal, and may subsequently become arranged in a definite manner in its tissues. The best known instance of this is provided by certain of the Nudibranch molluscs or sea slugs. In some cases at least these stolen nematocysts appear to be of value to their host.

Nematocysts and spirocysts, which are produced by interstitial cells, are not developed in the place where they will function. In some cases this means simply that they develop in the deeper layers of the epithelium and move up to the surface as they mature. In other cases, however, a much more interesting story is involved. The capsules are here secreted by cnidoblasts far removed from the site of their ultimate explosion, and in order to bring them into the situation and orientation which will permit them to function, the cnidoblasts, which are amoeboid and possess the power of independent movement, drag their capsules between the epithelial cells (or transport them by other means) until the proper locality is reached. A most interesting example of the processes involved is supplied by the state of affairs which exists in an unusual jellyfish known as *Haliclystus*. This animal has the edge of its bell produced into eight arms, each tipped by a tuft of tentacles; and on the middle of the outside of the bell it bears a stalk by the end of which it can attach itself to seaweed and other objects. It has been found that the tentacles contain two kinds of nematocyst, and that both kinds are produced in definite parts of the ectoderm of the inner surface of the bell. It has further been discovered that the cnidoblasts containing the two kinds of capsules migrate from their nursery to the tentacles; but that on the way some of those of one pattern (and not those of the other) disappear into little ectodermal pockets which lie close to the margin of the bell. The function of the pockets appears to be that of reservoirs whence a supply of capsules may be drawn in case of special need—for instance, if the tentacles belonging to one side of the animal be cut off, new ones are regenerated and a large supply of capsules is needed to stock them; and it has been found that under such circumstances the pockets nearest to the regenerating tentacles were empty.

Reproduction.—Coelenterates reproduce their kind in a variety of ways. They produce in the manner common to animals, eggs and spermatozoa, which after union develop into new creatures. But in addition to this universal method they have an extraordinarily strong tendency toward "vegetative" or asexual modes of reproduction, and correlated with this a very marked ability to regenerate lost parts. This manner of increase is much like the ability of a strawberry-plant to produce runners. It exists under a variety of forms; sometimes an animal within the space of a few hours or less will tear itself completely in half vertically; each half will regenerate new parts and will so develop into a complete animal. This process is known as fission; it does not always take the form of actual tearing, but may result from a gradual process of constriction whereby an individual separates either completely into halves or becomes partly double. In other varieties of fission the separation into two or more parts takes place horizontally; and again, neither in vertical nor horizontal fission does it follow that the pieces formed will be at all equal in size. Equally characteristic of Coelenterates, but generally speaking of different ones, is the process known as budding (figs. 4 and 10). In this case a polyp may send out a rootlet (like the strawberry-runner) at the end of which a new polyp grows up;

or a new polyp may arise direct from the tissues of an existing one. Polyps give rise by budding to other polyps or to medusae; medusae by budding may produce fresh medusae but never polyps, these being always developed from eggs or from other polyps. The processes of regeneration which succeed certain types of asexual reproduction are both definite and interesting; and the regenerative results which arise from the cutting away of various parts of Coelenterates, or from the division of these animals into portions by cuts in different directions, provide material for a study from which much of general biological interest may be gained. Further details relating to budding and fission will be found in the articles HYDROZOA, SCYPHOZOA and ANTHOZOA, whilst for information relating to regeneration reference should be made to the article on that subject.

Commensalism and Symbiosis.—There are to be found among the Coelenterata a number of examples of those types of relationship between one organism and another which are respectively known as *commensalism* and *symbiosis*. Commensalism, as exemplified by the regular partnership which exists between certain sea anemones and hermit crabs, is well represented in the group (*see* also next section); and a number of Coelenterata contain in their tissues those unicellular symbiotic algae known as *Zooxanthellae*.

The Poison of Coelenterates.—A certain amount of work has been done on the lines of making extracts of one sort and another of the tissues of Coelenterates and injecting these into other animals in order to study the effect of the poison of the Coelenterate on the animal in question. It has been known for a long time that the poisons of certain Coelenterates are very virulent and that contact of the stinging organs with human skin may produce serious results. In the case of medusae belonging to the *Charybdaeidae* for instance, jellyfish which outstrip all others in the strength and rapidity of their swimming-movements, the stinging organs may cause intense pain after contact with the skin, and symptoms such as swelling of the legs, etc., follow; fatal results may even ensue. An investigation of particular interest has been made on the poison of *Adamsia palliata* which throws light not only on the question of Coelenterate poisons but also upon the relationship between this anemone and another animal. *Adamsia palliata* lives in permanent association with a hermit crab known as *Eupagurus prideauxi*, and apparently these two organisms never normally occur apart. The soft tail-end of the crab is protected by the anemone, which is wrapped round it like a cloak; and the mouth of the anemone lies just below that of the crab, so that meals become a communal affair. Now it is possible to make an extract containing the poison of the tentacles or other stinging organs of an *Adamsia*, and such extracts have been injected in varying strengths into a number of animals. Certain of these, for instance Cephalopod molluscs (cuttle-fishes, etc.) and other sea anemones, appear to be completely immune from the *Adamsia* poison; other animals succumb to it. It has been found that the Decapod Crustacea (crabs, etc.) are the most sensitive to it, and its action on a number of these has been studied. The following experiment is a case in point. Three shore-crabs (*Carcinus maenas*), three common hermit-crabs (*Eupagurus bernhardus*) and three of the hermits proper to *Adamsia* (*E. prideauxi*) were selected, and into the body-cavity of each was injected 0.1ml. of a filtered maceration of *Adamsia*. At the end of three minutes the *bernhardi* were completely paralyzed after a short phase of tetanization; and at the end of an hour they were dead. The shore-crabs died between five and nine hours after having exhibited the symptoms characteristic of this poison. On the other hand the *prideauxi* showed no apparent trouble; they retained all their agility and all the accustomed vivacity of their movements. At the end of 24 hours their condition was normal and they survived indefinitely. Other experiments confirm the result of this one, and the interesting fact emerges that *E. prideauxi* is immune from the poison of its anemone unless injected in inordinately large amount. Thus the association between the two animals includes a physiological as well as a morphological adaptation. It has been shown further that the serum of *E. prideauxi* is able to neutralize the *Adamsia* poison and that if a shore-crab be inoculated with *prideauxi* serum, it can afterwards withstand and recover from a dose of poison which would otherwise be fatal. It is probable that *E. prideauxi* gains its immunity in the first instance as a result of the fact that its close association with the anemone involves the constant entanglement of small portions of the latter, or of stinging cells derived from it, in the hermit's food. The intestinal content of the hermit usually contains such fragments of the anemone. Although in these experiments the poison of *Adamsia* did no harm to other anemones, yet in other cases one anemone may sting another, even of the same kind, and produce a wound which may prove fatal—so that an anemone is not necessarily immune from poison produced by its own kind. It is possible, however, that the injured animal in such cases is, to begin with, in a poor condition.

FROM KÜKENTHAL, "HANDBUCH DER ZOOLOGIE" (WALTER DE GRUYTER & CO.)

FIG. 10.—A POLYP IN PROCESS OF BUDDING

Distribution, Environment and Length of Life.—The distribution of the Coelenterata is world-wide, but the great majority are marine; a few kinds only inhabit brackish or fresh water, and these are further mentioned in the articles HYDROZOA and ANTHOZOA. The mass of Coelenterata then, inhabit one or other of the regions of the sea; and it cannot be said that they are characteristic of one kind of habitat more than of another. Many of them inhabit the littoral zone between tidemarks. Others colonize the sea-floor at greater or lesser depths, some of them occurring in extremely deep water (*e.g.*, 2,900 fathoms). The remainder are pelagic at varying depths and may live in the open sea, some of them floating and some swimming. A number of Coelenterates are perennial, living for a number of years, their length of life in some cases probably being extremely great. The best measured example of this is that of some sea anemones alive in 1945, which were known to be nearly 90 years old and possibly were much more. Other Coelenterates, on the other hand, are seasonal; many hydroids die down in winter and regenerate new polyps in spring; and many medusae live for a brief period only. Neither the tropics nor the cold regions can be regarded as the more typical habitat for Coelenterata, though it is true that corals, anemones and Siphonophores for instance, attain their maximum profusion or considerable complexity of development (sometimes both these features) in the warm seas. The variety of Coelenterates which may occur within a broadly similar environment is great, but as in the case of many other animals a certain proportion at least of the genera permanently colonizing the various available habitats show a sympathetic reaction to their environment; thus it may be expected with reason that an average anemone living at great depths will be different from a typical inhabitant of a coral-reef, and a typical mud-dweller from an ordinary adherent form. Certain single species however range in suitable habitats from the arctic to the equator, others occur both in the arctic and the antarctic; whilst some are circumpolar in distribution. With regard to the distribution of jellyfish it may be noted that their swimming powers are adapted rather for maintaining their position in the water and for moving up and down in it than for making long journeys; the main agents in their distribution are currents and tides.

Classification.—The Coelenterata are divided into three great classes, the *Hydrozoa*, *Scyphozoa* and *Anthozoa*. To these are sometimes added the *Ctenophora;* but the latter are animals which are actually very different from any Coelenterata, and the reasons which lead to this conclusion are stated in the article dealing with them. The characteristics of the three great classes of Coelenterata are also described in articles dealing with each series separately.

COELLO, ALONSO SANCHEZ (1515–1590), Spanish painter, according to some authorities a native of Portugal, was born, according to others, at Benifacio, near the city of Valencia. He studied many years in Italy; and returning to Spain in 1541 he settled at Madrid, and worked on religious themes for most of the palaces and larger churches. He was a follower of Titian, and, like him, excelled in portraits and single figures, elaborating the textures of his armours, draperies, and such accessories in a manner so masterly as strongly to influence Velazquez in his treatment of like objects. Many of his pictures were destroyed in the fires that consumed the Madrid and Prado palaces, but many good examples are yet extant, among which may be noted the portraits of the infantes Carlos and Isabella, now in the Madrid gallery, and the St. Sebastian painted in the church of San Gerónimo, also in Madrid. Coello left a daughter, Isabella Sanchez, who studied under him, and painted excellent portraits.

COELLO, ANTONIO (1611–1652), Spanish dramatist and poet, was born at Madrid and entered the household of the duke of Albuquerque. His best known plays are *El conde de Sex, El Celoso extremeño* (dramatizing one of Cervantes' *Novelas Exemplares*) and *Los Empeños de seis horas*. The latter was adapted by Samuel Tuke, under the title of *The Adventures of five Hours*, and was described by Pepys as superior to *Othello*.

COELLO, CLAUDIO (*c.* 1630–1693), Spanish painter born at Madrid, son of a well-known worker in bronze of Portuguese origin. He studied under Francisco Rizi, and was dominated at first by an overcharged, exaggerated style, which was then beginning to be admired in Madrid. He assisted his master in the execution of an altarpiece for S. Placido. He then studied and copied the works of Titian, Rubens and Van Dyck in the royal collections, to which he secured access through his friendship with the court painter D. Juan Carreño. He also profited by his friendship with Josef Donoso, who had studied seven years in Rome, and, with his co-operation, painted frescoes in some churches and palaces of Madrid. In 1671 he decorated the ceiling of the vestry in Toledo cathedral. In 1683 he was commissioned by the archbishop of Saragossa to paint frescoes in the cupola and the transept of the Augustine church. On his return to Madrid he became court painter to King Charles II., and undertook the altarpiece for the sacristy in the Escorial representing the "Transfer of the Holy Eucharist." The scene is represented as taking place in the same room in which the picture is hung. It is a fine arrangement of space in the baroque style containing some 50 life-like portraits including that of Charles II. and his prime minister. This work is his masterpiece. It is nearly allied to the realistic art of Velasquez and Carreño, and Coello here shows himself as a brilliant and strong colourist, a fine and careful draughtsman. He seems to have tried to stem the decadence, which was engulfing Spanish art. His work was universally admired, he was appointed Seneschal and his son received a pension of 300 ducats. Then Luca Giordano arrived in 1692. The preference shown by the court to the Italian favourite, hurt Coello's sensitive nature. His last work was the "Martyrdom of St. Stephen," painted for the Dominican church at Salamanca. He died on April 2, 1693, at Madrid, and was buried in the church of San Andres. He was the last important master of the great Madrid school of the 17th century.

His works are to be seen in the churches of Madrid and other cities of Spain, at the Prado, in the galleries of Munich, Budapest and Frankfurt. "The Betrothal," presented to the National Gallery, London, as by Velazquez, is perhaps an early work by Coello, who is also represented in the collections at Apsley house and Grosvenor house.

See A. de Beruete y Moret, *The School of Madrid* (1909).

COELOM AND SEROUS MEMBRANES. In human anatomy the body-cavity or coelom is divided into the *pericardium*, the two *pleurae*, the *peritoneum* and the two *tunicae vaginales*.

The *pericardium* is a closed sac in the thorax and contains the heart. Like all the serous membranes it has a visceral and a parietal layer, the former being closely applied to the heart and consisting of endothelial cells with a slight fibrous backing: to it is due the glossy appearance of a freshly removed heart. The parietal layer is double; externally there is a strong fibrous coat continuous with the other fibrous structures in the neighbourhood, while internally is the endothelial layer which is reflected from the surface of the heart, where the great vessels enter. Hence everywhere the two layers of the membrane are in contact except for a trace of fluid secreted by the serous walls.

The *pleurae* resemble the pericardium except that the fibrous outer coat of the parietal layer is not nearly as strong; it is closely attached to the inner surface of the chest walls and mesially to the outer layer of the pericardium; above it is thickened by a fibrous contribution from the scalene muscles, and forms the *dome of the pleura* which fits into the concavity of the first rib and contains the apex of the lung. The reflection of the serous layer of the pleura, from the parietal to the visceral part, takes place at the root of the lung. The upper limit of the pleural cavity reaches about half an inch above the inner third of the clavicle, while, below, it may be marked out by a line drawn from the twelfth thoracic spine to the tenth rib in the mid axillary line, the eighth in the nipple line, and the sixth at its junction with the sternum.

The *peritoneum* is a more extensive and complicated membrane; it surrounds the abdominal and pelvic viscera, and, like the other sacs, has a parietal and visceral layer. The line of reflection of these, though continuous, is very tortuous. The peritoneum consists of a *greater* and *lesser sac* which communicate through an opening (*foramen of Winslow*) and the best way of understanding these is to follow the reflections first in a vertical median (sagittal) section and then in a horizontal one, the body being supposed to be in the upright position. If a median sagittal section be studied first, and a start be made at the umbilicus (*see* fig. 1), the parietal peritoneum is seen to run upward, lining the anterior abdominal wall, and then to pass along the under surface of the diaphragm till its posterior third is reached; here there is a reflection on to the liver, forming the anterior layer of the *coronary ligament* of that viscus, while the membrane now becomes visceral and envelops the front of the liver as far back as the transverse fissure on its lower surface; here it is reflected on to the stomach forming the anterior layer of the *gastro-hepatic* or *lesser omentum*. It now covers the front of the stomach, and at the lower border runs down as the anterior layer of an apron-like fold, the *great omentum*, which sometimes reaches as low as the pubes; then it turns up again as the posterior or fourth layer of the great omentum until the transverse colon is reached, the posterior surface of which it covers and is reflected, as the

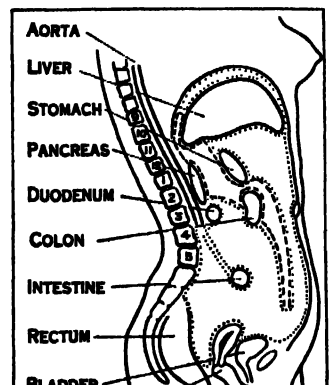

FIG. 1.—VERTICAL MEDIAN SECTION OF ABDOMEN TO SHOW ARRANGEMENT OF THE PERITONEUM
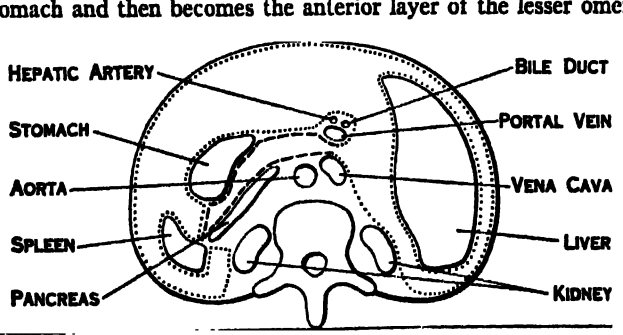
The peritoneum is indicated by a dotted line for the greater sac and a broken line for the lesser sac

posterior layer of the *transverse mesocolon* to the lower part of the pancreas; after this it turns down and covers the anterior surface of the third part of the duodenum till the posterior wall of the abdomen is reached, from which it is reflected on to the small intestine as the anterior layer of the *mesentery*, a fold varying from 5 to 8 in. between its attachments. After surrounding the small intestine it becomes the posterior layer of the mesentery and so again reaches the posterior abdominal wall, down which it runs until the rectum is reached. The anterior surface of this tube is covered by peritoneum to a point about 3 in. from the anus, where it is reflected on to the uterus and vagina in the female and then on to the bladder; while in the male, on the other hand, the reflection is directly from the rectum to the bladder. At the apex of the bladder, after covering the upper surface of that organ, it is lifted off by the urachus and runs up the anterior abdominal wall to the umbilicus, from which the start was made. All this is the greater sac. The tracing of the lesser sac may be conveniently started at the transverse fissure of the liver, whence the membrane runs down to the stomach as the posterior layer of the lesser omentum, lines the posterior surface of the stomach, passes down as the second layer of the great omentum and up again as the third layer, covers the anterior surface of the transverse colon and then reaches the pancreas as the anterior layer of the transverse mesocolon. After this it covers the front of the pancreas and in the middle line of the body runs up below the diaphragm to within an inch of the anterior layer of the coronary ligament of the liver; here it is reflected on to the top of the Spigelian lobe of the liver to form the posterior layer of the coronary ligament, covers the whole Spigelian lobe, and so reaches the transverse fissure.

This section, therefore, shows two completely closed sacs without any visible communication. In the female, however, the great sac is not absolutely closed, for the Fallopian tubes open into it by their minute *ostia abdominalia*, while at the other ends they communicate with the cavity of the uterus and so with the vagina and exterior.

A horizontal section through the upper part of the first lumbar vertebra will, if a fortunate one (*see* fig. 2), pass through the foramen of Winslow and show the communication of the two sacs. A starting-point may be made from the mid-ventral line and the parietal peritoneum traced round the left side of the body wall until the outer edge of the left kidney is reached; here it passes in front of the kidney and is soon reflected off on to the spleen, which it nearly surrounds; just before it reaches the hilum of that organ, where the vessels enter, it is reflected on to the front of the stomach, forming the anterior layer of the *gastro-splenic omentum;* it soon reaches the lesser curvature of the stomach and then becomes the anterior layer of the lesser omentum, which continues until the bile duct and portal vein are reached at its right free extremity; here it turns completely round these structures and runs to the left again, as the posterior layer of the lesser omentum, behind the stomach and then to the spleen as the posterior layer of the gastro-splenic omentum. From the spleen it runs to the right once more, in front of the pancreas, until the inferior vena cava is reached, and this point is just behind the portal vein and is the place where the lesser and greater sacs communicate, known as the foramen of Winslow. From this opening the lesser sac runs to the left, while all the rest of the peritoneal cavity in the section is greater sac. From the front of the vena cava the parietal peritoneum passes in front of the right kidney and round the right abdominal wall to the mid-ventral line. The right part of this section is filled by the liver, which is completely surrounded by a visceral layer of peritoneum, and no reflection is usually seen at this level between it and the parietal layer. Some of the viscera, such as the kidneys and pancreas, are retro-peritoneal; others, such as the small intestines and transverse colon, are surrounded, except at one point where they are attached to the dorsal wall by a *mesentery* or *mesocolon* as the reflections are called; others again are completely surrounded, and of these the caecum is an example; while some, like the liver and bladder, have large uncovered areas, and the reflections of the membrane form ligaments which allow considerable freedom of movement.



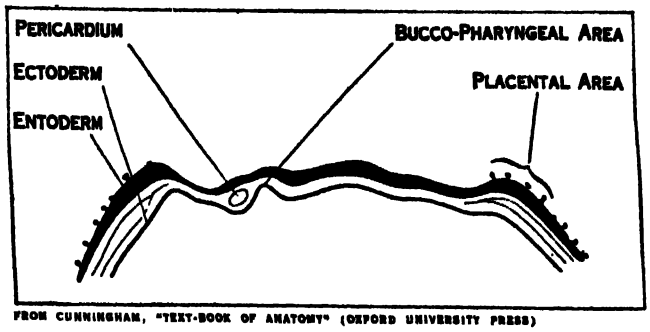


FIG. 2.—HORIZONTAL SECTION THROUGH UPPER PART OF FIRST LUMBAR VERTEBRA, SHOWING ARRANGEMENT OF THE PERITONEUM

FROM CUNNINGHAM, "TEXT-BOOK OF ANATOMY" (OXFORD UNIVERSITY PRESS)

FIG. 3.—LONGITUDINAL SECTION SHOWING THE DIFFERENT AREAS OF THE BLASTODERMIC VESICLE IN EARLY DEVELOPMENT OF THE OVUM

The *tunica vaginalis* is the remains of a peritoneal pocket which descends into the scrotum during foetal life before the testis itself descends. After the descent of the testis the upper part usually becomes obliterated, while the lower part forms a serous sac which nearly surrounds the testis. The parietal layer lines the inner wall of its own side of the scrotum.

Embryology.—As the mesoderm spreads over the embryo it splits into two layers, the outer of which (*somatopleure*) lines the parietal or ectodermal wall, while the inner lines the entoderm (*splanchnopleure*); between the two is the coelom. The pericardial area is early differentiated from the rest of the coelom and at first lies in front of the neural and bucco-pharyngeal area; here the mesoderm stretches right across the mid-line, which it does not in front and behind. As the head of the embryo is formed the pericardium is gradually turned right over, so that the dorsal side becomes the ventral and the anterior limit the posterior; this will be evident on referring to figs. 3 and 4.

The two primitive aortae lie at first in the ventral wall of the pericardium, but with the folding over they come to lie in the dorsal wall and gradually bulge into the cavity as they coalesce to form the heart, so that the heart drops into the dorsal side of the pericardium and draws down a fold of the membrane called the *dorsal mesocardium*. In mammals A. Robinson (*Jour. Anat. and Phys.*, xxxvii. 1) has shown that no ventral mesocardium exists, though in more lowly vertebrates it is present. Laterally the pericardial cavity communicates with the general cavity of the coelom, but with the growth of the Cuvierian ducts (*see* development of veins) these communications disappear. Originally the mesocardium runs the whole length of the pericardium from before backward, but later on the middle part becomes obliterated.

Just behind the pericardium and in front of the umbilicus, which at first are close together, the mesoderm forms a mass into which the developing lungs push bag-like protrusions of the coelom. These lose their connection with the rest of the coelom, as the diaphragm develops, and become the pleural cavities. The remainder of the coelom persists as the peritoneum. At first the stomach and intestine form a straight tube, connected to the dorsum of the embryo by a *dorsal mesentery* and to the mid-ventral wall in front of the umbilicus by a *ventral mesentery*. Into the ventral mesentery the liver grows as diverticula from the duodenum, so that some of the mesentery remains as the *falciform ligament* of the liver and some as the lesser omentum. Into the

dorsal mesentery the pancreas grows, also as diverticula, from the duodenum, while the spleen is developed from the mesoderm contained in the same fold. As the stomach turns over and its left side becomes ventral, the dorsal mesentery attached to it is pulled out, so that part forms the great omentum and part the gastro-splenic omentum. When the caecum is formed as a diverticulum from the intestine it is close to the liver but gradually travels down into the right iliac fossa. This passage to the right is accompanied by a throwing over of the duodenal loop to the right, so that the right side of its mesentery becomes pressed against the dorsal wall of the abdomen and obliterated. This accounts for the fact that the pancreas and duodenum are only covered by peritoneum on their anterior surfaces in man. The formation of the lesser sac is due to the turning over of the stomach to the right, with the result that a cave is formed behind it. Originally the whole colon had a *dorsal mesocolon* continuous with the mesentery, but in the region of the ascending and descending colon this usually disappears and these parts of the gut are uncovered by peritoneum posteriorly. The transverse mesocolon persists and at first is quite free from the great omentum, but later, in man, the fourth layer of the great omentum becomes continuous with the posterior layer of the transverse mesocolon.

Comparative Anatomy.—In *Amphioxus* the coelom is developed in the embryo as a series of bilateral pouches from the sides of the alimentary canal; these are therefore entodermal in their origin, as in *Sagitta* and the Echinodermata among the invertebrates. In the adult the coelom is represented by two dorsal canals communicating with a ventral canal by means of branchial canals which run down the outer side of the primary gill bars. Into the dorsal canals the nephridia open. In the intestinal region the coelom is only present on the left side.

In the higher vertebrates (*Craniata*) the coelom is developed by a splitting of the mesoderm into two layers, and a pericardium is constricted off from the general cavity. In all cases the ova burst into the coelom before making their way to the exterior, and in some, e.g., *Amphioxus*, lamprey (Cyclostomata), eels and mud-fish (Dipnoi), the sperm cells do so too. The Cyclostomata have a pair of *genital pores* which lead from the coelom into the urino-genital sinus, and so to the exterior.

In the Elasmobranch fish there is a *pericardio-peritoneal canal* forming a communication between these two parts of the coelom;

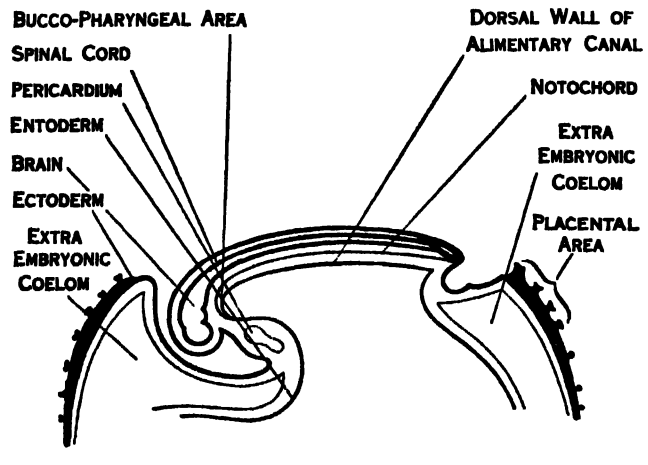

FIG. 4.—LONGITUDINAL SECTION SHOWING RELATION OF PARTS TO SEROUS MEMBRANES IN THE EARLY DEVELOPING EMBRYO

also a large common opening for the two oviducts in the region of the liver, and two openings (*abdominal pores*) on the surface close to the cloacal aperture. In the Teleostomi (Teleostean and Ganoid fish) abdominal pores are rare, but in most Teleostei (bony fish) the ova pass directly down oviducts, as they do in arthropods, without entering the peritoneal cavity; there is little doubt, however, that these oviducts are originally coelomic in origin. In the Dipnoi (mud-fish) abdominal pores are found, and probably serve as a passage for the sperm cells, since there are no vasa deferentia. In fishes a complete dorsal mesentery is seldom found in the adult; in many cases it only remains as a tube surrounding the vessels passing to the alimentary canal.

In the Amphibia, Reptilia and Aves, one cavity acts as pleura and peritoneum, though in the latter the lungs are not completely surrounded by a serous membrane. In many lizards the comparatively straight intestine, with its continuous dorsal mesentery and ventral mesentery in the anterior part of the abdomen, is very like a stage in the development of the human and other mammalian embryos. In the mammalia the diaphragm is complete (*see* DIAPHRAGM) and divides the pleuroperitoneal cavity into its two constituent parts. In the lower mammals the derivatives of the original dorsal mesentery do not undergo as much fusion and obliteration as they do in adult man; the ascending and descending mesocolon is retained, and the transverse mesocolon contracts no adhesion to the great omentum. It is common, however, to find a fenestrated arrangement of the great omentum which shows that its layers have been completely obliterated in many places.

In those animals, such as the rabbit, in which the testes are sometimes in the scrotum and sometimes in the abdomen, the communication between the peritoneum and the tunica vaginalis remains throughout life.

BIBLIOGRAPHY.—Full bibliography in Quain's *Anatomy*.

COELOMATA, a zoological term denoting those animals that have a true coelom, *i.e.*, a space within the entomesoderm. Animals with no space between the digestive canal and body wall, as the flatworms (*Platyhelminthes*), are termed Acoelomata, and those in which this space is not a true coelom are called Pseudocoelomata.

COELOSTAT, a mirror driven by clock-work so as to reflect continually the same region of the sky into the field of view of a fixed telescope. The mirror is mounted so as to rotate about an axis in its own plane which points to the pole of the heavens, and is driven at the rate of one revolution in 48 (sidereal) hours. The image of a star seen in the mirror is then stationary. The device is particularly useful in eclipse expeditions when elaborate equatorial mounting of the telescopes is impossible. Other instruments for somewhat similar purposes are the heliostat and siderostat (*q.v.*).

COEN, JAN PIETERSZOON (1587–1630), fourth governor-general of the Dutch East Indies, was born at Hoorn, and spent his youth at Rome in the house of the famous merchants the Piscatori. In 1607 he sailed from Amsterdam to the Indies as second commercial agent, and remained away four years. In 1612 he was sent out at the head of a trading expedition. In 1613 he was made a councillor and director-general of the East Indian trade. Afterwards he became president at Bantam, and on Oct. 31, 1617, he was promoted in succession to Laurens Reaal to the post of governor-general. To his vigour and intrepidity the Dutch in no small measure owed the preservation and establishment of their empire in the East. He took and destroyed Jacatra, and founded on its ruins the capital of the Dutch East Indies, to which he gave the name of Batavia. In 1622 Coen obtained leave to resign his post and return to Holland, but in his absence great difficulties had arisen with the English at Amboina (the so-called massacre of Amboina), and in 1627 under pressure from the directors of the East India Company he returned as governor-general to Batavia. In 1629 he was able to beat off a formidable attack of the sultan of Mataram, sometimes styled emperor of Java, upon Batavia.

COENWULF (d. 821), king of Mercia, successor of Ecgfrith, son of Offa, in 796. In 798 he invaded Kent, imprisoned Eadberht Praen, and made his own brother Cuthred king. On Cuthred's death (807) Coenwulf seems to have taken Kent into his own hands. He abolished the archbishopric of Lichfield, probably before 803, as the Hygeberht who signed as an abbot at the council of Cloveshoe in that year was presumably the former archbishop. Coenwulf appears from the charters to have had a long dispute with Wulfred of Canterbury, who was consecrated in 806. It was probably only settled in 825, when the lawsuit of Cwoenthryth, his daughter, with Wulfred was terminated. He died in 821 and was succeeded by his brother Ceolwulf I.

See Earle and Plummer's edition of the Anglo-Saxon Chronicle,

796, 819 (Oxford, 1892); W. de G. Birch, *Cartularium Saxonicum*, 378 (1885–93).

COERCION was described by Mr. Justice Peterson (in *Hodges* v. *Webb*, 2 Ch. 70, 1920) as involving "something in the nature of negation of choice." Its principal significance in law is as one of the forms of undue influence that will invalidate gifts, whether testamentary or made between living people. "The influence which will set aside a will must amount to force and coercion, destroying free agency" (*see* Sir E. V. Williams, *Law of Executors*, 12th ed., p. 32 [London, 1930]). It would, as such, be a form of duress sufficient for the annulment of a marriage. In the sphere of criminal law, coercion excuses a participation in crime if this is induced by sheer physical force, though threats are not held to excuse: the coercion must amount to physical subjection. By s. 47 of the Criminal Justice act, 1925, on a charge against a wife for any offense other than treason or murder, it is a good defense to prove that the offense was committed in the presence, and under the coercion, of the husband.

(W. T. Ws.)

COEUR, JACQUES (*c.* 1395–1456), French trader, was neither an economist nor a statesman but an ingenious businessman. He was born at Bourges, a town of drapers and merchants, where his father was a skinner. About 1429 he formed a commercial partnership with two brothers named Godart; but he was compromised by a fraudulent speculation in coinage, in the contracting for which he had taken a share. In 1432 he initiated himself into the Levant trade, sailing from Narbonne on a ship belonging to merchants of Montpellier; Bertrandon de la Broquière, equerry of Philip the Good, duke of Burgundy, met him at Damascus. On his return his career soon became brilliant. He was master of the mint in Paris in 1436 and *argentier du roi* (steward of the royal expenditure and banker of the court) three years later. He became a member of the king's council (1442), then commissioner to the estates of Languedoc (1441–51) and inspector general of taxes (*visiteur général des gabelles*) for Languedoc (1447). Jacques Coeur inspired the *ordonnances* issued between 1435 and 1451 to withdraw the money that had been stamped with rival French and English superscriptions during the war. The king, Charles VII, charged him with diplomatic missions: in 1447, Jean de Villages, his nephew, obtained from the sultan of Egypt certain privileges for French merchants and also the right to consular representation; and Jacques Coeur himself managed to maintain good relations with Genoa and won the favour of Pope Nicholas V by his zeal to promote the abdication of the antipope Felix V. In 1449 Jacques Coeur lent the king the money necessary for the recovery of Normandy and entered Rouen with him apparelled no less magnificently than he. He was at the height of his glory. Ennobled in 1441, he managed the marriage of his daughter with a nobleman, got his brother made bishop of Luçon and saw his son archbishop of Bourges. He possessed about 40 manors and built a palace at Bourges which remains one of the finest monuments of Gothic domestic architecture in France.

Jacques Coeur's businesses were various but connected. Their basis was Levantine trade; the pope had authorized him to trade with the infidels. At Montpellier, the heart of his activity, he built a house (the *loge*) to which were delivered the spices brought by his seven galleys in exchange for scarlet cloth to the taste of the Levantines. All the chief cities of western Europe supplied and consumed his wares. At Barcelona, Avignon, Lyons, Paris, Limoges, Rouen and Bruges, Jacques Coeur had his factors; at Tours was the warehouse of the "Argenterie"; and the end of the Hundred Year's War facilitated relations with England and Scotland. Jacques Coeur competed with the Italian ports. At the end of his career he used the port of Marseilles. To sustain his enterprises, Jacques Coeur acquired much land and property, used his connections and his political position and received gratifications from the towns and the estates of Languedoc, whose interests he defended. The usual silver money necessary for trading in Levant was provided by the mines of Beaujolais and the Lyonnais that the king had granted to him.

Other merchants, however, were jealous of the quick progress of Jacques Coeur. His debtors, numerous at the court, resolved to disgrace him. He was accused of having poisoned Agnes Sorel, the king's mistress who had died in 1450; and he was charged with speculation and extortion. Arrested in July 1451 and confined for two years, he was condemned to do public penance for his fault and to remain a prisoner until he should have paid a very heavy sum; and all his possessions were confiscated. He would have remained a prisoner if Jean de Villages had not arranged his escape to Beaucaire and thence to Marseilles, Nice, Pisa and Rome, where the pope received him. But a year later on Nov. 25, 1456, he died at Chios, whither he had gone in command of the fleet sent by Pope Calixtus II to relieve Rhodes.

Louis XI, in reaction against his father, was to consider Jacques Coeur's rehabilitation, to return some of his property to his family and, by taking his agents into his service, to revive the enterprises that he had initiated.

(MI. M.)

COEUR D'ALENE, a tribe of American Indians who occupied the heavily forested area around Coeur d'Alene lake and the western slope of the Bitterroot mountains, Ida. They were one of the larger tribes of the Plateau culture area. Being relatively near the Great Plains they were subjected to influences from that area but few foreign traits were accepted. They clung tenaciously to the typical Plateau traits of democracy, pacifism and devotion to the guardian spirit religion.

They spoke a language of the Salish stock but many were bilingual, the second language being that of their southern neighbours, Nez Perce.

Various folk etymologies for the name Coeur d'Alene have been suggested but none is demonstrably correct. They call themselves by a tribal name which may be related to the term used by Lewis and Clark, Skeet-so-mish. The explorers did not visit the tribe but obtained information regarding them from the Nez Perce. They estimated the population at 2,000. Their maps show the location of the tribe and of Coeur d'Alene lake which they called Waytom.

No treaty was ever made with these Indians. In 1873 the United States simply took possession of their land, except for a reservation which was set aside by executive order. In 1892, when gold and other ores were discovered there, the reservation was reduced in size by act of congress.

Ray, "Plateau," *Anthropological Records*, vol. 8, no. 2 (1942); Gladys Reichard, "Coeur d'Alene," *Handbook of American Indian Languages*, ed. by F. Boas, vol. 3 (New York, 1939).

(V. F. R.)

COEUR D'ALENE, a city of Idaho, U.S., 33 mi. E. of Spokane, at the outlet of Lake Coeur d'Alene; the county seat of Kootenai county. It is on federal highways 10 and 95, and is served by the Northern Pacific, Chicago, Milwaukee, St. Paul and Pacific, Spokane International and Great Northern railways, also by air and bus. The population was 12,198 in 1950, and 10,049 in 1940 by the federal census.

It is in the rich lumbering, mining and agricultural region known as the "inland empire." The city has several large lumber mills and smaller manufacturing plants. It was settled about 1880, and incorporated in 1889.

COFFEE. The discovery of coffee is quite generally accredited to Africa, although earliest cultivation is traced to south-

ern Arabia. Coffee grew in Africa only in a wild state until fairly modern times, when it began to be developed there (about 1878) on a production basis by British interests. Never an important factor in the world coffee market, even through the first quarter of the 20th century, the growth of coffee in Africa approximately doubled in the decade 1929–39, and doubled again in the next 15 years to a point where, in the marketing year 1953–54, Africa accounted for approximately one-sixth of the world's exportable production.

Coffee probably derives its name from the original Arabic *qahwah*, indirectly through its Turkish form *kahveh*, although some etymologists connect it with the name Kaffa, a town in southwest Ethiopia (Abyssinia) reputed to be the birthplace of coffee. Through the ages the Arabian primitive root shows influences in whatever word has come to mean coffee in all tongues, according to the pronunciation of each language, as: Bohemian, *kava;* Chinese, *kai-fey;* Danish and Swedish, *kaffe;* Dutch, *koffie;* Finnish, *kahvi;* French, Spanish and Portuguese, *café;* German, *Kaffee;* Greek, *kaféo;* Hungarian, *kavé;* Italian, *caffè;* Japanese, *kéhi;* Latin (scientific), *coffea;* Persian, *qéhvé;* Polish, *kawa;* Rumanian, *cafea;* Russian, *kophe.*

History.—The origin of coffee is vague and obscure, but its history is rich in legend. One of the most accepted tales surrounding the discovery of coffee about A.D. 850 is that of Kaldi, an Arabian goatherd. Bewildered by the queer antics of his flock, Kaldi is supposed to have eaten berries of the evergreen bush on which the goats were feeding and, overjoyed at the feeling of exhilaration which he experienced, has been pictured in legend as dashing off in excitement to proclaim his great find to the world.

The physiological action of coffee in dissipating drowsiness was soon discovered and taken advantage of in connection with the prolonged religious service of the Mohammedans, but the strictly orthodox or conservative section of the priesthood claimed that it was an intoxicating beverage and, therefore, prohibited by the Koran. Severe penalties were threatened upon those disposed to its use. Nevertheless, coffee drinking spread rapidly among Arabian Mohammedans, and its growth and use became general in Arabia.

The early record of coffee in Europe, where it was introduced into one country after another during the 16th and 17th centuries, is filled with accounts of its use as a religious, political, and medical potion, its ups-and-downs in favour, its persecution, prohibition or approval. It is interesting to note that most of the attention given to coffee in the music and literature of that day was in support or defense of coffee and its "soul-stirring attributes," rather than critical. One of the most unique contributions to the good of coffee in music was Johann Sebastian Bach's "Coffee Cantata" (published in 1732), which portrayed "the protest of the fair sex" against the then existing propaganda in Germany for abstinence from coffee by women because "many doctors claimed its use provoked sterility."

Coffee gained its first real popularity as a beverage in the coffeehouses of London, which became centres of political, social and literary influence. The wits, philosophers and writers of the day warmed their hearts and loosened their tongues over the steaming cup. The first London coffeehouse was established in (or about) 1652 "at St. Michael's Alley in Cornhill" by one Pasqua Rosée and a "quarreling partner" named Bowman, from whom Rosée soon parted.

In the first known coffee advertisement, a handbill produced in 1652 (original in the British Museum), Pasqua Rosée proclaimed that coffee "quickens the spirits, and makes the heart lightsome . . . is good against sore eyes . . . excellent to prevent and cure the dropsy, gout, and scurvy . . . neither laxative nor restringent."

Continental Europe, too, became well implanted with the idea of coffee, and the coffeehouse flourished in most of these countries later in the 17th century. In the major cities of North America (Boston, New York and Philadelphia), coffeehouses also became popular, starting about 1689. The Merchants' Coffeehouse, established in New York in 1737, is claimed by some authorities to have been the "birthplace of the American Union."

Capt. John Smith, the founder of Virginia, is said to have been the first to bring knowledge of coffee to America in 1607, but it is not certain that he actually carried coffee with him, nor is there a definite "first date" for coffee's appearance in North America. It is not found in the records that there was coffee aboard the Mayflower (1620), nor proof that the Dutch brought coffee from Holland to New Amsterdam (New York) in the early or mid-17th century. It is known, however, that the first licence to sell coffee in the United States was issued to a Dorothy Jones of Boston in 1670.

Until toward the close of the 17th century, the world's rather limited supply of coffee was obtained almost entirely from the province of Yemen in southern Arabia. But, with the increasing popularity of the beverage, the propagation of the plant spread rapidly from the southern parts of Arabia to Ceylon (1658), to Java and other islands of the Netherland Indies starting about 1696, Haiti and Santo Domingo in 1715, Dutch Guiana (Surinam) in 1718, thence throughout the tropical countries of the new world. To date a few . . . Brazil, 1727; Jamaica, 1730; Cuba, 1748; Puerto Rico, 1755; Costa Rica, 1779; Venezuela, 1784; Mexico, 1790; Colombia, late 18th century; but not in El Salvador until 1840. Coffee growing started in the Hawaiian Islands (Kona district, Island of Hawaii) in 1825.

One of the most dramatic stories of bringing coffee to the new world is that of Gabriel Mathieu de Clieu, a young French naval officer assigned as captain of infantry at Martinique, a small island in the Lesser Antilles. In 1723 (some authorities set the date as 1720), De Clieu, on a visit to France, became determined to carry the cultivation of coffee to Martinique, having heard of the Dutch success in transplanting coffee from Arabia to the East Indies and realizing that similar climatic conditions existed in Martinique. The few coffee plants then being cultivated in Paris were guarded in the royal hothouse of Louis XV. Because De Clieu's motive was a patriotic one, he was able to enlist the aid of M. de Chirac, the king's "physician-in-ordinary," in obtaining one (some writers say two or three) of the precious plants. His trip across the Atlantic was not an easy one for, what with the time consumed in escaping capture by pirates and floundering through violent storms, the ship's supply of water ran so low as to be rationed.

In his own papers, De Clieu recorded that for more than a month he was obliged to share his scanty ration of water with his tiny coffee plant (he refers to only one) "upon which my happiest hopes were founded and which was the source of my delight." After trial and tribulation, De Clieu's precious little tree was finally planted in Martinique and carefully nursed to its first harvest of coffee cherries, from the seeds of which a big majority of the coffee plants in the Americas are said to be descended. By 1777, three years after the death of the zealous De Clieu, there were nearly 19,000,000 coffee trees in Martinique.

By the 20th century, coffee had become responsible in a large measure for the income and livelihood of many countries lying between the Tropic of Capricorn and the Tropic of Cancer. Although practically every country within this area around the earth produces some coffee, the concentration of production has centred in the western hemisphere. The largest supplies of green coffee come from South and Central America, a high percentage of the world's total being produced in Brazil alone.

Botany of Coffee.—The genus *Coffea,* to which the common coffee tree belongs, contains 25 or more species in the tropics of the old world, most of which grow only wild.

Of the various species, *Coffea arabica* makes up the bulk of world production. Others commercially known are *C. liberica, C. stenophylla* and *C. robusta.*

The common Arabian coffee shrub (*C. arabica*) is an evergreen plant which under natural conditions may grow to a height of 30 ft. or more. But for commercial purposes, particularly in countries where coffees are picked by hand, the trees are usually kept, by topping, to heights under 15 ft., which gives more easy access for harvesting. Leaves of the coffee tree resemble laurel in form (oblong-ovate-acuminate, 4 to 6 in. in length, 1½ to 2½ in. wide) and have a deep rich green colour and a waxy-looking surface.

Flowers of the coffee tree, which are produced in dense clusters in the axils of the leaves, have a five-toothed calyx, a tubular five-parted corolla, five stamens and a single bifid style. Coffee trees in blossom are things of beauty, but the white jasmine-like flowers last only a few days. Their disappearance is followed by clusters of green cherries which advance through various stages of green and golden brown until fully ripe, when they are a bright red, similar in colour and shape to ordinary fruit cherries, although somewhat less plump and slightly elongated.

The red outside covering of the coffee cherry is a thick pulpy skin. Inside is a layer of yellowish jelly-like substance that completely surrounds the two beans or berries, which lie with their flat faces together, similar to the two halves of a peanut. Each bean or berry is enclosed in a membranous endocarp, commonly called the "parchment," which is brittle when dried. Inside this, completely surrounding each individual coffee bean, is a delicate spermoderm (seed-skin) commercially called the "silver skin." Malformation in coffee cherries frequently results in their containing only a single bean, which is not flat on one side, but completely circular. Such beans are called "pea-berry" coffee. The seeds or beans of the coffee cherry are of a soft, semitranslucent, bluish or greenish colour, hard and tough in texture.

Cultivation and Preparation of Green Coffee.—Primitive methods were used in the production of coffee for many years, but by the 20th century the large commercial producers were using intensive cultivation methods, giving the same care to preparing their plantations and attending their trees as do growers of grains and fruits. By the middle of the 20th century, most of the coffee-producing countries, particularly in the western hemisphere, had made great advances in the study of soil erosion and in the adoption of modern practices in fertilization and use of insecticides in a continuing effort to obtain the maximum production of quality coffee from a plantation of given size.

The coffee tree is not free of destructive pests and plant diseases. The Ceylon coffee-leaf disease (*Hemileia vastatrix*), a fungoid growth which appeared in Ceylon in 1869 and spread throughout the coffee-growing sections of the eastern hemisphere (found also in almost every coffee-producing country), is at least partially to blame for having once destroyed the coffee industry of the old world. Insects and fungi of various types are the cause of most concern to coffee growers. The *stephanodores* (coffee-bean borer, referred to in Brazil as the "coffee plague" or *broca*), coffee "leaf-miner," Mediterranean fruit fly, and various forms of root disease are among the worst and most common. It is only through rigorous and continuous effort on the part of growers that they are kept under reasonable control, mostly through the use of modern insecticides. Research laboratories and technical stations have been established in the larger producing countries for the purpose of furthering the science of coffee-growing—increasing the rate of yield per tree, creating new and improved techniques for fighting leaf rust and the other forms of infestation mentioned and, hopefully, developing of a frost-resistant coffee tree.

In 1954 the United States government, recognizing the need for greater world production of coffee to meet the requirements of the continually-growing population of the United States (as well as the increasing demand of other countries of the world), started to develop through its Foreign Operations administration an expanded program of providing technical assistance to the coffee-producing countries of the western hemisphere in the establishment and expansion of research and training facilities. At the time it was indicated that similar aid would be made available to other parts of the world where coffee was already being produced or where climatic and soil conditions might favour attempts to grow coffee on a commercial scale.

Cultivation of the coffee plant over a period of a few hundred years has brought about considerable variation in local types as a result of climatic and soil conditions. The colour of coffee beans after preparation may differ considerably as to shade, and variations in size and shape of the beans make it possible to differentiate commercial types by appearance, although these characteristics distinguishable to the eye are not always indicative of quality "in the cup." In general, it may be said that the greatest differences in the quality of the coffee bean are produced by altitude—the higher the altitude, up to the limit of cultivability, the milder the product. High-altitude coffee beans are usually "mild" in character, and this mildness may be translated into terms of aromatic substance, which has much to do with contributing to the pleasurable aroma and taste of the beverage.

Coffee is grown under varying weather conditions at altitudes from 1,500 to 6,000 ft., but it is more or less generally conceded that the finest coffees usually come from the higher elevations—3,000 to 6,000 ft. Coffee requires a warm and humid climate, preferably with the sun on the plant only part of the day, which perhaps explains why hilly or mountainous countries are preferred for planting of trees. Desirable temperature averages 65° F. to 75° F. the year around, although coffee grows well in some places where greater variations occur (over 80° F. or under 60° F.). It should be noted that in tropical countries elevations up to 6,000 ft. or more are not accompanied by the extremes of low temperature found at such elevations in the northern latitudes, although frost-producing temperatures have been recorded in some coffee countries at infrequent intervals.

Coffee trees are planted with great regularity but become so dense after a few years that they almost appear to be growing wild. In the fore part of the 20th century, the trend was toward closer pruning of coffee trees to permit passageway and more easy access at time of picking. The coffee tree begins to produce a small number of cherries at the age of three, but on the average it is the fifth year before a tree comes into full bearing. It may continue to yield profitably for as long as 50 to 60 years, although 25 to 30 years is average, and many growers prefer to replace trees after 12 to 15 years, which makes for better quality and higher yield.

The steps involved in the cultivation and processing of green coffee differ somewhat from country to country, and from locality to locality, but the over-all procedure may be summarized in a very general way. Coffee trees are propagated either from seeds or from slips. In the latter case, a unique transplanting method is used which consists of bending down the lower branches of the tree and burying the tops in the earth. After about four months, roots form and the new growth starts.

Propagation from seeds is usually done in carefully prepared nursery beds. Seeds, selected from trees of known productivity in quality and quantity, are usually planted about an inch apart, in rows marked off in the nursery beds. To protect the tender shoots from too much sun as they come through the ground, nursery beds must have a shade covering. This is usually constructed from various kinds of brush or other tropical growth. When seedlings are four to six months old they have to be transplanted to allow more room for development of the plants that are healthy and virile. At about 18 months, when the plants are approximately 20 in. high, they are transplanted for the last time to whatever permanent planting spot has been selected. As the coffee trees continue to grow and begin to reach maturity they require more and more sunshine for proper development and ripening of the cherries, so frequent pruning of shade trees among which they have been planted is necessary.

In some producing countries, coffee cherries are allowed to ripen to a point where they shrivel and begin to dry on the trees and are then shaken off onto large canvasses. The higher grades of coffee, however, are picked when the cherries are at the desired stage of ripeness. Picking is done by hand in a very selective manner. Trees are not stripped. Only the ripe cherries are removed, and it takes several pickings before a crop is completely harvested. In some countries the harvesting is entirely seasonal, while in others it is almost a year-round process, several crops being produced each year. Picking is done by men, women and children. Under good conditions, a fair day's pick is from 100 to 125 lb. of coffee cherries. It takes about 5 lb. of cherries to make 1 lb. of green coffee beans, so, in terms of usable coffee, it might be said that a picker's capacity is from 25 to 30 lb. a day. On the average, a coffee tree will produce from 1½ to 2 lb. of green coffee beans a season; thus a plantation must be of a rather extensive size

to produce tonnage of any great consequence.

Coffee may be prepared by either a "dry" or a "wash" process. By the "dry" method, sometimes called "unwashed" or "natural," the coffee cherries are washed and spread out on cement floors in the air and sun to dry. After drying, the coffee is repeatedly run through fanning and hulling machines to remove the hulls, dried pulp and parchment, and then is subjected to further cleaning by machines which remove portions of the silver skin.

The "wash" process is quite different. The cherries are first put through a pulping machine which breaks them open and virtually squeezes the beans right out of the mass of pulpy skin. Then the beans go into large tanks where they are left for about 24 hours. Slight fermentation takes place in the jelly-like substance, which the coffee grower calls "honey." This fermentation loosens the honey so it can easily be removed by thorough washing back and forth through several hundred feet of washing canals. After washing, the coffee is spread out in patios to dry. It takes two to three weeks in the sun for the coffee to become thoroughly dried, and during this time it must be continuously turned over and over so that every bean will receive its share of tropical warmth. When climatic conditions do not permit drying in the sun, mechanical means are employed. Warm air is circulated through the coffee as it revolves in a large perforated drum. When the desired stage of drying has been reached, the coffee beans are put through hulling and polishing machines which crack and remove the brittle parchment and silver skin.

In the case of the highest quality coffees, there is then a careful hand inspection to remove imperfect beans, which is the final step before packing the coffee in bags for shipment to the coffee ports of the world. (In Brazil, coffee is sacked in 60-kg. bags—132.276 lb. In other countries, the shipping unit may vary from about 150 to 165 lb., and in a few instances may run as high as 200 lb. However, the 60-kg. bag is the accepted statistical unit in most all computations of world production, exports or imports that are expressed in terms of "bags.")

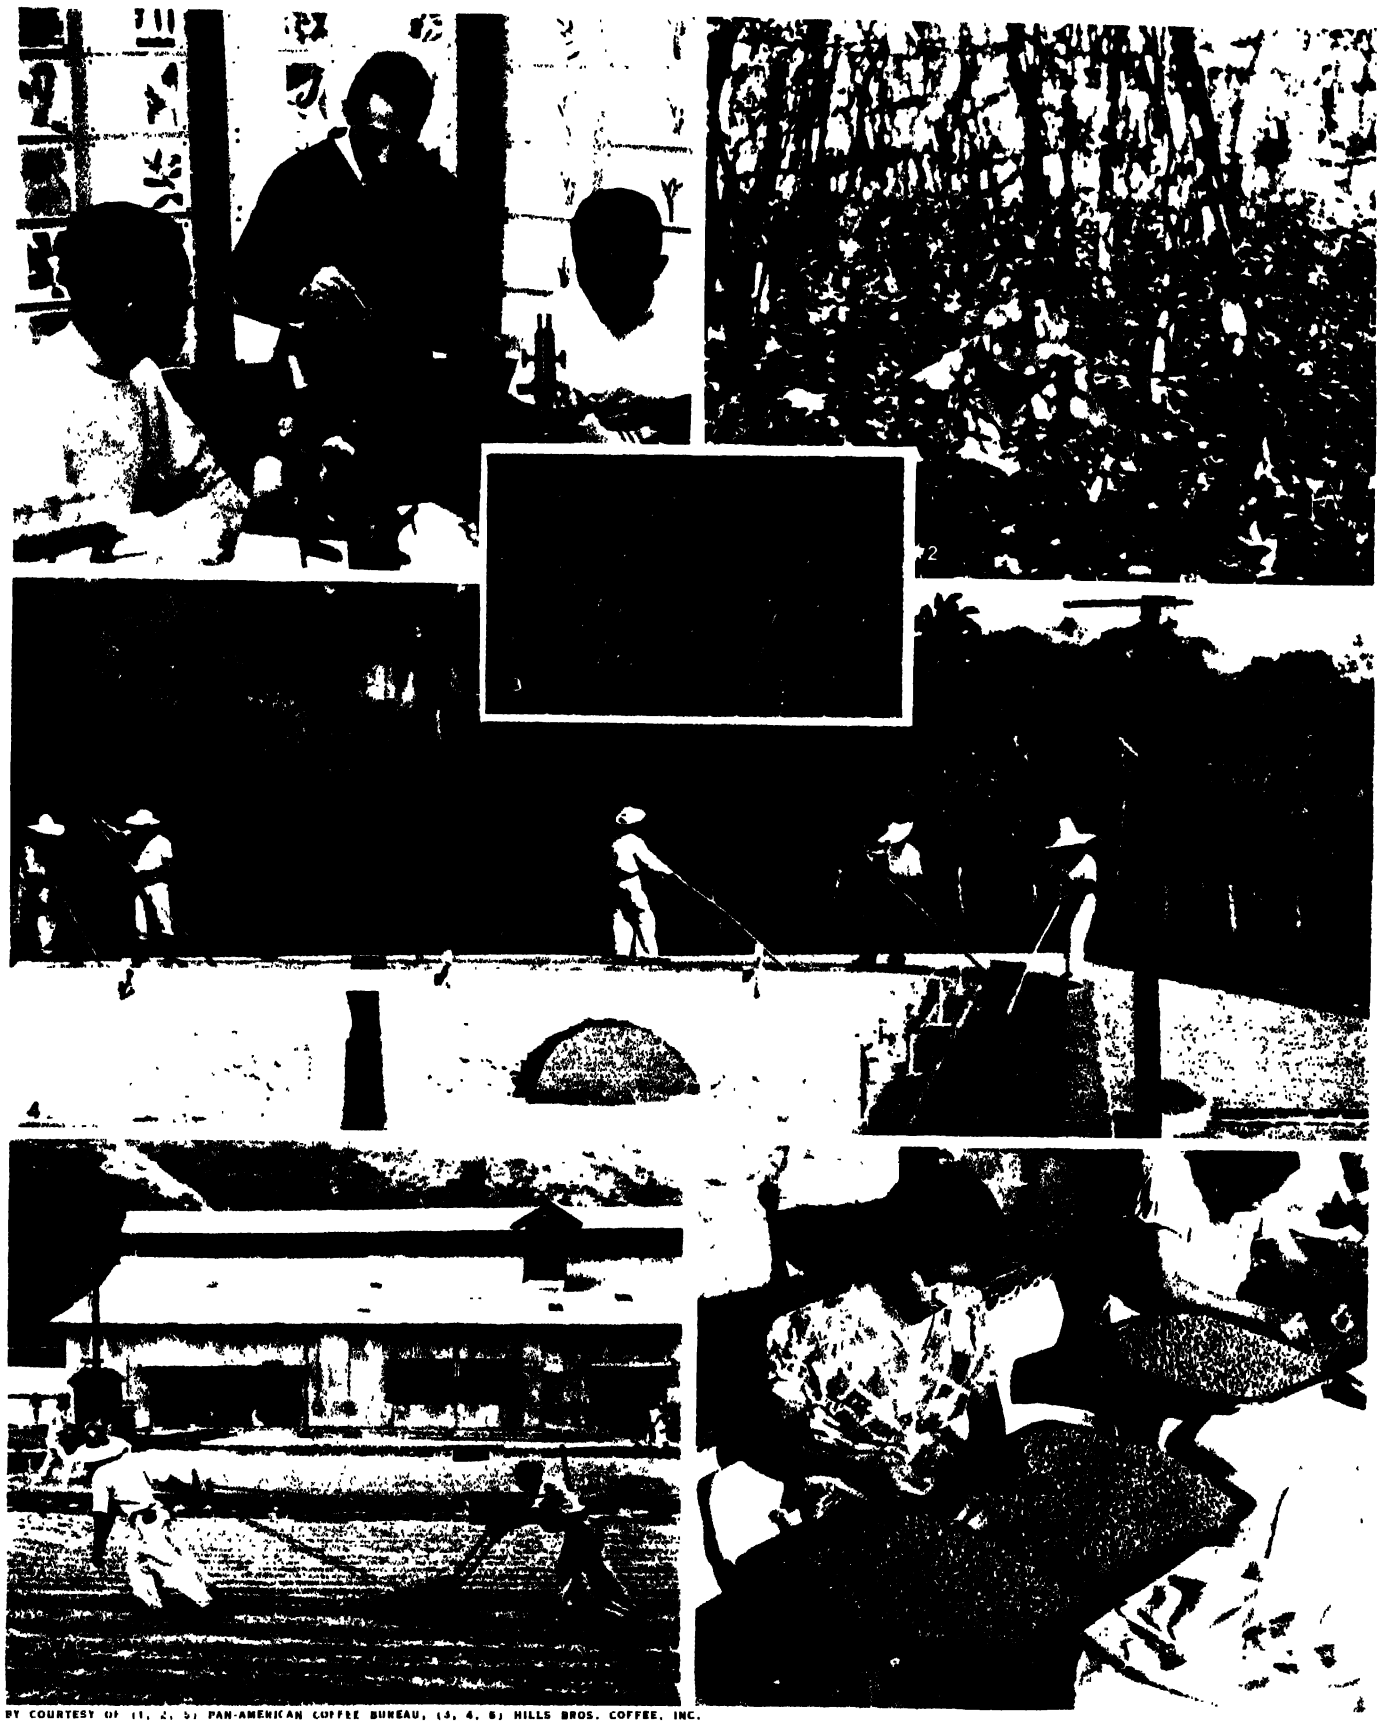
Tasting and Blending.—In European countries, where coffee has been sold to a great extent in the whole bean, purchase used to be largely on the basis of fine appearance of the bean as to size, colour, and other physical characteristics, although in the years subsequent to 1946, when Europe began to again become a customer in the world coffee market (after World War II), this practice became less general. In the U.S., over a long period of years, a more selective manner of purchasing was established; coffees are bought primarily on cup test for taste and quality. Coffee testing is the work of a lifetime. Proficiency cannot be attained in a few months, or even a few years. Most coffee testers start training at an early age and continue study almost without interruption, for they must depend entirely upon taste and smell and devote great attention to the development of those senses. It has been said that the test to which coffee is subjected is one of the "most delicate known to science," since coffee defies all known chemical tests for evaluation of quality. That can be determined only by the senses of taste and smell.

Coffees grown in the various countries differ by types and kind, as well as by grades. In fact, coffees from different plantations in the same producing sections nearly always show a variety of characteristics. In the parlance of the trade, "Brazils" and "milds" are the terms generally used to distinguish between coffees grown in Brazil and those grown in other countries. All those grown in Central and South America (with the exception of Brazil) fall into the "mild" classification.

Broadly speaking, the "mild" coffees are regarded as superior in characteristics to "Brazils," although this is not a strictly true differentiation, for a great deal of the product of Brazil is of finer quality than some of the coffees which come from "mild" producing countries. In general, coffees grown in Africa and Asia fall into the "mild" classification. Further distinctions are made as to "hardness" or "softness," "high-grown," "washed," "unwashed," "naturals," etc., but these are technical distinctions of grading which primarily concern only the grower and the buyer. It is the intricate task of the coffee tester to combine many different lots of coffee to produce a satisfactory blend of one type or another.

Roasting.—Until roasted, coffee has none of the flavour or taste that a layman might recognize as coffee. Roasting gives the brown colour and transforms the natural elements into others which give coffee its splendid aromatic qualities and pleasing taste. Full development of the flavour depends to a great degree on the avoidance of underroasting or overroasting. Skill and experience is required to avoid the slight variations which might yield an undesirable result. Coffee-roasting firms in the United States lead the world in equipment, some having developed mechanical controls of roasting operations which are considered to be foolproof to the extent of eliminating the element of human error in maintaining uniformity of roast. These basic principles have been adapted by equipment manufacturers who specialize in the building of machinery for the coffee trade. Green coffee loses about 16% of its weight in the roasting process. Therefore, it should be remembered in connection with any study of green coffee statistics that it requires approximately 1.19 lb. of green coffee to produce 1 lb. of roasted coffee; thus, 1 lb. of green coffee is equivalent to .84 lb. of roasted coffee.

Grinding.—Coffees packaged in ground form by the manufacturer go through this process immediately after roasting. In most modern roasting plants, this is done by feeding the coffee through steel rollers which first crack it and then cut it to whatever the particular roaster considers the proper degree of fineness. Some coffees are left in the whole bean to be ground in the grocery store at time of purchase by the ultimate user, or in some cases ground in the home.



Ideas with respect to granulation vary to some extent. Some roasters put out their product in several different degrees of grind, each identified as being especially suited for certain types of coffee-brewing devices. Others produce what is referred to as an "all-purpose grind," composed of certain proportions of coarse, medium, and fine particles intended to permit proper extraction of the taste and strength elements in brewing a cup of beverage balanced in aroma, flavour and strength by any method of preparation.

Early in 1948 the national bureau of standards of the United States department of commerce, in co-operation with the National Coffee Association of the U.S.A., issued a Simplified Practice Recommendation stipulating three degrees of fineness for standard grinds for coffee (with reasonable tolerances) identified as regular grind, drip grind and fine grind. Adherence to these standards is not mandatory, but they have been fairly generally followed by roasters in the United States who market their product in more than one grind. Regardless of the type of grind, uniformity of granulation is important and various methods of checking, principally with wire screen sieves and sieve shakers, are used to make sure that the proportions of the various sized grains run uniformly throughout all production.

Packaging.—Generally speaking, roasted coffee is sold in bulk, in paper packages, or in rigid containers that are either vacuum packed or pressure packed. Bulk coffee, distributed through retail outlets in sacks or wooden drums (like the old cracker barrel), is weighed out to the purchaser; this type of marketing had almost entirely disappeared in the United States before the middle of the 20th century. Coffee sold in special types of paper bags or cartons is usually packaged by the manufacturer and distributed over reasonably small geographic areas from central roasting points. Most roasters operating over larger areas (and this is particularly true in the United States) pack coffee by the vacuum process either in metal cans or in glass jars. This is done immediately after roasting and grinding.

Ground coffee begins to lose freshness when exposed to the air because of oxidation of the essential strength and flavour-giving elements. The vacuum-packing process, first applied to the packaging of coffee in 1900 by a firm in San Francisco, Calif., protects the quality of coffee over a long period of time and makes it possible for the manufacturer to preserve the flavour and freshness of coffee ground in his plant immediately after roasting, rather than later at the time of purchase in the store or in the home.

After the can or jar is filled with coffee, the air is withdrawn from the container, which is then hermetically sealed, thereby

PREPARATION OF COFFEE FOR MARKET

1. Preparing samples for testing in miniature coffee roasters
2. Testing coffee by tasting and smelling before making the blend
3. Cross-section of a coffee cherry: A. pulpy skin. B. jelly layer. C. parchment. D. silver skin. E. coffee bean
4. Emptying sacks of coffee into the mixing hopper for blending
5. Coffee-grinding mill
6. Automatically controlled coffee-roasting machine
7. Vacuum-packing coffee

preventing the entrance of air until the container is first opened. The same result is achieved by pressure packing, the main difference in this process being the introduction of an inert gas into the can after the air is withdrawn and before the can is sealed.

By the mid-1950s, approximately two-thirds of all the home-consumed ground coffee in the United States was vacuum packed, mostly in metal cans. During World War II, this type of production was converted to glass jars during shortages of metal containers, but when restrictions were rescinded, consumer preference caused most roasters to revert to cans. In the meantime, however, glass jars had become established as the most generally used container for soluble coffee.

Soluble Coffee.—There are three types of soluble coffee: (1) dried or dehydrated; (2) liquid extract; (3) frozen concentrate. In all instances, the product represents coffee that, in effect, has been brewed into beverage from roasted and ground coffee beans and reduced partially or wholly into solid form. Liquid coffee extract had not, by the mid-1950s, proved very practical, largely because of the factors of deterioration and spoilage over a period. Frozen concentrate likewise had not made any notable progress. Although records of patents on powdered or liquid coffee concentrate or essence date back to the early 19th century (mostly in Europe), such a product did not become a commercial reality until G. Washington, an American chemist residing temporarily in Guatemala City, invented a "refined soluble coffee" in 1906 which was placed on the United States market in 1909.

Prior to World War II, soluble coffee as a factor in the coffee industry (with only a very few brands on the U.S. market) was relatively negligible. Its popularity, however, was considerably enhanced by use as "field rations" under war conditions, and subsequently several companies which had begun to produce such a product for military supply began to market commercial brands of "instant coffee," so-called because of its preparation into beverage simply by the addition of hot water.

Spurred by the force of extensive promotion and the ready consumer acceptance of all types of convenience items in the food field, soluble coffee grew by leaps and bounds from a relatively modest position in 1946 until it was estimated by grocery trade authorities in the mid-1950s that approximately one out of every four or five cups of coffee prepared in the U.S. home was of the soluble type.

In its early period of rapid growth, soluble coffee in dry form (referred to as powdered or granular) was either all coffee or what is known as product type or filled type (coffee with carbohydrates added). With continuing improvement in the quality of soluble coffee, a distinct consumer preference began to be evidenced in favour of all-coffee and by the mid-1950s the product type had practically disappeared from the U.S. market.

The manufacturing of soluble coffee is an intricate process, varying considerably from company to company according to their respective differences in process and equipment development. Generally speaking, however, soluble coffee is produced by first blending, roasting and grinding as in the case of regular ground coffee. Then follow stages of extraction, evaporation and drying (for powdered instant coffee) by one of several methods, the two systems most commonly used being spray drying and drum (or belt) drying in vacuum. Varying percentages of extraction and differences in methods of evaporation and drying produce instant coffees unlike each other in colour, as well as type and fineness of particles, and density. Packaging of the finished product is done by automatic machinery either in glass jars or cans, glass containers being in most common use in the 1950s.

Decaffeinated Coffee.—A process was developed in Germany about 1900 by Ludwig Roselius, a coffee merchant, for the producing of roasted coffee from which a large percentage of the caffeine had been removed. His technique was later improved by manufacturers in the United States, although the processes for accomplishing decaffeination remained more or less secret. In general, it may be said that the result is attained through the use of steam, or by soaking green coffee in a benzene derivative (ether) before roasting. The product is still pure coffee, but lacking some characteristics of the natural bean. In the mid-1950s it was estimated by food marketing authorities that decaffeinated coffee accounted for approximately 1% of all home-consumed ground coffee. At that time it appeared that preference in decaffeinated coffee had noticeably shifted from ground coffee to instant decaffeinated coffee, the volume of which was approaching one-fifteenth of all soluble coffee consumed in homes.

World Production.—The shift of predominance in coffee production, centring originally in Arabia and other sections of the old world, found the Latin American countries of the western hemisphere in the 20th century growing up to nearly 90% of all the coffee produced in the world. However, with the rapidly increasing rate of coffee growing in Africa (particularly after 1945) the western hemisphere's share had dropped during the 4-yr. period ending June 30, 1954, to approximately 83% of the world total. Brazil, the largest of all coffee-growing countries, alone produced 65% of the world total in the 5-yr. period ending June 30, 1934, but only 48% in the 4-yr. period ending June 30, 1954, as a result of steadily declining production in that country and notable increases in Colombia, Mexico and Africa.

Table I shows exportable production by principal countries from 1929 to 1954 and indicates the shifts in output that took place during those years.

TABLE I.—*Exportable Production of Principal Coffee Producing Countries*

*In these years, Cuba consumed all of the coffee grown in that country.

World Exports.—Table II, showing world exports of coffee by countries from 1930 to 1953, offers an interesting comparison with the table of exportable production. It illustrates a phase of the operation of the law of supply and demand which exerts considerable influence on the price of coffee, up and down. Note, for example, the tremendous overproduction in the 10-yr. period 1930 to 1939. This was preponderantly in Brazil, and it was during that period that Brazil was obliged to destroy approximately 68,000,000 bags of coffee, while coffee prices pursued a downward course until they reached their all-time low in 1940.

About a year later, exports began to exceed production and the remaining surpluses accumulated in Brazil started to dwindle, gradually being reduced to approximately 3,000,000 bags at the end of the marketing year 1953–54, an amount which, on the basis of Brazil's annual exports, might be considered as "working inventory."

This turn in the relationship between production and exports in the early 1940s started an upward trend in coffee prices. Arrested during the period of price control in the United States (April 1942 to Oct. 1946), the upward movement resumed and continued with intermittent interruptions until 1951. Then followed a period of comparative stability in the coffee market until 1953. In July of that year, Brazil reported serious frost damage to millions of trees and, spurred on by predictions of smaller supplies

*In these years, Cuba consumed all of the coffee grown in that country.

from that country, the up-trend resumed and coffee prices spiralled to an all-time high in April 1954.

The suddenness and sharpness of the increase in coffee prices during this period caused great concern and met considerable opposition in the United States—the world's largest user of coffee. Investigations were ordered by Pres. Dwight D. Eisenhower and the U.S. senate to determine whether other influences than supply and demand were responsible. Meanwhile, imports into the U.S. had fallen off because of consumer resistance to high prices; world supplies had turned out to be somewhat larger than previously anticipated; and in August of that year (1954) green coffee prices fell off more abruptly than at any time in history, continuing to drop in the months that followed.

World Imports and Consumption.—Prior to 1914, Europe imported more than half the world's supply of coffee and the United States about one-third (with world imports totalling around 17,000,000 bags annually). By 1934, however, as shown in Table III, the United States was taking approximately 50% of the total amount; during the years of World War II the average was almost 80%, dropping back to an average of 63% in 1951 to 1953 as European imports recovered to approximately 80% of their pre-war total.

In per capita consumption, however, the United States lagged

*U.S. range from 15,536 in 1940 to 20,542 in 1945. Low of 12,963 in 1942 was under government control of imports and rationing.

behind Denmark and Sweden up to 1938, after which the United States began to move ahead, reaching a peak in 1946 and declining slightly thereafter (except in 1949) to a level of about 17 lb. of green coffee per capita in 1953. Reports on per capita consumption for any given year are at best "good estimates" because they can be based only on annual imports, without consideration of changes in inventory levels at the beginning and end of the year, and on population figures, which for many of the larger coffee-consuming areas are uncertain. As a matter of interest and "general comparison," however, some 1953 estimates were: Sweden, 15.7 lb.; Denmark, 14.7 lb.; Belgium, 12.7 lb.; Finland, 12.1 lb.; Norway, 11.5 lb.; Switzerland, 9.2 lb.; France, 8.5 lb.; the Netherlands, 6.6 lb. In spite of the early historical preference for coffee in England in the 17th and 18th centuries, the United Kingdom by the 20th century ranked low as a coffee market, although its per capita consumption is estimated to have increased since World War II to 1.4 lb. in 1953.

Pan-American Coffee Bureau.—Described as "an instrumentality of the governments of the member countries," the Pan-American Coffee bureau was organized in Oct. 1936, and began to function in Jan. 1937. By the mid-1950s its membership consisted of the government coffee departments or the officially recognized coffee associations of Brazil, Colombia, Costa Rica, Cuba, the Dominican Republic, Ecuador, El Salvador, Guatemala, Honduras, Mexico and Venezuela.

Financed by its member countries, a major activity of the bureau is a co-operative program of promotion and education designed to increase consumption of coffee in the United States. During the years 1938 to 1941, per capita consumption in the United States increased approximately 20% and, although many factors were involved, the joint effort of the members of this bureau is credited as being the most effective single influence.

Inter-American Coffee Agreement.—After the invasion of Norway and the Netherlands early in World War II (May 1940) almost all of the European coffee market was lost and it became necessary for producers to attempt to sell their entire output to the United States. In the wake of enormous overproduction, there followed a disruption of prices which created a distinct threat to the economic stability of the producing countries. The purpose of the Inter-American Coffee agreement between the governments of the United States and 14 Latin American coffee-producing countries (Nov. 28, 1940) was to make possible the orderly marketing of coffee under those extraordinary conditions. This was done by equitable allocation of the United States coffee market among the participating countries through limitation of exports from those countries to an agreed basic annual quota.

Having accomplished terms of trade equitable for both producers and consumers of coffee during the critical early years of its existence, and the need for export limitation having passed, the agreement expired Sept. 30, 1948. Thereafter, the Special Commission on Coffee was established within the Inter-American Economic and Social council in order that the United States and representatives of producing countries of the western hemisphere might continue to have the opportunity to discuss any problems of mutual concern affecting coffee.

How to Make Coffee.—Making a cup of good coffee is an art in which anyone can become proficient. Yet it requires the same careful attention as is given to the preparation of other articles of food. The Coffee Brewing Institute, Inc., a nonprofit membership corporation formed in 1952 by the Pan-American Coffee Bureau and the National Coffee Association of U.S.A., to encourage, through research and education, the improvement of coffee as a beverage, recommends observance of these few simple rules: (1) Start with a thoroughly clean coffee maker. Rinse with hot water before using. Wash thoroughly after each use. Rinse with hot water and dry. (2) Use fresh coffee. Buy coffee in the size of can or package which will be used within a week after opening. (3) For best results start with freshly drawn cold water. (4) Use the full capacity of the coffee maker. For lesser quantities, it is best to use a smaller coffee maker. Never, in any case, brew less than three-fourths of the coffee maker's capacity. (5) Measure both coffee and water accurately. Stand-

ard recommendation for full-strength beverage is two level tablespoons of coffee to each ½ measuring cup (6 oz.) of water. (6) After finding the exact timing to obtain the results desired with any coffee maker, stick to it in order to get uniform beverage. Consistent timing is important. (7) Coffee should never be boiled. When coffee is boiled, an undesirable flavour change takes place. (8) Serve coffee as soon as possible after brewing. Freshly brewed coffee always tastes best. If necessary to let coffee stand for any length of time after making, hold at serving temperature by placing the utensil in a pan of hot water over very low heat on an asbestos pad. Electrical devices usually have a "warm" unit for maintaining temperature.

Making Soluble (Instant) Coffee.—Soluble coffee can be prepared for individual servings right in the cup, or several cups at a time in any clean utensil, simply by adding the desired amount of boiling water to a measured amount of instant coffee and stirring. It is preferable to pour the water onto the coffee rather than measure the coffee into the water.

Most directions for preparing instant coffee call for "about 1 teaspoon to each cup of water." The exact amount depends on the size of cup, individual strength-preference, and the coffee itself. The degree of concentration is not the same in various soluble coffees, so larger or smaller measurements of one product may be required than of another to produce equivalent strength.

For preparation of iced coffee fill glass containing instant coffee half-full of cold water, stir, and fill with ice. Quantities can be made similarly in a larger utensil.

COFFER, in architecture, a sunk panel in a ceiling or vault; also a casket or chest in which jewels or precious goods are kept, and, if of large dimensions, clothes. The marriage coffers in Italy were often richly carved and gilded and sometimes painted by great artists. (*See* CHEST.)

COFFERDAM, a temporary dam formed to enable foundations to be laid or other construction operations to be undertaken on a site which is underwater. The engineer surrounds the site with an enclosure in such a fashion as to make possible its dewatering.

When the depth of the water is small and the current slight, simple clay dams may be used, but in general cofferdams are somewhat more complicated structures. One type consists of two rows of continuous wooden piles tied together at the top and filled between with clay puddle. Another frequently-used type consists of adjacent cells whose continuous outside walls consist of interlocking vertical sheet steel piling. They are also often filled with packed clay puddle. These cells join one another in such a way as to surround the site of the structure to be erected. The enclosed space may then be pumped dry. A cofferdam must be sufficiently strong to withstand the exterior pressures which arise under these circumstances. (W. E. HD.)

COFFEYVILLE, a city of Montgomery county, in southeastern Kansas, U.S., on the Verdigris river, near the southern boundary of the state. It is on federal highways 166 and 169 and is served by the Missouri Pacific, the Santa Fe and the Missouri-Kansas-Texas. It has two airports. The population was 17,113 in 1950; 17,355 in 1940; and 16,198 in 1930.

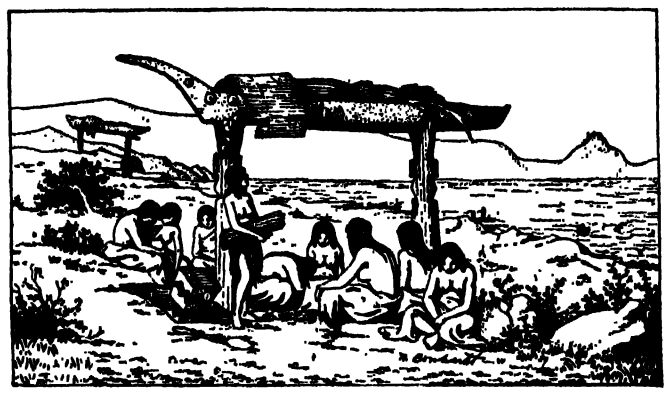
Coffeyville is an industrial, business, agricultural and dairy centre; is in the midcontinent gas and oil field. It has a large and modern co-operative oil refinery, zinc smelter, flour and feed mills, two brick and tile plants, tank car plant, foundries, oil and gas machinery industries and aircraft factories.

Coffeyville was founded in 1869 and incorporated in 1872. It was named after Col. James A. Coffey, who established a trading post there in 1868.

After the railway came through it became a shipping point for cattle from Texas and Indian territory and a trade centre for a wide area. Natural gas was discovered in 1892.

COFFIN, CHARLES CARLETON (1823–1896), U.S. war correspondent and author, is remembered particularly for his popular children's books. He was born at Boscawen, N.H., on July 26, 1823, the son of a farmer. He studied at a village school and an academy and later engaged in farming and surveying. With his brother-in-law, Moses Farmer, he established the first electric fire-alarm system in Boston, Mass., in 1852.

Assistant editor of the *Boston Atlas*, 1856–57, he became a correspondent for the *Boston Journal*, and during the Civil War his dispatches, sent under the pseudonym "Carleton," earned him wide fame. He reported an eyewitness account of the battle of Bull Run and covered many important campaigns of the war.



In 1866 he went to Europe to cover the Prusso-Austrian War, returning the following year by way of India, China, Japan and the Pacific coast. That journey was described in *Our New Way Round the World* (1869), and a later trip to the west was covered in *The Seat of Empire* (1870).

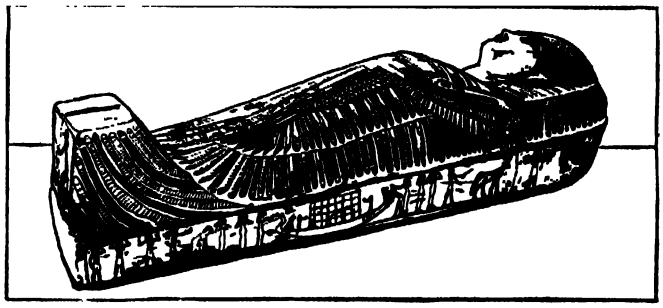
Coffin's books on his war experiences included *My Days and Nights on the Battlefield* (1864) and *Four Years of Fighting* (1866; later published as *The Boys of '61*).

Coffin also published books on the lives of Presidents James Garfield (1880) and Abraham Lincoln (1892) and wrote the novels *Winning His Way* (1866) and *Caleb Krinkle* (1875) and *History of Boscawen and Webster* (1878). U.S. history was the subject of his series entitled *Drum-Beat of the Nation* . . .

His style was vigorous and vivid, and his children's books, such as the popular *The Boys of '76* (1876) and *The Story of Liberty* (1879), were widely read. Coffin, who often lectured, settled in Boston, Mass., and was elected to the state legislature. He died on March 2, 1896.

COFFIN, the receptacle in which a corpse is confined (Lat. *cophinus*, a coffer, chest or basket, but not "coffin" in its present sense). The Greeks and Romans disposed of their dead both by burial and by cremation. Greek coffins varied in shape, being in the form of an urn, or like the modern coffins, or triangular, the body being in a sitting posture. The material used was generally burnt clay, and in some cases this obviously had first been moulded

FROM THE SMITHSONIAN BUREAU OF ETHNOLOGY REPORT



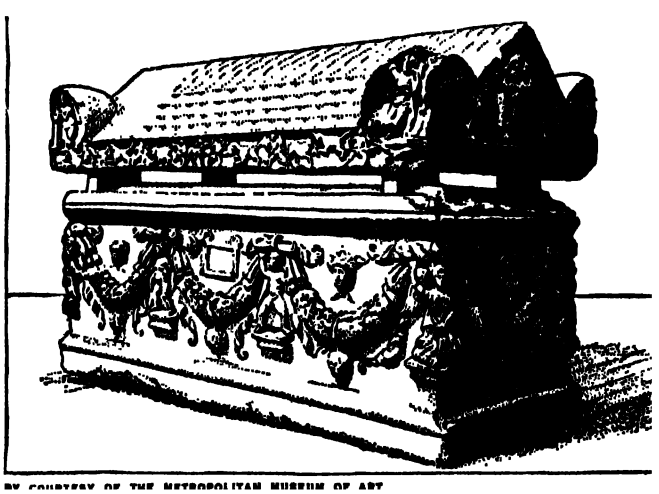
CANOE BURIAL. FORMERLY PRACTICED AMONG AMERICAN INDIAN TRIBES The corpse, wrapped in skins or other covering, was laid in a canoe and placed on a wooden scaffold, where it remained for a certain period while mourners kept watch below. Sometimes the canoe coffin was set afloat on the water, to be carried in the direction of the current

round the body, and so baked. In the Christian era stone coffins came into use. Examples of these have frequently been dug up in England. Those of the Romans who were rich enough had their coffins made of a limestone brought from Assos in Troas, which it was commonly believed "ate the body"; hence arose the name sarcophagus (*q.v.*).

The coffins of the Chaldaeans were generally clay urns with the top left open, resembling immense jars, moulded round the body, as the size of the mouth would not admit of its introduction after the clay was baked. The Egyptian coffins, or sarcophagi, as they have been improperly called, are the largest stone coffins known and are generally highly polished and covered with hieroglyphics, usually a history of the deceased. Mummy chests shaped to the form of the body were also used, being made of hard wood or

papier mâché painted, and bore hieroglyphics. Unhewn flat stones were sometimes used by early European peoples to line the grave. One was placed at the bottom, others stood on their edges to form the sides, and a large slab was put on top, thus forming a rude cist. In England after the Roman invasion these rude cists gave place to the stone coffin which was used until the 16th century.

Primitive wooden coffins were formed of a tree-trunk split down the centre, and hollowed out—a type still in use among peoples in



BY COURTESY OF THE METROPOLITAN MUSEUM OF ART

A MUMMY CHEST COVERED WITH STUCCO, XVII–XVIIITH DYNASTY
This type of coffin, shaped in the form of the body of the deceased, was favoured by less wealthy Egyptians. The example above was excavated at Thebes

the lower culture. The earliest specimen of this type is in the Copenhagen museum, the implements found in it proving that it belonged to the Bronze Age. This type of coffin, more or less modified by planing, was used in mediaeval Britain by those who could not afford stone, while the poor were buried without coffins, wrapped simply in cloth or even covered only with hay and flowers. Towards the end of the 17th century, coffins became usual for all classes.

Among the American Indians some tribes, *e.g.*, the Sacs, Foxes and Sioux, used rough hewn wooden coffins; others, such as the Seris, sometimes enclosed the corpse between the carapace and plastron of a turtle. The Seminoles of Florida used no coffins, while at Santa Barbara, California, canoes containing corpses have been found buried, though they may have been intended for the dead warrior's use in the next world. Rough stone cists, too,

BY COURTESY OF THE METROPOLITAN MUSEUM OF ART

A SCULPTURED ROMAN SARCOPHAGUS FOUND AT TARSUS
In the resemblance of this lid to the roof of a house, is preserved the original idea of the coffin as a dwelling-place for the dead. Since the Roman coffin was usually placed against a wall inside a tomb, the back is generally free of decoration

have been found in Illinois and Kentucky. In their tree and scaffold burial the Indians sometimes used wooden coffins or travois baskets, or the bodies were simply wrapped in blankets. Canoes, mounted on a scaffold, near a river, were used as coffins by some tribes; while others placed the corpse in a canoe or wicker basket and floated it out into the stream or lake. The aborigines of Australia generally used coffins of bark, but some tribes employed baskets of wicker-work.

Lead coffins were used in Europe in the middle ages, shaped like the mummy chests of ancient Egypt. Iron coffins were certainly used in England and Scotland as late as the 17th century. The coffins used in England to-day are generally hexagonal in shape, of elm or oak lined with lead, or with a leaden shell. In America glass is sometimes used for the lids, and the inside is lined with copper or zinc. The coffins of France and Germany and the Continent in general usually have sides and ends parallel. Coffins used in cremation throughout the civilized world are of some light material easily consumed and yielding little ash. Ordinary thin deal and *papier mâché* are the favourite materials. Coffins for what is known as Earth to Earth Burial are made of wicker-work covered with a thin layer of *papier mâché* over cloth.

COG. (1) A broadly built, round-shaped ship, used as a trader and also as a ship of war till the 15th century (M.E. *cogge, cf.* O.Fr. *cogue,* from which "cock-boat" is derived). (2) A tooth in a series of teeth, on the circumference of a wheel, which works with the tooth in a corresponding series on another wheel (*see* MECHANICS). (3) A slang term for a form of cheating at dice.

COGERS' HALL, a London tavern debating society. Instituted in 1755 at the White Bear Inn, Fleet street, and moved about 1850 to Shoe lane; in 1871 it migrated to the Barley Mow Inn, Salisbury square, E.C., and has since moved to the Cannon Inn, Cannon street, E.C. The accepted derivation is from Descartes' *Cogito, ergo sum,* "The Society of Thinkers." The aims of the Cogers were "the promotion of the liberty of the subject and the freedom of the press, the maintenance of loyalty to the laws, the rights and claims of humanity and the practice of public and private virtue." Among its early members Cogers' Hall reckoned John Wilkes, one of its first presidents, and Curran. Later Dickens was a prominent member.

See Peter Rayleigh, *History of Ye Antient Society of Cogers* (1904).

COGHLAN, SIR TIMOTHY AUGUSTUS (1856–1926), Australian civil servant, second son of Thomas Coghlan, an Irish Roman Catholic, was born in Sydney and educated at Sydney Grammar School. He went into Government service in 1873, in the Public Works Department, and in 1884 became assistant engineer of harbours and rivers. In 1885 he was appointed head of the newly-created department of statistics, and was responsible for the preparation of much valuable material, including a full statistical register of trade and commerce in New South Wales. His most important work is the *History of Labour and Industry in Australia* (4 vols. 1918). He also published: *Wealth and Progress of New South Wales* (1887); *Statistical Account of Australia and New Zealand* (1891); *Progress of Australia in the 19th century,* in collaboration with the Hon. T. T. Ewing (1903).

From 1905 to 1915 he held the post of Agent-General for New South Wales, and was knighted in 1914. He was re-appointed from 1916–17, 1920–25, and again on the resignation of Sir Arthur Cocks. With Sir Joseph Cook he represented Australia on the Pacific Cable Board, and he held various public appointments in New South Wales (Chairman of Board of Old Age Pensions, etc.), serving also on several Royal Commissions. He took a great interest in vital statistics, and was in charge of the census in New South Wales in 1891 and 1901. He died on April 30, 1926.

COGHLAN, CHARLES FRANCIS (1841–1899), Irish actor, was born in Paris, and made his first London appearance in 1860. He went to America in 1876, where he remained for the rest of his life, playing first in Augustin Daly's company and then in the Union Square stock company, during the long run of *The Celebrated Case.* He also played with his sister, and in support of Mrs. Langtry and Mrs. Fiske, and in 1898 produced a version of Dumas' *Kean,* called *The Royal Box,* in which he starred during the last years of his life. He died in Galveston (Texas), on Nov. 27, 1899.

His sister, the actress ROSE COGHLAN (1853–1932), went to

America in 1871, was again in England from 1873 to 1877, playing with Barry Sullivan, and then returned to America, where she became prominent as Countess Zicka in *Diplomacy*, and Stephanie in *Forget-me-not*. She was at Wallack's almost continuously until 1888, and subsequently appeared in melodrama in parts like the title-role of the *Sporting Duchess*.

COGNAC, a town of southwestern France, capital of an *arrondissement* in the department of Charente, on the left bank of the river Charente, 23 mi. W.N.W. of Angoulême. Pop. (1946) 17,479. The streets of the old town are very narrow, but the newer parts have open spaces such as the Parc François Ier overlooking the Charente. In 1526 Cognac gave its name to a treaty concluded against Charles V by Francis I, the pope, Venice and Milan. Its possession was contested during the wars of religion, and in 1570 it became one of the Huguenot strongholds. In 1651 it successfully sustained a siege against Louis II, prince of Condé, leader of the Fronde. The 12th century church of St. Leger preserves a fine Romanesque façade and a tower of the 15th century. A castle of the 15th and 16th centuries, once the residence of the counts of Angoulême, and a mediaeval gate stand in the older part of the town. Cognac is the seat of a subprefect and has tribunals of first instance and of commerce, a council of trade arbitrators and a chamber of commerce. Its most important industry is the distillation of the brandy (*q.v.*) to which the town gives its name.

Large quantities of brandy are carried, by way of the river, to the neighbouring port of Tonnay-Charente. The industries subsidiary to the brandy trade, such as the making of cases and bottles, occupy many hands. A considerable trade is maintained in grain and cattle.

COGNE, a village, province of Aosta, Italy, from which town it is 16 mi. due south by road (9 mi. direct). Pop. (1951) 1,860 (commune). It lies at the northern foot of the Gran Paradiso and is a favourite summer resort. Victor Emanuel II formed a shooting reserve here for wild goat and chamois. The important iron mines belonging to the Ansaldo company lie east of the village.

COGNITION means "knowing," in the widest sense of the term. In psychology it is used to denote one of the three ultimate functions or processes of consciousness, the others being feeling and conation (or willing). Cognition includes every mental process that can be described as an experience of knowing as distinguished from an experience of feeling or of willing; it includes, in short, all process of consciousness by which knowledge is built up. In its most familiar and fully developed form it is known as judgment, in which a certain object (known logically and grammatically as a "subject") is discriminated from other objects and characterized by some concept or concepts. Although cognition is readily distinguishable from feeling and conation, yet in the actual flow of mental life the three types of experience are always found together, not separate, but one of them is usually predominant in one total experience, another in another, and this fact facilitates their mutual discrimination. Psychology, as a descriptive science, is not concerned with the epistemological question, how external objects can be revealed in subjective experiences; it simply takes at their face value these cognitive experiences in which objects appear to be known somehow, and leaves the critical problems to epistemology and logic.

See PSYCHOLOGY, and KNOWLEDGE, THEORY OF, and authorities there quoted.

COGNIZANCE, knowledge, notice, especially judicial notice, the right of trying or considering a case judicially, the exercise of jurisdiction by a court of law. In heraldry a "cognizance" is an emblem, badge or device used as a distinguishing mark by the body of retainers of a royal or noble house.

COHAN, GEORGE MICHAEL (1878–1942), American actor, author and producer, was born in Providence, R.I., July 4, 1878. His parents were of the theatrical profession, and at an early age he appeared with them in juvenile parts, subsequently taking comedy roles in vaudeville and on the legitimate stage. Also at an early age he began writing plays and popular songs. A description of his early experiments and the stage career of the "Four Cohans" is in his autobiography, *Twenty Years on Broadway and the Years It Took to Get There* (1925).

Among his productions may be mentioned *The Governor's Son* (1901); *Forty-five Minutes from Broadway* (1905); *The Talk of New York* (1907); *Get-Rich-Quick Wallingford* (1910); *Broadway Jones* (1912); *Seven Keys to Baldpate* (1913); *The Tavern* (1920); *The Song and Dance Man* (1923); *American Born* (1925). Among his best-known appearances were in *Ah Wilderness!* (1933) and *I'd Rather Be Right* (1937). His career was the subject of a motion picture, *Yankee Doodle Dandy* (1942). He was the composer of numerous songs, including the famous "Over There" of World War I; for writing the latter he received a Congressional medal. Cohan died in New York city Nov. 5, 1942.

See Ward Morehouse, *George M. Cohan, Prince of the American Theater* (Philadelphia, 1943).

COHEN (Hebrew for "priest"), a Jewish family name, implying descent from Aaron and the Hebrew priests (*Cohanim*). Many families claiming such descent are, however, not named Cohen. Other forms of the name are Cohn, Cowen, Kahn, etc.

COHEN, ERNST JULIUS (1869–1944), Dutch chemist, was born at Amsterdam on March 7, 1869. He studied chemistry under Svante Arrhenius at Stockholm, Swed., Henri Moissan at Paris, and Jacobus van't Hoff at Amsterdam; he became assistant to the latter in the university chemical laboratories at Amsterdam in 1893, and in 1902 professor of physical chemistry at the University of Utrecht. He headed the Van't Hoff laboratory founded there in 1904. Cohen's most important work was on the allotropy of metals, particularly tin. He published a large number of works on piezochemistry and electrochemical thermodynamics, particularly in relation to the study of standard galvanic cells; he also wrote widely on the history of science. During World War II he was arrested by the Germans because of his Jewish descent and was gassed at the concentration camp of Auschwitz, Ger., on or about March 15, 1944. Cohen's writings include: *Physical Chemistry for Biologists, Inorganic Chemistry for Medical Students* (1907); *Jacobus Henricus van't Hoff, Sein Leben und Werken* (Leipzig, 1912); *Piezochemie kondensierte Systeme* (Leipzig, 1919); *Physico-Chemical Metamorphosis and some Problems in Piezochemistry* (1928).

COHERER, a device by means of which a feeble oscillating electric current may be detected by a galvanometer or telephone, the essential characteristics being that the current through the coherer is concentrated at a point and that the resistance of the material has a negative temperature coefficient so that the coherer is self-restoring. A simple form of coherer consists of an oxidized iron plate against which rests the point of a steel needle. (*See* GALVANOMETER; TELEPHONE.)

COHESION: *see* SOLID STATE, THEORY OF.

COHN, FERDINAND JULIUS (1828–1898), German botanist, was born on the 24th of January 1828 at Breslau. He was educated at Breslau and Berlin, and in 1859 became extraordinary, and in 1871 ordinary, professor of botany at Breslau university. He was contemporary with N. Pringsheim, and worked with H. R. Goeppert, C. G. Nees von Esenbeck, C. G. Ehrenberg and Johannes Müller. He made remarkable advances in the establishment of an improved cell-theory, discovered the cilia in, and analyzed the movements of, zoospores, and pointed out that the protoplasm of the plant-cell and the sarcode of the zoologists were one and the same physical vehicle of life. Although these early researches were especially on the Algae, in which group he instituted marked reforms of the rigid system due to F. T. Kützing, Cohn studied such varied subjects as *Aldorovanda*, torsion in trees, the nature of waterspouts, the effects of lightning, physiology of seeds, the proteid crystals in the potato, which he discovered, formation of travertin, the rotatoria and luminous worms.

It is, however, in the introduction of the strict biological and philosophical analysis of the life-histories of the lower and most minute forms of life that Cohn's greatest achievements consist, for he applied to these organisms the principle that we can only know the phases of growth of microscopic plants by watching every stage of development under the microscope, just as we

learn how different are the youthful and adult appearances of an oak or a fern by direct observation. His account of the life-histories of *Protococcus* (1850), *Stephanosphaera* (1852), *Volvox* (1856 and 1875), *Hydrodictyon* (1861), and *Spaeroplea* (1855–1857) among the Algae have never been put aside. The first is a model of what a study in development should be; the last shares with G. Thuret's studies on *Fucus* and Pringsheim's on *Vaucheria* the merit of establishing the existence of a sexual process in Algae. Among the Fungi Cohn contributed important researches on *Pilobolus* (1851), *Empusa* (1855), *Tarichium* (1869), as well as valuable work on the nature of parasitism of Algae and Fungi.

Cohn may be said to have founded the science of bacteriology. He seems to have been always attracted particularly by curious problems of fermentation and coloration due to the most minute forms of life, as evinced by his papers on *Monas prodigiosa* (1850) and "Über blutähnliche Färbungen" (1850), on infusoria (1851 and 1852), on organisms in drinking-water (1853), "Die Wunder des Blutes" (1854), and had already published several works on insect epidemics (1869–1870) and on plant diseases, when his first specially bacteriological memoir (*Crenothrix*) appeared in the journal, *Beiträge zur Biologie*, which he then started (1870–71), and which has since become so renowned. Investigations on other branches of bacteriology soon followed, among which "Organismen der Pockenlymphe" (1872) and "Untersuchungen über Bacterien" (1872–1875) are most important, and laid the foundations of the science. Cohn brought out and helped R. Koch in publishing his celebrated paper on *Anthrax* (1876), the first clearly worked out case of a bacterial disease.

Among his most striking discoveries may be mentioned the nature of Zoogloea, the formation and germination of true spores —which he observed for the first time, and which he himself discovered in *Bacillus subtilis*—and their resistance to high temperatures, and the bearing of this on the fallacious experiments supposed to support abiogenesis; as well as works on the bacteria of air and water, the significance of the bright sulphur granules in sulphur bacteria, and of the iron oxide deposited in the walls of *Crenothrix*. His discoveries in these and in other departments attest his acute observation and reasoning powers. Cohn had clear perceptions of the important bearings of Mycology and Bacteriology in infective diseases, as shown by his studies in insect-killing fungi, microscopic analysis of water, etc. He was a foreign member of the Royal Society and of the Linnean Society, and received the gold medal of the latter in 1895. He died at Breslau on June 25, 1898.

Lists of his papers will be found in the *Catalogue of Scientific Papers of the Royal Society*, and in *Ber. d. d. bot. Gesellsch.*, vol. xvii. p. 196 (1899); *see* also P. Cohn, *Ferdinand Cohn*, with Life by F. Rosen.

COHN, GUSTAV (1840–1918), German economist, born on Dec. 12, 1840, at Marienwerder, West Prussia, was educated at Berlin and Jena and became professor of political science first at Zurich (1875), and then at Göttingen (1884). He died at Göttingen on Sept. 20, 1918. His principal works are:

Untersuchungen über die englische Eisenbahnpolitik (Leipzig, 1874–75); *System der Nationalökonomie* (Stuttgart, 1885); *Finanzwissenschaft* (1889); *Nationalökonomische Studien* (1886), and *Zur Geschichte und Politik des Verkehrswesens* (1900).

COHNHEIM, JULIUS (1839–1884), German pathologist, was born at Demmin (Pomerania) on July 20, 1839, and died on Aug. 15, 1884, at Leipzig. After serving as an army surgeon in 1864–65 he became an assistant in the Pathological institute in Berlin and was the most distinguished of Rudolf Virchow's pupils. He was subsequently professor of pathology at Kiel (1868), Breslau (1872) and Leipzig (1878), where he was also director of the Pathological institute. Paul Ehrlich was among his pupils at Breslau. His first important dissertation on inflammation of serous membranes appeared in 1861, and was followed by other important papers on that subject from 1869 to 1873. On this question his teaching was opposed to that of Virchow. He showed that inflammation is caused by the passage of white corpuscles through the walls of the capillaries and that pus is formed largely of these corpuscles in a disintegrated state. Cohnheim made many useful innovations in the method of microscopical work. His most important book is his *Vorlesungen über allgemeine Pathologie* (Berlin, 1878).

See Berlin klin. Wchnschr., vol. 21, p. 564 (1884).

COHOES, a manufacturing city of Albany county, N.Y., U.S., 9 mi. N. of Albany, on the Hudson river at the mouth of the Mohawk. It is served by the Delaware and Hudson and the New York Central railways, and by the state barge canal. The population of Cohoes in 1950 was 21,235, and was 21,955 in 1940 by the federal census. Water power from the falls of the Mohawk (75 ft. high and 900 ft. across) is supplemented by a hydroelectric plant developing 54,000 h.p.

Chief among the many manufactures are cotton and woollen knit goods, cotton fabrics, collars and shirts, machinery, bond-paper and tractors. Cohoes was part of the manorial grant made to Killian van Rensselaer, and probably it was settled soon after 1629. It was incorporated as a village in 1848 and as a city in 1869. The Van Schaick manor house was the headquarters of Gen. Philip Schuyler during part of the Revolutionary War. The old colonial military road from Albany to Ft. Edward and Lake George runs through the city.

COHORT (Lat. *cohors*), originally a place enclosed; in the Roman army, the name of a unit of infantry. The troops of the first grade, the legions, were divided into cohorts, of which there were ten in each legion: the cohort thus contained 600 men. Among the troops of the second grade (the *auxilia*) the cohorts were independent foot regiments 500 or 1,000 strong, corresponding to the *alae*, which were similar regiments of cavalry; they were generally posted on the frontiers of the empire in small forts of four to eight acres, each holding one cohort or *ala*. The special troops of Rome itself, the Praetorian Guard, the *Urbanae Cohortes*, and the *Vigiles* (fire brigade), were divided into cohorts (*see* further ROMAN ARMY). The phrase *cohors praetoria* or *cohors amicorum* was sometimes used, especially during the Roman republic, to denote the suite of the governor of a province; hence developed the Praetorian cohorts which formed the emperor's bodyguard.

In biology, "cohort" is a term for a group of allied orders or families of plants or animals.

See J. E. Sandys, *Companion to Latin Studies* (1921), sections 380, 463, 714 *et seq.*, 723–4, 728, 730, 773, 1089.

COIF, a close-fitting covering for the head. Originally it was the name given to a head-covering worn in the middle ages, tied like a night-cap under the chin, and worn out of doors by both sexes; this was later worn by men as a kind of night-cap or skull-cap. The coif was also a close-fitting cap of white lawn or silk, worn by English serjeants-at-law as a distinguishing mark of their profession (*see* SERJEANTS-AT-LAW).

COIMBATORE, city and district, British India, in the Madras presidency. The city is situated on the left bank of the Noyil river, 305 mi. from Madras by the South Indian railway. In 1941 it had a population of 130,348. The city stands 1,437 ft. above sea level, is healthy, and is rendered additionally attractive to European residents by its picturesque position on the slopes of the Nilgiri hills. The famous temple of Perur lies 3 mi. E. of Coimbatore. Coimbatore is an important industrial centre, carrying on cotton weaving and spinning, tanning and the manufacture of coffee, sugar, manure and saltpetre. It has two second-grade colleges, a college of agriculture, training and industrial schools, and a school of forestry.

THE DISTRICT OF COIMBATORE has an area of 7,121 sq.mi. It is a flat, open country, hemmed in by mountains on the north, west and south, but opening eastwards on to the great plain of the Carnatic; the average height of the plain above sea level is about 900 ft. The principal mountains are the Anamalai hills, in the south of the district, rising at places to a height of between 8,000 and 9,000 ft. In the west the Palghat and Vallagiri hills form a connecting link between the Anamalai range and the Nilgiris, with the exception of a remarkable gap known as the Palghat pass. This gap, which completely intersects the Ghats, is about 20 mi. wide. In the north the Cauvery chain extends

eastward from the Nilgiris, and rises in places to 4,000 ft. The principal rivers are the Cauvery, Bhavani, Noyil and Amravati. There are numerous canals, wells and tanks for irrigation. Coimbatore district was acquired by the British in 1799 at the close of the war which ended with the death of Tipu. In 1941 the population was 2,809,648.

The principal crops are millet, rice, other food grains, pulse, oilseeds, cotton and tobacco; and raw silk is produced. Forests, yielding valuable timber, cover a large area. There are cotton mills and factories for pressing cotton, preparing coffee, making soap and dyeing.

The southwest line of the Madras railway runs through the district and the South Indian railway (of metre gauge) joins this at Erode.

COIMBRA, Portuguese city on the north bank of the Mondego river, 115 mi. N.N.E. of Lisbon, on the Lisbon-Oporto railway. Pop. (1950) 42,640. Coimbra is the seat of the oldest of the three Portuguese universities. It was originally established at Lisbon in 1290, was transferred to Coimbra in 1308, was again removed to Lisbon and was finally fixed at Coimbra in 1537. The library contains about 500,000 volumes and the museums and laboratories are on an extensive scale.

The city, picturesquely situated on a hill above the river, is the seat of a bishop, suffragan to the archbishop of Braga; its new cathedral, founded in 1598, is of little interest, but the old one is a fine specimen of 12th-century Romanesque and retains portions of the mosque which it replaced. The principal churches are Santa Cruz, rebuilt in the 16th century on a much older foundation, and San Salvador, founded in 1179.

On the banks of the Mondego stand the ruins of the once splendid monastery of Santa Clara, established in 1286, and the church, built by the monks in the 17th century, which contains the 14th-century crystal and silver tomb of St. Isabel, queen of Portugal. There, too, is the celebrated Quinta das Lagrimas, where Inez de Castro (*q.v.*) is believed to have been murdered in 1355.

A Latin inscription of the 4th century identifies Coimbra with the ancient Aeminium, while Condeixa, 8 mi. S.S.W., represents the ancient Conimbriga or Conimbrica. Aeminium was for more than a century a Moorish stronghold, but in 878 it was recaptured by Alphonso III and peopled by Galicians from the north. The bishop of Conimbriga, who was established there, was forced to leave as a result of the continuous raids by the Moors in the surrounding country. When he later returned he kept his old name of Conimbriga and Aeminium became known as Coimbra. In 1064 it was captured by Ferdinand I of Castile and the first Christian governor was Count Sisnando, a Moor, who reorganized the town. For more than a century it was the centre from which the reconquest of Portugal from the Moors was carried on. No fewer than six kings—Sancho I and II, Alphonso II and III, Pedro and Ferdinand—were born within its walls. It was also the birthplace of the poet Francisco Sá de Miranda (1485?–1558), and, according to one tradition, of the more famous Luis de Camoens (1524–80), who was a student at the university between 1537 and 1545. In 1755 Coimbra suffered considerably from the earthquake and in 1810 it was sacked by the French. In 1834 Dom Miguel made the city his headquarters; and in 1846 it was the scene of a Miguelist insurrection.

The chief industries are wine, biscuits, pottery and paper. Oil is found, and maize, rice and fruits are grown in the district.

COÍN, a town of southern Spain, in the province of Málaga, 18 mi. W.S.W. of Málaga by rail. Pop. (1950) 20,090 (mun.). Coín, on the north slope of the Sierra de Mijas, is the centre of a rich agricultural district. It exports large quantities of oranges, lemons, grapes and raisins, and marble from neighbouring quarries.

COIN. This is properly the term for a wedge-shaped die used for stamping money, and so transferred to the money so stamped; hence a piece of money. The form "quoin" is used for the external angle of a building (*see* QUOIN), and "coign," also a projecting angle, survives in the Shakespearean phrase "a coign of vantage."

The older forms of the word are *coyne, quoin* and *coign,* all derived from the Lat. *cuneus,* a wedge, through the O.F. *coing* and *cuigne.*

For a discussion of coins and coinage, *see* MINT and NUMISMATICS.

COINAGE OFFENSES: *see* COUNTERFEIT MONEY.

COIR, the outer covering of the husk of the coconut; an exceedingly strong fibrous material which has many uses in industry, notably in the manufacture of coarse mats and brushes. The name is derived from the Malay *Kāyar,* cord, *Kāyaru,* to be twisted.

Very large quantities of coir are exported from the Pacific, and there is a considerable market in England, the imports and reexports reaching big figures.

COIRE: *see* CHUR.

COISLIN, a French family of Brittany, originally named Du Cambout, which came into prominence in the 16th century when it inherited the lordship of Coislin (in the modern *département* of Loire-Inférieure) and, further, in the 17th, largely because of its connection with the cardinal de Richelieu. Several of its members held high rank in the army. In the church, Pierre (1636–1706), second son of the marquis de Coislin, Pierre César du Cambout, and of Marie, daughter of the chancellor Pierre Séguier, was bishop of Orléans, a cardinal and grand almoner of France; he treated the Huguenots with great tolerance when the Edict of Nantes was revoked. His nephew Henri Charles (1664–1732), bishop of Metz, premier royal almoner and a member of the Académie Française, bequeathed the chancellor Séguier's library to the abbey of St. Germain-des-Prés, whence it was later transferred in part to the Bibliothèque Nationale.

COITIER, JACQUES (d. 1505), French physician and politician, was born in Poligny in the modern *département* of Jura.

He was attached to the royal court in Paris and became the personal physician of King Louis XI. As such, he exercised a great influence over the king until the latter's death in 1483. He was rewarded with various lucrative offices and lands and became, in 1482, president of the *chambre des comptes* and bailiff of the palace.

Although his political influence waned somewhat after his patron's death, Coitier retained his rank and offices under Charles VIII and Louis XII, with the exception of the presidency of the *chambre des comptes.*

COKE, SIR EDWARD (1552–1634), English judge, was born at Mileham in Norfolk on Feb. 1, 1552. He was educated at Norwich grammar school and Trinity college, Cambridge, and in 1572 entered the Inner Temple. He was called to the bar in 1578, and the next year was chosen reader of Lyon's Inn, a responsible position usually held by counsel of ten years' standing. His early cases included the Cromwell libel case (4 Rep. 13) and *Shelley's Case* (1 Rep. 94), and his reputation became great. In 1582 he married Bridget Paston, who brought him a fortune. In 1589 he became M.P. for Aldeburgh, and in 1592 solicitor general and recorder of London. In 1593 he was chosen as speaker of the house of commons, showing considerable skill in carrying out Elizabeth's policy of curbing the commons' passion for discussing ecclesiastical matters.

In 1593 he first crossed Francis Bacon's course. The attorney generalship fell vacant, and Bacon, supported by Essex, became Coke's rival for the post. Coke got it in 1594 and then kept Bacon out of the solicitorship as well, or so Bacon thought. Coke's wife died in 1598 and four months later he married Lady Elizabeth Hatton, Bacon again being his unsuccessful rival.

As attorney general, Coke started a series of state prosecutions for libel. The theory he advocated was that all comment on the doings of authority was unjustified; the remedy of those aggrieved was to be sought in the courts or in parliament. He also had the conduct of several of the great trials of the day. In 1601 he prosecuted Essex and Southampton, in 1603 Raleigh, and in 1605 the Gunpowder plot conspirators. (*See* Cobbett, *State Trials,* vol. ii.)

In 1606 Coke was made chief justice of the common pleas, and there began at once that series of conflicts which eventually broke his career. At the time of his appointment Archbishop Richard Bancroft had already started his attempt to shake off the control which the common law courts exercised over the ecclesiastical

courts by prohibition, and James, as ever, was ready to support any cause that looked likely to break the supremacy of the common law. This matter came to a head in 1607, when Bancroft renewed his protests and took up the position that the king, as fountain of justice, could remove any cases he pleased from his judges and try them himself. Coke refuted him, in spite of some precedents under the early kings that must have been difficult to get round. But the disputes with the ecclesiastical courts went on. In 1610 Coke gave his celebrated opinion before the council that the king's proclamation cannot change the law, and in 1611 he had a brush with the court of high commission, with the result that the next year he was put on the commission himself; Coke evaded this attempt to muzzle him by finding legal flaws in the commission's appointment. In 1613 Bacon, with an eye to his own advancement and to get Coke into a position where he would be less troublesome, had him "promoted" to be chief justice of the king's bench, an office of higher dignity and less salary. Coke was made a privy councillor, and was the first to be called lord chief justice of England, which was remembered against him afterward. Here his predominance was still as great; and he had to protest, in *Peacham's Case*, against the practice of consulting the judges individually and separately, which James, abetted by Bacon, was more or less driven to follow because when the whole bench was consulted together the rest of the judges merely echoed Coke. In 1615, still an implacable and bigoted adherent of the common law, he tried his strength too high. The court of king's bench started a dispute with the chancery over the right of the chancellor to interfere where a common law court had given a decision, and Coke was believed to be at the bottom of the attempt to make some who had been suitors in a case of this sort liable to the penalties of a praemunire, an attempt which failed. The disputes continued, embittered by Coke's personal dislike for Sir Thomas Egerton, the chancellor. Meanwhile Coke had further endangered his position by throwing out dark hints from the bench in his conduct of the Overbury trials ("God knows what became of that sweet babe, prince Henry, but I know somewhat"). Finally he came into collision with James once more over the king's right to allow commendams (holding of livings in plurality). Coke and the other judges ignored a royal injunction that they should take no action upon a case involving this right until the king's pleasure was known. They were called before the king and council and ordered to obey the injunction. The other judges submitted, but Coke merely said that he would do what an honest and just judge ought to do.

In June 1616 the privy council, with Bacon at the back of it, formulated three charges against him. One was a trumpery matter, never proved, about a bond that had passed through his hands. The other two were charges of interference with the court of chancery and of disrespect to the king in the matter of commendams. He was also ordered to revise the "errors" in his reports. Bacon, then attorney general, made himself very unpopular by engaging Coke on this last issue. Coke remained impenitent and was dismissed. Thereupon, presumably in search of a friend in high places, he offered his daughter in marriage to Sir John Villiers, brother of the duke of Buckingham. His wife, supported by Bacon, objected and hid the child, who was then only 14. Coke found her and married her, strongly against her will, to Villiers. She ran away from him soon afterward. However, Coke got back into the privy council by 1617, and sat in the Star Chamber. In 1620 he entered parliament as member for Liskeard, in theory as a supporter of the king. But for the rest of his career he was a leading member of the popular party. He opposed the Spanish marriage proposals, took a part in drawing up the charges against Bacon and spoke in the liberties of parliament debate, spending nine months in prison as a result. But nothing was found that could incriminate him.

In 1628 it was his Bill of Liberties that ultimately took the form of the Petition of Right. At his last notable appearance he saved the awkward situation caused by the speaker's suppressing Sir John Eliot's attack on the duke of Buckingham, who was, however, not mentioned by name. The house was at a loss and in turmoil. Coke rose and, having named the duke first, went on to say what the house thought of him; whereupon "as when one good hound recovers the scent the rest come in with a full cry so they . . . laid the blame where they thought the fault was." At the end of the session he retired, and died at Stoke Poges on Sept. 3, 1634. His papers were instantly seized and some, including his will, were never recovered.

Barrister, judge and reporter of the first rank, Coke is the greatest common lawyer of all time. He was inclined to be overbearing and impatient both at the bar and on the bench, he was undoubtedly rather narrow and he was not always logical. But his knowledge of the law, in days when it was far more difficult to come by than it is now, was unequalled, and to him more than anyone is owed the reduction of the chaos of the old authorities to the comparatively orderly state of the law as he left it. As a judge he is noted for his wholehearted adherence to the common law. He upheld it against the church, the admiralty and, most dangerous of all, the royal prerogative with success. He tried to uphold it against the chancery, but that was too strong for him. While he was issuing his *Reports* no others came out. They are not so much reports in the modern sense as compendia of the law bearing on a particular case, with comments on points raised or general remarks. The best estimate of his importance as a legal authority is that of C. J. Best, "The fact is that Lord Coke had no authority for what he states, but I am afraid we should get rid of a great deal of what is considered law in Westminster Hall if what Lord Coke says without authority is not law. He was one of the most eminent lawyers that ever presided as a judge in any court of Justice. . . ." Among his other publications are four volumes of *Institutes* (1628 ff.), of which volume i is known as *Coke Upon Littleton*.

As a man, he evokes admiration more readily than sympathy. More learned a lawyer than Bacon but without his philosophical genius, a just judge but a savage prosecutor, obstinate in his opposition to illegal exercise of authority but quite incapable of distinguishing between the prerogative, which wanted to override the law in the interests of absolutism, and the chancery, which sought to counteract its rigidity in the cause of justice, he could cringe before the king even in the act of defying the crown.

See Sir William Holdsworth, *A History of English Law*, vol. v, 2nd ed. (London, 1937); S. R. Gardiner, *History of England 1603–42*, 10 vol. (London, 1883–84). There is no adequate biography.

COKE, SIR JOHN (1563–1644), English politician, was born on March 5, 1563, and was educated at Trinity college, Cambridge. After leaving the university he entered public life as a servant of William Cecil, Lord Burghley, afterward becoming deputy treasurer and then a commissioner of the navy. He became M.P. for Warwick in 1621 and was knighted in 1624, afterward representing the University of Cambridge. In the parliament of 1625 Coke acted as secretary of state; in this and later parliaments he introduced the royal requests for money and defended the foreign policy of Charles I and Buckingham, and afterward the actions of the king. His actual appointment as secretary dates from Sept. 1625. Disliked by the leaders of the popular party, his speeches in the house of commons did not improve the king's position, but when Charles ruled without a parliament he found Coke's industry very useful to him. The secretary retained his post until 1639, when a scapegoat was required to expiate the humiliating treaty of Berwick with the Scots, and Coke was dismissed. He died at Tottenham on Sept. 8, 1644. Coke's son, Sir John Coke, sided with the parliament in its struggle with the king, and it is possible that in later life Coke's own sympathies were with this party, although in his earlier years he had been a defender of absolute monarchy.

COKE, THOMAS (1747–1814), English divine, the first Methodist bishop, was born at Brecon, where his father was a well-to-do apothecary. He was educated at Jesus college, Oxford, taking the degree of M.A. in 1770 and that of D.C.L. in 1775. From 1772 to 1776 he was curate at South Petherton in Somerset, whence his rector dismissed him for adopting the open-air and cottage services introduced by John Wesley, with whom he had become acquainted. After serving on the London Wesleyan circuit he was in 1782 appointed president of the conference in Ireland, a position which he frequently held, in the

intervals of his many voyages to America. He first visited that country in 1784, going to Baltimore as "superintendent" of the Methodist societies in the new world and, in 1787 the American conference changed his title to "bishop," a nomenclature which he tried in vain to introduce into the English conference, of which he was president in 1797 and 1805. Failing this, he asked Lord Liverpool to make him a bishop in India, and he was voyaging to Ceylon when he died on May 3, 1814. Coke had always been a missionary enthusiast, and was the pioneer of such enterprise in his connection. He was an ardent opponent of slavery, and endeavoured also to heal the breach between the Methodist and Anglican communions. He published a *History of the West Indies* (1808–11), several volumes of sermons and, with Henry Moore, a *Life of Wesley* (1792).

COKE, COKING AND HIGH-TEMPERATURE CARBONIZATION. Coke is the solid residue which remains when coal is heated to a high temperature out of contact with air until practically all the volatile matter has been driven off. It consists principally of carbon, together with minor proportions of hydrogen, nitrogen, sulphur and oxygen (which constitute the so-called fixed carbon), plus the mineral matter present in the original coal, which has suffered alteration during the coking process. Commercial cokes always contain water, the amount of which depends on the treatment to which the coke has been subjected after manufacture.

The properties of a coke depend on the type of coal from which it is made and the process employed in its manufacture. Thus, metallurgical coke produced in coke ovens is hard, compact, has a gray steely lustre and is difficult to ignite; it is unsuitable for use in open fireplaces. Gas coke, if made in horizontal retorts, is less strong, has a more open texture and a gray colour and is difficult to ignite and burn in an ordinary fireplace. Gas coke made in continuous vertical retorts through which steam is passed is black in colour, porous, weaker mechanically than oven or horizontal-retort coke; it is more easily ignited and can be burned successfully in properly designed open grates.

The Nature of Coke.—Coke is essentially a partially graphitized form of carbon; its true specific gravity is about 1.85 to 1.9, or about midway between the specific gravities of coal and graphite. Because of its high porosity, however, coke has a considerably lower bulk density than coal; thus for equal weights of the two fuels, coke requires about 40% more storage space. It is the combination of high graphitization and porosity that gives coke its chief value in the smelting of iron, which requires a fuel that will burn rapidly in the lower regions of the furnace, giving a high temperature for the melting of the iron and slag, mechanical strength to withstand rough treatment, including the abrasive action that accompanies the working down of the charge in the furnace and the pressure resulting from the superincumbent load when the coke reaches the lower zones. Resistance to the solvent action of carbon dioxide in the higher levels of the furnace is also required, and it is found that the less readily a coke reduces carbon dioxide to carbon monoxide under standard conditions of test, the higher is its shatter value, that is, the less the coke will break up when dropped onto a hard surface.

The most objectionable constituents of coke are mineral matter (which must be removed with the slag in the blast furnace), moisture, volatile matter, sulphur and phosphorus. Since coke yields a considerably higher percentage of ash than the coal from which it is made, it is customary to crush and wash the coal to remove particles of shale and other incombustible matter before coking so that the ash on the coke shall not exceed about 10%. Sulphur and phosphorus are undesirable in metallurgical coke because they enter into the iron and must be removed when the iron is converted into steel.

History of Coke.—The early history of the manufacture and application of coke made from pit coal to the smelting of iron is somewhat obscure. Because of the ravages caused in timber supplies by the expansion of the iron industry during the 16th century, a number of acts of parliament were passed between 1558 and 1584 restricting the number and location of ironworks. The attention of ironmasters was thus directed to the desirability of finding substitute fuels such as peat and coal, and a number of patents were granted from 1589 onward covering the use of stone coal, pit coal and sea coal for the manufacture of iron, which probably included the preliminary operation of smelting. The first patent definitely known to have covered the extraction of iron from the ore was obtained by Simon Sturtevant in 1611. In 1621, Lord Dudley was granted a patent in respect of the process employed by his natural son Dud Dudley who, in his *Metallum Martis* (1665), put forward exaggerated claims that the iron produced was superior to that smelted and fined by charcoal. No mention was made of any attempt to coke the coal, and it is doubtful whether, with the plant available, it would have been possible to produce iron of even moderate quality with raw coal. The first indubitable success in the substitution of coke made from coal for wood charcoal in the smelting of iron was the result of the persistent efforts of the Abraham Darbys, father and son, of Coalbrookdale in Shropshire, from 1713 to 1735.

As might be expected, the early process for the manufacture of coke closely followed that applied to the production of wood charcoal; the coal was built up in piles and set on fire, care being taken that only part of the coal was burned, the remainder being carbonized. The method was exceedingly wasteful; yields were low and it was impossible to secure uniform carbonization. Later, some control of the process was obtained by building the pile round a central brick chimney with gaps in it through which gases could enter. This was closed at the top, when necessary, by a damper. A later development was to carry out the carbonization in long piles enclosed between two brick walls provided with holes for the controlled admission of air.

By about 1850 the beehive process had almost completely ousted the foregoing. Small charges of coal were coked at the expense of all the volatiles and about one-sixth of the theoretical yield of coke in closed ovens with domed roofs. Although very inefficient, the beehive process gave excellent coke from coals having strong caking propensities. In 1858 Breckon and Dixon introduced their improved beehive oven. At the same time, efforts were made to recover by-products by coking coal in thin layers in ovens heated from below. The coke was inferior to beehive coke and as a result "patent" coke fell into disrepute and, for many years, coke made in by-product ovens was viewed with suspicion.

In 1861 E. Coppée introduced narrow ovens in which full charges of coal were carbonized; heating was carried out by burning the volatiles from the coal in vertical side flues with a regulated supply of air. The gases from the coal immediately entered the flues where they were burned, and no attempt was made to recover by-products. In other designs of oven, arrangements were made to "strip" the gases of tars and light spirits before they were returned to the heating flues.

An important advance was made in 1881 when Henry Simon of Manchester introduced a recuperative system whereby part of the heat in the burned gases from the heating flues was used to preheat the air which was supplied to the flues. As a result, higher temperatures were obtainable in the ovens, and there was a certain amount of surplus gas over and above that required to supply the heat required for carbonizing the coal.

Modern Methods of Coke Manufacture in Britain.—Coke is made either as a principal product for use in the manufacture of iron and steel at coke-oven plants, or as a by-product in the manufacture of coal gas in gasworks. In both industries, by-products in the form of ammonia, tar, benzol and other light oils are recovered; the methods of carbonization and recovery of the by-products are, however, different. Consequently the two industries must be considered separately. The making of coke as a by-product of coal gas is described in the article GAS INDUSTRY.

Coke Ovens.—A coke oven consists of a long narrow chamber, constructed of bricks containing 95% silica, from 40 to 45 ft. long, 12 to 15 ft. high and 14 to 20 in. wide, slightly tapered so that one end is about 2 in. wider than the other. The ends are closed by steel doors lined with firebrick, which can be lifted by small cranes when an oven is to be discharged. There are three or four openings in the roof through which the coal is introduced from an electrically driven charging truck running on rails along the battery of ovens.

the gas, together with some steam from the stills, just before the gas enters the saturator where the ammonia is converted to sulphate as in the direct process. The semidirect method of recovery is less economical in fuel than the direct process, for not only is steam required to operate the ammonia stills, but the gas, after it leaves the exhauster, must be reheated to avoid risks of condensation of water vapour in the saturator. The recovery of naphthalene and benzol follows the same course in both processes.

Coke and By-products, Great Britain, 1952

Item	Gasworks	Coke works	Total
Coal carbonized, 000,000 tons	27.44	25.22	52.66
Coke made " "	12.58	17.09*	29.67
Breeze " "		1.04	
Gas made, 000,000 cu.ft.	500,610	271,586	772,196
Benzol scrubbed from gas, 000,000 gal.	26.3	73.3	90.6
Motor benzol made, 000,000 gal.	11.7	32.5	44.2
Tar distilled, 000,000 tons			2.71

*Of this, coke (excluding breeze) was supplied as follows (in 000,000 tons): blast furnaces 11.67; foundries, 1.18; other industries, 3.72; shipments, 0.42.

The Carbonizing Industries in Great Britain.—More than 50,000,000 tons of coal are treated at gasworks and at coking plants every year in Great Britain, and the throughput is increasing steadily. The table gives the figures for the manufacture of coke and by-products for 1952.

See also COAL AND COAL MINING; GAS INDUSTRY; LOW-TEMPERATURE CARBONIZATION. (G. W. Hs.)

UNITED STATES

In the United States, the industry of coke making attained proportions greatly exceeding those in Great Britain, and developed on somewhat different lines.

Beehive Coking.—Beehive coking in the United States has a minor role in coke production, accounting for less than 10% of the total production of about 80,000,000 tons annually in the mid-1950s. These ovens are located at or near the coal mines and produce coke chiefly for blast-furnace and industrial purposes. Because of the higher operating costs of the beehive ovens they are shut down when the coke demand lessens. They are an important factor in meeting peak load demands for coke.

Chemical-Recovery Coke Ovens.—In the United States the term by-product was being replaced at mid-20th century by the term coal chemicals, and the coke ovens from which coal chemicals are recovered are known as chemical-recovery coke ovens. A typical modern chemical-recovery coke oven in the United States is a rectangular chamber of about 650–750 cu.ft. It has a length of about 40 ft., a height of 12 to 13 ft. and an average width (tapering 2 to 4 in. throughout the length) of 17 to 20 in. The ovens are built closely side by side in a single structure known as a battery, usually comprising 50 to 60 ovens for convenience in operation. The ovens are separated by rows of heating flues between the ovens, each row serving to heat two ovens except in the case of the flues at each end of the battery. The flues connect into the regenerators which are located immediately below each oven and which supply preheated air for combustion and receive the hot products of combustion. The heating gas is connected into the flues by a separate duct when the ovens are heated with coke-oven gas. Many of the coke ovens of the combination type are designed to be heated with coke-oven gas or blast-furnace gas (also producer gas) in which case the blast-furnace gas (or producer gas) is heated in regenerators as well as the air. Heating is carried out in half the number of flues for 20 to 30 minutes; then the system is reversed, and heating is carried on in the other half of the flues. In the so-called underjet ovens there is a basement below the oven structure so that the coke-oven gas can be easily controlled in each flue. The oven structure is built almost entirely of silica brick. This refractory, because of its rigidity under load, permits the use of higher temperatures in the flues and thus secures more rapid working and greater oven capacity than is attainable with fire-clay brick. Flue temperatures of 1,370° to 1,455° C. (2,500° to 2,650° F.) are commonly used in modern U.S. ovens, but temperatures vary depending on the rate of production or quality of coke required.

A favourite type of chemical-recovery oven in the United States is the Becker modification of the Koppers oven, the distinguishing feature of which is its provision for conducting the gases of combustion from the top of a row of vertical flues across and over the oven and down the row of flues on the other side. The crossover flues, of an inverted U shape, are in the upper part of the oven battery structure. They pass over alternate ovens only, and are generally six to eight in number, distributed across the length of the oven. Each crossover flue handles the waste gases from four to six vertical flues in the heating walls beneath, and each set of vertical flues is separated from each other set. The advantages of this type of oven are concerned chiefly with securing more uniform heating of the ovens, elimination of leakage in the combustion system and a more stable structure in the upper part of the flue wall. The heating gases burn in all of the flues in one-half of the number of walls, and when reversal takes place for the purpose of regeneration, the heating gases burn in the remaining half. This procedure is in contrast with the system where heating gases burn in one-half of the flues in each wall on each reversal. This construction and flow pattern makes for more uniform heating, end to end, of the oven walls. The old horizontal flue of large size (above the row of vertical flues) is structurally absent because of the provision of crossover flues which greatly reduce the volume of gases to be carried in any one section of that part of the oven. This allows a heavier wall structure in this region and permits the heating flues to be built up higher without risk of overheating the oven tops, resulting in more uniform coking of the oven charge.

On Dec. 31, 1953, the following numbers of chemical-recovery coke ovens of the various types were in existence in the United States:

Koppers (including Koppers-Becker)	12,036
Wilputte	2,182
Semet-Solvay	1,611
Cambria	120
Simon Carvés	40
Total	15,989

Gas Retorts and Ovens.—The production of city gas by carbonization of coal in D-shaped gas retorts and intermittent or continuous vertical retorts has practically disappeared in the United States. Although ovens of these types were once important in the gas industry, only a few isolated plants remain. Coal gas has generally been replaced by natural gas, liquefied petroleum gases or gas made from oil.

Carbonization Practice.—The United States has large reserves of relatively high-quality coking coals, most of which are located in the Appalachian region near large centres of population, where much of the steel industry is also located. The amount of coal used in chemical-recovery coke ovens annually has varied and in some years has been well over 100,000,000 tons. It is common practice to blend two or more coals for coke making. The high-volatile type (31%–38% volatile matter) is mixed in the proportion of 70% to 85% with low-volatile type (15%–22% volatile matter) in the proportion of 15%–30%. Medium-volatile type coal (23%–30% volatile matter) is sometimes included in the blend. When two or more kinds of coal are mixed together the coals are generally pulverized until at least 75% passes through a ⅛-in. screen, but when using a single high-volatile type, the crushing is generally to about 1¼ in. size. Low-volatile coal is never carbonized alone in chemical-recovery coke ovens because it develops sufficient pressure against the oven walls to distort them and cause spalling of the brickwork. Modern chemical-recovery coke ovens have a capacity of 15 to 20 tons (2,000 lb. each) with pulverized coal weighing approximately 50 lb. per cubic foot in the coke oven. The daily coking capacity of each oven is 20 to 24 tons of coal at normal rates of operation. Coal is charged into the coke ovens from the top from a car that runs on top of the coke ovens. Stamping or compressing of the coal charge is not practised in the United States. The time required to carbonize the coal is dependent mostly on the width of the oven and on the temperature of the flues. At normal rates of operation the coking time is about one hour for each inch of oven width. At the end of the coking period the hot coke, at a temperature of about 1,800° F., is pushed out of the oven into a car and is quenched with a carefully con-

trolled amount of water at a quenching station usually located beyond the end of the oven batteries. The coke is then dumped on an inclined wharf where it cools further and finally is transported by belt conveyor to a screening station and separated into sizes.

Coke is designated by its method of manufacture, such as oven coke, beehive coke and retort coke. It is also designated by the use to which it is put, as blast-furnace coke (or simply furnace coke), foundry coke, water-gas coke, domestic coke (for house heating). Another method of designation, chiefly applied to domestic coke, is according to size. The usual size classification, in the order of the largest size first, is as follows: egg, stove, nut, range, pea, breeze.

In the recovery of coal chemicals, the volatile products leaving the ovens enter a standpipe connecting into a manifold or collecting main where the first cooling of the gas and condensing of the tar takes place. After further cooling in the primary coolers and tar extractors, the ammonia is recovered by the so-called semi-direct process, in which the gases are passed through a weak solution of sulphuric acid either in specially designed low-differential saturators or spray-type ammonia absorbers. The ammonia is thus converted into solid crystalline ammonium sulphate. Light oil containing benzene, toluene, xylenes and higher boiling hydrocarbons is scrubbed from the gas by a petroleum-type absorbent oil after which the light oil is steam distilled from the scrubbing oil. The gas, having a heating value of about 530 B.T.U. per cubic foot, requires no further treatment when used for underfiring the ovens or in the steel-mill furnaces, but hydrogen sulphide and naphthalene removal are necessary for distribution in city mains.

Average annual yields of products obtained from the carbonization of coal in chemical recovery coke ovens in the United States in the 1950s were as follows:

Coke (total), per cent coal	70.1
Breeze, per cent coal	5.0
Tar, gallons per ton coal	7.9
Light oil (crude), gallons per ton coal	2.9
Ammonium sulphate, pounds per ton coal	20.1
Gas, total cubic feet per ton coal	10,190

Disposal of Coke and Gas.—Consumption of coke at blast-furnace plants accounted for 89% of the total coke produced in the United States in the mid-1950s, and an additional approximate 4% of the coke was used in foundries, making a total of roughly 93% used in metallurgical processes. The rest of the coke produced was used as follows: 2% for water-gas and producer-gas manufacture; 2% for industrial purposes; 2% for residential heating and 1% export.

Approximately 35% to 40% of the total gas produced was returned to the coke ovens for underfiring; 48% of the total gas produced was used in steel mills or allied plants and 9% was distributed through city mains.

"COKE OF NORFOLK": *see* LEICESTER OF HOLKHAM, THOMAS WILLIAM COKE, EARL OF.

COL, in physical geography, generally any distinct depression upon a high water-parting offering easy passage from one valley to another. There are numerous cols on the Franco-Italian frontier, *e.g.*, the Little St. Bernard (2,188 ft.) which carries the road from the Dora Baltea to the upper Isère. The col (Fr. for "neck," Lat. *collum*) is usually formed by the headwaters of streams eating backwards towards one another and lowering the water-parting between their valley-heads. In early military operations, the most convenient col controlled the route of the army's movement.

On the weather map a col is an area in which the pressure is neither high nor low and where the winds are calm or light and variable. This condition is possible only between two "highs" and two "lows." This feature is sometimes called a "neutral point" or "saddle point." (*See* CYCLONE; ANTICYCLONE.)

COLBERT, JEAN BAPTISTE (1619–1683), French statesman, was born at Reims, where his father and grandfather were merchants. Through a family connection with Michel le Tellier, secretary of State for war, Colbert obtained a place in the war office before he was 20 and presently became private secretary to the minister. Twelve years later he became agent to Mazarin, driven from Paris (1651) during the supremacy of the Condé family, with the duty of keeping him informed of the progress of events. On his return, Mazarin gratified his agent with honours and places for various members of his family, and gave him his entire confidence. After Mazarin's death, Colbert secured the favour of Louis XIV. and became the chief power in the administration, though he did not at first hold an official position.

The king's new adviser set to work at once to reform the chaotic financial administration of France. He began by striking at the *surintendant*, Nicolas Fouquet, and secured his disgrace. The office of *surintendant* was abolished, and the control of finance was vested for a time in a royal council. Colbert, who contented himself with the title of *intendant*, was the ruling spirit of this council, but did not take over nominal direct control until 1665, when he was made controller-general. His first measures for cleansing the financial administration were ruthless enough. He set up a tribunal to deal with officials who intercepted money due to the treasury. Many were condemned to death, though the death sentences were not carried out; some 4,000 were compelled to disgorge their gains. The tribunal was disbanded in 1665, but it had purified the service. The public debt was handled by drastic methods. Some series of bonds were repudiated on the ground that only a small part of the money had been paid in; others were cancelled by paying the original sum invested less the interest paid. Colbert did not propose the abolition of privilege, but he drew into the net of taxation many who had hitherto escaped by revising the application of the *taille*, or direct tax. Indirect taxes were increased and the tariff revised in 1664, as part of a protective system. The various dues which existed among the provinces could not be swept away, but, although internal fiscal barriers were not destroyed, a measure of uniformity was secured in central France. His reforms in the farming out and collection of taxes and the jealous watch kept on the officials brought large sums into the treasury.

Colbert then turned his attention to the general increase of wealth by the encouragement of industry. He had a narrow conception of prosperity, which in his mind could not be real if neighbouring countries were prosperous. And in his encouragement of industry and trade he used the same minute method of centralized regulation which had brought order into the fiscal system. Every detail was to be controlled. This minute regulation probably accounts for the failure of the great trading corporations which he set up in 1664 for trading in India and in America (the East Indies and West Indies companies), while the British and Dutch monopolistic trading companies, with their operations untrammelled by the home government, prospered. He set up model factories, either financed by State funds as in the case of the Gobelins (founded 1667) or by concessionaries. He sought to standardize the production of staple commodities for all producers; faulty workmanship or deviation from the standard was punished by fine and by exposure in the pillory. These regulations hampered industry and annoyed the producers, and the encouragement given to industry tended to starve agriculture. French industry was to be developed by administrative measures and by a high protective tariff, and the proceeds accruing to the State were to be used for the development of communications and of external trade. The roads and canals were improved. The great canal of Languedoc was planned and constructed by Pierre Paul Riquet (1604–80) under Colbert's patronage.

The greatest and most lasting of Colbert's achievements was the establishment of the French marine. He became minister of the marine in 1669; then, in addition, of the colonies and the king's palace. The royal navy owed all to him, for the king thought only of military exploits. Colbert reconstructed the works and arsenal of Toulon, founded the port and arsenal of Rochefort, and the naval schools of Rochefort, Dieppe, and St. Malo, and fortified, with some assistance from Vauban (who, however, belonged to the party of his rival Louvois), among other ports those

of Calais, Dunkirk, Brest, and Havre. To supply it with recruits he invented his system of classes, by which each seaman, according to the class in which he was placed, gave six months' service every three or four or five years. For three months after his term of service he was to receive half-pay; pensions were promised; and, in short, everything was done to make the navy popular. There was one department, however, that was supplied with men on a very different principle. The galleys used in the Mediterranean service required oarsmen. Colbert wrote to the judges requiring them to sentence to the oar as many criminals as possible; and the convict, once chained to the bench, the expiration of his sentence was seldom allowed to bring him release. Vagrants, contraband dealers, political rebels, Turkish, Russian, and negro slaves, and poor Iroquois Indians, whom the Canadians were ordered to entrap, were pressed into that terrible service. By these means the benches of the galleys were filled, and Colbert took no thought of the long agony of those who filled them.

Encouragement was given to the building of ships for the mercantile marine by allowing a premium on those built at home, and imposing a duty on those brought from abroad; and as French workmen were forbidden to emigrate, so French seamen were forbidden to serve foreigners on pain of death.

Colbert was a patron of art and literature. He possessed a fine private library, rich in valuable manuscripts. He founded the academy of sciences, the observatory, which he employed Claude Perrault to build and brought G. D. Cassini (1625–1712) from Italy to superintend, the academies of inscriptions and medals, of architecture, and of music, the French academy at Rome, and academies at Arles, Soissons, Nîmes, and many other towns, and he reorganized the academy of painting and sculpture which Richelieu had established. He was a member of the French academy. In 1673 he presided over the first exhibition of the works of living painters; and he enriched the Louvre with hundreds of pictures and statues. He gave many pensions to men of letters, among whom we find Molière, Corneille, Racine, Boileau, P. D. Huet (1630–1721) and Antoine Varillas (1626–96), and even foreigners, as Huyghens, Vossius the geographer, Carlo Dati the Dellacruscan, and Heinsius the great Dutch scholar.

Colbert's industry was colossal. He found time to do something for the better administration of justice (the codification of ordinances, the diminishing of the number of judges, the reduction of the expense and length of trials for the establishment of a superior system of police) and even for the improvement of the breed of horses and the increase of cattle. As superintendent of public buildings he enriched Paris with boulevards, quays, and triumphal arches; he relaid the foundation stone of the Louvre, and brought Bernini from Rome to be its architect; and he erected its splendid colonnade upon the plan of Claude Perrault, by whom Bernini had been replaced. He was not permitted, however, to complete the work, being compelled to yield to the king's preference for residences outside Paris, and to devote himself to Marly and Versailles.

Amid all these public labours he directed personally the management of every farm on his estates. He died extremely rich and left fine estates all over France. He had been created marquis de Seignelay, and for his eldest son he obtained the reversion of the office of minister of marine; his second son became archbishop of Rouen; and a third son, the marquis d'Ormoy, became superintendent of buildings.

To carry out his reforms, Colbert needed peace and consistently advocated it, except in the case of the Dutch War, for which his commercial policy was partly responsible; but the war department was in the hands of his great rival Louvois, whose influence gradually supplanted that of Colbert with the king. Louis decided on a policy of conquest. He was deaf also to all the appeals against the other forms of his boundless extravagance which Colbert ventured to make (*Lettres*, vol. ii.). Thus, only a few years after he had begun to free the country from the weight of the loans and taxes which crushed her to the dust, Colbert was forced to heap upon her a new load of loans and taxes heavier than the last. Depressed by his failure, deeply wounded by the king's favour for Louvois, and worn out by overwork, his strength gave way at a comparatively early age.

Colbert was a great statesman, who did much for France. Nevertheless, his rule was a very bad example of over-government. He did not believe in popular liberty; the parlements and the states-general received no support from him. The technicalities of justice he never allowed to interfere with his plans; and he did not hesitate to shield his friends. He trafficked in public offices for the profit of Mazarin and in his own behalf. He caused the suffering of thousands in the galleys. There was indeed a more human side to his character, shown to his own family, but to all outside he was "the man of marble." Madame de Sévigné called him "the North Star." To diplomacy he never pretended.

BIBLIOGRAPHY.—The most thorough student of Colbert's life and administration was Pierre Clément, member of the Institute, who in 1846 published his *Vie de Colbert*, and in 1861 the first of the 9 vols. of the *Lettres, instructions et mémoires de Colbert*. The historical introductions prefixed to each of these volumes have been published by Mme. Clément under the title of the *Histoire de Colbert et de son administration*, 3rd ed. (1892). The best short account of Colbert as a statesman is that in Lavisse, *Histoire de France* (1905), which gives a thorough study of the administration. *See* also Benôit du Rey, *Recherches sur la politique coloniale de Colbert* (1902). Among Colbert's papers are *Mémoires sur les affaires de finance de France* (written about 1663), a fragment entitled *Particularités secrètes de la vie du Roy*, and other accounts of the earlier part of the reign of Louis XIV.

COLBERT DE CROISSY, CHARLES, MARQUIS (1625–1696), French diplomatist, like his elder brother Jean Baptiste Colbert, began his career in the office of the minister of war, Le Tellier. In 1656 he bought a counsellorship at the parlement of Metz, and in 1658 was appointed intendant of Alsace and president of the newly-created sovereign council of Alsace. In this position he had to reorganize the territory recently annexed to France. The steady support of his brother at court gained for him several diplomatic missions—to Germany and Italy (1659–61). In 1662 he became marquis de Croissy and *président à mortier* of the parlement of Metz. After various intendancies, at Soissons (1665), at Amiens (1666) and at Paris (1667), he turned definitely to diplomacy. In 1668 he represented France at the conference of Aix-le-Chapelle; and in August of the same year was sent as ambassador to London, where he was to negotiate the definite treaty of alliance with Charles II. He arranged the interview at Dover between Charles and his sister Henrietta of Orleans, gained the king's personal favour by finding a mistress for him, Louise de Kérouaille, maid of honour to Madame, and persuaded him to declare war against Holland. The negotiation of the treaty of Nijmwegen (1676–78) still further increased his reputation as a diplomatist, and Louis XIV. made him secretary of state for foreign affairs after the disgrace of Arnauld de Pomponne, brought about by his brother, 1679. He at once assumed the entire direction of French diplomacy. It was he, not Louvois, who formed the idea of annexation during a time of peace, by means of the chambers of reunion. He had outlined this plan as early as 1658 with regard to Alsace. His policy at first was to retain the territory annexed by the chambers of reunion without declaring war, and for this purpose he signed treaties of alliance with the elector of Brandenburg (1681), and with Denmark (1683); but the troubles following upon the revocation of the Edict of Nantes (1685) forced him to give up his scheme and to prepare for war with Germany (1688). The negotiations for peace had been begun again when he died, on July 28, 1696.

BIBLIOGRAPHY.—His papers, preserved in the *Archives des affaires étrangères* at Paris, have been partially published in the *Recueil des instructions données aux ambassadeurs et ministres de France* (since 1884). *See* especially the volumes:—*Autriche* (t.i.), *Suède* (t.ii.), *Rome* (t.vi.), *Bavière* (t.viii.), *Savoie* (t.xiv.), *Prusse* (t.xvi.). Other documents have been published in Mignet's *Négociations relatives à la succession d'Espagne*, vol. iv., and in the collection of *Lettres et négociations . . . pour la paix de Nimègue, 1676–77* (La Haye, 1710). In addition to the *Mémoires* of the time, *see* Spanheim, *Relation de la cour de France en 1690*, edit. E. Bourgeois (Lyons, 1900); Baschet, *Histoire du depôt des affaires étrangères*; C. Rousset, *Histoire de Louvois* (1863); E. Bourgeois, "Louvois et Colbert de Croissy," in the *Revue Historique*, vol. xxxiv. (1887); A. Waddington, *Le Grand Électeur et Louis XIV.* (1905); G. Pagès, *Le Grand Électeur et Louis XIV.* (1905).

COLBURN, HENRY (d. 1855), British publisher. In 1814 he originated the *New Monthly Magazine*, of which at various times Thomas Campbell, Bulwer Lytton, Theodore Hook and Harrison Ainsworth were editors. Colburn published in 1818 *Evelyn's Diary*, and in 1825 the *Diary of Pepys*, edited by Lord Braybrooke, paying £2,200 for the copyright. He also issued Disraeli's first novel, *Vivian Grey*. His business was taken over in 1841 by Messrs. Hurst and Blackett. Henry Colburn died on Aug. 16, 1855.

COLBY, FRANK MOORE (1865–1925), U.S. editor, was born in Washington, D.C., Feb. 10, 1865. He received from Columbia university the degrees A.B. (1888) and A.M. (1889). He was acting professor of history at Amherst college (1890–91), lecturer and instructor in history and economics at Columbia university and Barnard college (1891–95) and professor of economics at New York university (1895–1900). In 1893 he joined the editorial staff of *Johnson's Universal Cyclopaedia*. In 1898 he became editor of *The International Year Book*, and he was one of the editors of *The International Cyclopaedia* and of the first and second editions of *The New International Encyclopaedia*. He served as American editor of *Nelson's Encyclopaedia* (1905–06), and after 1907 as editor of *The New International Year Book*.

Colby died in New York city, March 3, 1925. He wrote, among other works, *Imaginary Obligations* (1904); *Constrained Attitudes* (1910) and *The Margin of Hesitation* (1922).

COLCHAGUA, a province of central Chile, bounded north by Santiago and O'Higgins, east by Argentina, south by Curicó and west by the Pacific. Its area is 3,255 sq.mi.; population (1940 census) 138,036; (1951 est.) 135,775.

The great longitudinal valley of Chile cuts across the central part of the province, providing a considerable area excellently suited to the production of crops and livestock. Good range land exists in both the coastal mountains and along the lower slopes of the Andes. The principal river is the Rapel which, in its lower reaches, forms a part of the northern boundary of the province. Near the Argentine frontier, on one of the principal tributaries of the Rapel, are the hot springs of San Fernando, accessible by car from San Fernando, capital of Colchagua. The State central railway from Santiago to Puerto Montt passes through San Fernando (83 mi. S. of Santiago), and a branch line extends west to the popular ocean resort of Pichelemu. San Fernando is one of the several towns founded in 1742 by the governor-general José de Manso.

COLCHESTER, CHARLES ABBOT, 1ST BARON (1757–1829), was born in Abingdon, and educated at Westminster school and Oxford. In 1795, after having practised 12 years as a barrister, he was appointed clerk of the rules in the king's bench and elected member of parliament. To his efforts were due the establishment of the Royal Record commission, the reform of the system which had allowed the public money to lie for long periods in the hands of the public accountants, by charging them with payment of interest, and, most important of all, the act for taking the first census (1801).

In March 1801 Abbot became chief secretary and privy seal for Ireland; and in 1802 he was chosen speaker of the house of commons. In response to an address of the commons, he became Baron Colchester, with a pension of £4,000. He died on May 8, 1829.

COLCHESTER, municipal borough, Essex, England; 52 mi. northeast of London, on the river Colne. Pop. (1951) 57,436. Area 18.8 sq.mi. In early British and Roman history it was known as Camulodunum, the capital of the British chief Cunobelin, and is named on his coins. After his death and the Roman conquest, Claudius established a municipality of discharged soldiers. It was stormed and burned A.D. 61 in the rising of Boadicea (*q.v.*), but soon became one of the chief towns in Roman Britain. The town is named after Camulos, the Celtic Mars. Roman sculptures and inscriptions have been discovered and its walls and the guardroom of the principal gate can still be traced. The Domesday book mentions 276 burgesses and land *in commune burgensium*. The ruined castle-keep built by William I about 1080 is quadrangular, turreted at the angles, and is the largest of its kind in England. In the castle is a museum of Roman and other antiquities. The Augustinian priory of St. Botolph (early 12th cent.) retains part of the fine Norman west front (in which Roman bricks occur), and of the nave arcades; and there is the restored gateway of the Benedictine monastery of St. John, a beautiful specimen of Perpendicular work, embattled, flanked by spired turrets, and covered with panel work. The church of Holy Trinity has an apparently pre-Norman tower.

The first charter given in 1189 granted freedom of passage and pontage through England, free warren, fishery and custom as in the time of Henry I. The charters were confirmed and new grants obtained in 1447 and 1535. Colchester returned two members to parliament from 1295 until 1885. Fairs were granted by Richard I in 1189 to the hospital of St. Mary Magdalene, and by Edward II in 1319 on the eve of St. Denis and the six following days. In the 13th century Colchester was an important port, its ships plying to Winchelsea and France. Elizabeth and James I encouraged Flemish settlers in manufacture of baize ("bays and says"). Both Camden and Fuller mention the trade in barrelled oysters and candied eringo-root. The town was held, apparently against the citizens' will, by Royalists in 1648 against Fairfax, and it was fined in consequence by the parliament.

Charles I granted a fresh charter, which was amended in 1653 and a new one granted in 1663; this one remaining in force with modifications until 1741. In 1763 George III made the borough a renewed grant of its liberties. The town has long been an important military centre and is the headquarters of the 4th division and East Anglia area. There is a free grammar school (founded 1539). Castle park is a public ground surrounding the castle. Colchester is the centre of an agricultural district, and has weekly corn and cattle markets, besides extensive nurseries and a large rose-growing industry. The oyster fisheries at the mouth of the Colne belong to the corporation, and are held on lease by the Colne Fishery company. The harbour, with quayage at the suburb of Hythe, is controlled by the corporation. Since 1918 the municipal borough of Colchester together with the rural districts of Lexden and Winstree (except the detached portion of Inworth parish) form the Colchester parliamentary division of Essex.

Colchester was made the see of a bishop suffragan by Henry VIII, and two bishops were in succession appointed by him; no further appointments, however, were made until the suffragan see was re-established under Victoria.

COLCHICUM, the meadow saffron, or autumn crocus (*Colchicum autumnale*), a perennial plant of the family Liliaceae, found wild in rich, moist meadowland in England and Ireland, in middle and southern Europe and in the Swiss Alps. It has pale purple flowers, rarely more than three in number; the perianth is funnel-shaped, and produced below into a long slender tube, in the upper part of which the six stamens are inserted. The ovary is three-celled, and lies at the bottom of this tube. The leaves are three or four in number, flat, lanceolate, erect and sheathing; and there is no stem. Propagation is by the formation of new corms from the parent corm, and by seeds. The latter are numerous, round, reddish-brown and of the size of black mustard-seeds. The corm of the meadow saffron attains its full size in June or early in July. A smaller corm is then formed from the old one, close to its root; and this in September and October produces the crocus-like flowers. In the succeeding January or February it sends up its leaves, together with the ovary, which perfects its seeds during the summer. The young corm grows continuously, till in the following July it attains the size of a small apricot. The parent corm remains attached to the new one, and keeps its form and size till April in the third year of its existence, after which it decays. In some cases a single corm produces several new plants during its second spring by giving rise to immature corms. *C. autumnale* and its numerous varieties, as well as other species of the genus, are well known in cultivation, forming some of the most beautiful of autumn-flowering plants.

Colchicum or colchicine, applied to the skin, causes pain and congestion; inhaled, causes violent sneezing; and taken internally.

increases the amount of bile poured into the intestine. In larger doses it is a violent gastrointestinal irritant, causing severe colic, vomiting, diarrhoea, haemorrhage from the bowel and ultimately death from collapse. This is accelerated by a depressant action upon the heart and nervous system similar to that produced by veratrine and aconite. The sole medical use of colchicum is in gout. It has an extraordinary power over the pain of acute gout, lessens the severity and frequency of the attacks when given continuously between them, and benefits such symptoms of gout as eczema, bronchitis and neuritis, though inoperative against them when not of gouty origin. The drug is generally given as *vinum colchici*, in doses of 10 to 30 minims. It is apt to render the patient low-spirited and tearful and must be given only with great care. In colchicum poisoning, empty the stomach, give white of egg, olive or salad oil and water. Use hot bottles and stimulants, especially trying to counteract the cardiac depression by atropine, caffeine, strophanthin, etc.

Colchicum is a specific for separation of chromosomes. The product is much used in genetics and plant breeding to produce a doubling of the chromosomes. Most of the U.S. supply ordinarily comes from the Netherlands, Italy, Yugoslavia and Hungary.

COLCHIS, in ancient geography, a nearly triangular district of Asia Minor, at the eastern extremity of the Black sea, bounded on the north by the Caucasus, which separated it from Asiatic Sarmatia, east by Iberia, south by the Montes Moschici, Armenia and part of Pontus and west by the Euxine. The name of Colchis first appears in Aeschylus and Pindar. It was inhabited by a number of tribes whose settlements lay chiefly along the shore of the Black sea. These tribes differed so completely in language and appearance from the surrounding nations that the ancients originated various theories to account for the phenomenon. Herodotus believed them to have sprung from the relics of the army of Sesostris (*q.v.*), and thus regarded them as Egyptians. Apollonius Rhodius (*Argon,* iv, 279) states that the Egyptians of Colchis preserved as heirlooms a number of wooden κύρβεις (tablets) showing seas and highways with considerable accuracy. It is quite possible that there was an ancient trade connection between the Colchians and the Mediterranean peoples. We learn that women were buried, while the corpses of men were suspended on trees. The principal coast town was the Milesian colony of Dioscurias (Roman Sebastopolis; mod. Sukhum-Kaleh), the ancient name being preserved in the modern C. Iskuria. The chief river was the Phasis (mod. Rion).

Colchis was celebrated in Greek mythology as the destination of the Argonauts, the home of Medea and the special domain of sorcery. Several Greek colonies were founded there by Miletus. It seems to have been incorporated in the Persian empire, though the inhabitants evidently enjoyed a considerable degree of independence; in this condition it was found by Alexander the Great when he invaded Persia. From this time till the era of the Mithradatic wars nothing is known of its history. At the time of the Roman invasion it seems to have paid a nominal homage to Mithradates the Great and to have been ruled over by Machares, his second son. On the defeat of Mithradates by Pompey, it became a Roman province. After the death of Pompey, Pharnaces, the son of Mithradates, rose in rebellion against the Roman yoke, subdued Colchis and Armenia and made head, though but for a short time, against the Roman arms. After this Colchis was incorporated with Pontus, and the Colchians are not again alluded to in ancient history till the 6th century. It had been specially garrisoned by Justinian, first under Peter, a Persian slave, and subsequently under Johannes Tzibos, who built Petra on the coast as the Roman headquarters. Tzibos took advantage of the extreme poverty of the inhabitants to create a Roman monopoly by which he became a middleman for all the trade, both export and import. Chosroes I succeeded in capturing Petra (A.D. 541). The missionary zeal of the Zoroastrian priests soon caused discontent among the Christian inhabitants of Colchis, and Gobazes, perceiving that Chosroes intended to Persianize the district, appealed to Rome, with the result that in 549 one Dagisthaeus was sent out with 7,000 Romans and 1,000 auxiliaries of the Tzani (Zani, Sanni). The "Lazic war" lasted till 556 with varying success. Petra was recaptured in 551, and Archaeopolis was held by the Romans against the Persian general Mermeroes. Gobazes was assassinated in 552, but the Persian general Nachoragan was heavily defeated at Phasis in 553.

By the peace of 562 the district was left in Roman possession, but during the next 150 years it is improbable that the Romans exercised much authority over it. In 697 we hear of a revolt against Rome led by Sergius the Patrician, who allied himself with the Arabs. Justinian II in his second period of rule sent Leo the Isaurian, afterward emperor, to induce the Alans to attack the Abasgi. The Alans invaded Lazica, and, probably in 712, a Roman and Armenian army laid siege to Archaeopolis. On the approach of a Saracen force they retired, but a small plundering detachment was cut off. Ultimately Leo joined this band and aided by the Apsilian chief Marinus escaped with them to the coast.

From the beginning of the 14th to the end of the 17th century Colchis was governed by an independent dynasty, the Dadians, which was succeeded by a semi-independent dynasty, the Chikovans, who by 1838 had submitted to Russia, though they retained a nominal sovereignty. In 1866 the district was finally annexed by Russia. *See* GEORGIA.

For the kings *see* Stokvis, *Manuel d'histoire,* i, 83.

COLCOTHAR (adapted in Romanic languages from Arabic *golgotar,* which was probably a corruption of the Gr. χάλκανθος from χαλκός, copper, ἄνθος, flower; *i.e.,* copper sulphate), a name given to the brownish-red ferric oxide residue obtained in the preparation of fuming sulphuric (Nordhausen) acid by the dry distillation of ferrous or ferric sulphate. It is used as a polishing powder by jewellers and as the pigment Indian red. It is also known as Crocus Martis, *caput mortuum,* Prussian red, rouge, etc.

COLD, subjectively the sensation which is excited by contact with a substance whose temperature is lower than the normal; objectively a quality or condition of material bodies which gives rise to that sensation. Whether cold, in the objective sense, was to be regarded as a positive quality or merely as absence of heat was long a debated question. Thus Robert Boyle, who does not commit himself definitely to either view, says, in his *New Experiments and Observations Touching Cold,* that "the dispute which is the *primum frigidum* is very well known among naturalists, some contending for the earth, others for water, others for the air, and some of the moderns for nitre, but all seeming to agree that there is some body or other that is of its own nature supremely cold and by participation of which all other bodies obtain that quality." But with the general acceptance of the dynamical theory of heat, cold naturally came to be regarded as a negative condition, depending on decrease in the amount of the molecular vibration that constitutes heat.

The question whether there is a limit to the degree of cold possible, and, if so, where the zero must be placed, was first attacked by the French physicist G. Amontons in 1702–03, in connection with his improvements in the air thermometer. In his instrument temperatures were indicated by the height at which a column of mercury was sustained by a certain mass of air, the volume or "spring" of which of course varied with the heat to which it was exposed. Amontons therefore argued that the zero of his thermometer would be that temperature at which the spring of the air in it was reduced to nothing. On the scale he used the boiling point of water was marked at 73 and the melting point of ice at 51½, so that the zero of his scale was equivalent to about −240° on the Centigrade scale. This remarkably close approximation to the modern value of −273° for the zero of the air thermometer was further improved on by J. H. Lambert (*Pyrometrie,* 1779), who gave the value −270° and observed that this temperature might be regarded as absolute cold. Values of this order for the absolute zero were not, however, universally accepted about this period. Laplace and Lavoisier, for instance, in their treatise on heat (1780), arrived at values ranging from 1,500° to 3,000° below the freezing point of water, and thought that in any case it must be at least 600° below, while John Dalton in his *Chemical Philosophy* gave ten calculations of this value, and finally adopted −3,000° C. as the natural zero of temperature. After J. P. Joule

had determined the mechanical equivalent of heat, Lord Kelvin approached the question from an entirely different point of view, and in 1848 devised a scale of absolute temperature which was independent of the properties of any particular substance and was based solely on the fundamental laws of thermodynamics (*see* HEAT and THERMODYNAMICS). It followed from the principles on which this scale was constructed that its zero was placed at −273°, at almost precisely the same point as the zero of the air-thermometer.

In nature the realms of space, on the probable assumption that the interstellar medium is perfectly transparent and diathermanous, must, as was pointed out by W. J. Macquorn Rankine, be incapable of acquiring any temperature, and must therefore be at the absolute zero. That, however, is not to say that if a suitable thermometer could be projected into space it would give a reading of −273°. On the contrary, not being a transparent and diathermanous body, it would absorb radiation from the sun and other stars, and would thus become warmed. (*See* J. H. Poynting, "Radiation in the Solar System," *Phil. Trans.* A, 1903). The French physicists of the early part of the 19th century held a different view, and rejected the hypothesis of the absolute cold of space. Fourier, for instance, postulated a fundamental temperature of space as necessary for the explanation of the heat-effects observed on the surface of the earth, and estimated that in the interplanetary regions it was little less than that of the terrestrial poles and below the freezing-point of mercury, though it was different in other parts of space (*Ann. chim. phys.*, 1824, 27, pp. 141, 150). C. S. M. Pouillet, again calculated the temperature of interplanetary space as −142°C. (*Comptes rendus*, 1838, 7, p. 61), and Sir John Herschel as −150°.

To attain the absolute zero in the laboratory, that is, to deprive a substance entirely of its heat, is a thermodynamical impossibility, and the most that the physicist can hope for is an indefinitely close approach to that point. The lowest steady temperature obtainable by the exhaustion of liquid hydrogen is about −262° C. (11° Abs.), and the liquefaction of helium by Prof. Kamerlingh Onnes in 1908 yielded a liquid having a boiling-point of about 4° Abs. which on exhaustion should bring us to within about 1° of the absolute zero. Liquid helium has since been solidified by W. H. Keesom (1926) at 1.13° Abs. under a pressure of 25 atmos. The freezing point rises to 4.2° Abs. under a pressure of 140 atmos. (*See* LIQUEFACTION OF GASES.)

COLD, COMMON. The term "cold" is applied by physicians and laymen alike to various acute, subacute and even chronic maladies affecting both the upper and the lower portions of the respiratory tract. Investigators of this condition usually limit the term to a condition commonly described as coryza or a cold in the head. Typical symptoms of such colds are sneezing, watery nasal discharge, nasal stuffiness and a dryness or an irritation of the membranes lining the nose and throat. The onset is usually accompanied by a sensation of chilliness. In the early stages of the acute cold, nasal discharge is profuse and watery but in two or three days becomes thicker and mucopurulent. Involvement of the paranasal sinuses and the lower portions of the respiratory tract with coughing is common.

Colds and their complications are responsible for more illness and disability than all other diseases combined. A survey conducted by the American Institute of Public Opinion found that in one week of November colds were reported in one-third of U.S. homes. Thus, during this particular week, approximately one person in seven throughout the country was afflicted with a cold. A corresponding survey for a week in October revealed that one-fourth of all families reported colds.

Other surveys indicate that approximately 75% of the people have at least one cold each year, 25% have four or more and the average is between two and three per person per year. A ten-year record of illness among employees of the Edison Illuminating Co., covering an average of 100,000 employees annually, showed that 54% of the absences from sickness were caused by the respiratory group of diseases. These and other studies indicate that the common cold, its complications and related conditions cause more loss of time in industry than all other illnesses together. The annual cost in the U.S. (economic loss and expenditures for drugs and medical and hospital services caused by the common cold and its complications) has been estimated as between $2,000,000,000 and $3,000,000,000.

Cause.—As the name suggests, colds are widely believed to be caused by chilling. In some persons chilling does produce symptoms of sneezing and coryza. Physicians call this condition vasomotor rhinitis, but to the average person it is a "cold in the head." Hay fever (*q.v.*), another quite similar condition, is caused by an allergy or hypersensitivity of the nasal mucous membranes to some substance in the air, such as pollen of plants, grasses or trees. Unquestionably many attacks of hay fever are mistaken for colds, particularly when they occur in the spring of the year.

Observations of the common cold indicate that at least some colds are communicable; in fact, the widespread colds which occur in several waves throughout the year, usually in the early fall, in midwinter and in early spring, are of this type. Investigations of the cause of this type of cold seem to indicate that a majority are caused by a filterable virus (*q.v.*), a germ which is smaller than bacteria, will pass through pores of a porcelain filter and is invisible with the ordinary microscope. The first experiments which suggested a virus as a cause of colds were performed by Walther Kruse in 1914 in the Institute of Hygiene in Leipzig, Ger. This work was repeated and confirmed by Maj. George Foster of the medical corps of the U.S. army in 1916. Beginning in the early 1920s more extensive and definitive studies of this virus were carried out by A. R. Dochez and associates in the Presbyterian hospital in New York city and by investigators at Johns Hopkins university, Baltimore, Md.

The nature of this virus is similar to that of other known viruses, such as those which cause smallpox, chickenpox, mumps, rabies and distemper. It will grow and multiply in the laboratory and remain alive for at least three years. It will remain infective after 15 subcultures on artificial media. One drop of the solution containing the virus is sufficient to give a man or a chimpanzee a typical head cold. The usual symptoms of these virus colds in human subjects are stuffiness of the nose, sneezing, watery nasal discharge, dryness of the throat, occasional headaches and mild general symptoms. The body temperature is rarely elevated and the usual duration is four to five days. Mild colds occur in subjects carefully isolated from all contact with other persons. In others, this acute process is usually followed by secondary infections with other germs which happen to be present in the nose and throat. The secondary infections, which usually persist for two or three weeks, are accompanied by a thick yellow discharge that may involve the sinuses.

Bacteria of various types have also been described as a cause of colds. Unquestionably, bacteria do produce primary infections of the respiratory tract with symptoms typical of colds. Their major role, however, seems to be that of secondary invaders following virus colds. Climate is much less a factor in the occurrence of colds than is generally supposed. Studies by the U.S. public health service show that the attack rate of colds in college students and family groups in various parts of the country are remarkably uniform and show no consistent relationship to latitude, longitude or climate. These studies also show surprising similarity in the time of occurrence of colds in various sections of the country. Studies in isolated arctic communities indicate that epidemics of colds are related not to temperature but to contact with infected persons from the outside world. In the tropics colds are less common and less severe than in the temperate zones, but they do occur and in general present a miniature picture of colds in the United States.

Complications.—The importance of colds lies not only in the colds themselves but also in their complications. An uncomplicated cold runs a short, relatively mild course of a few days' duration. The complications, however, are numerous and important. Of these, the most common are sinusitis, otitis media and infections of the lower respiratory tract such as laryngitis, tracheitis, bronchitis and pneumonia. Closely allied but distinct disease entities are influenza, tonsillitis and tuberculosis. The paranasal sinuses all are connected with the nose and are lined by mucous

membrane which is continuous with the membrane of the nose. Some inflammation of the sinuses, therefore, probably follows most if not all acute head colds. These are of importance, however, only when secondary infections occur and drainage is inadequate. Treatment of infected sinuses is a problem for the physician.

Infection of the middle ear (otitis media) occurs from the nose and throat by the way of the Eustachian tube. Formerly otitis media was often complicated by mastoid infection, but this has been controlled by penicillin, other antibiotics or the sulfonamide drugs. Laryngitis, tracheitis, bronchitis and pneumonia usually follow infections of the upper respiratory tract.

Prevention.—Natural resistance, possibly with a hereditary element, plays an important role in a person's susceptibility to colds. Studies from Cornell university (Ithaca, N.Y.) indicate that 25% of the students have approximately 75% of the colds in that institution. In many individuals, however, susceptibility seems to vary over a period of several years. Within the nose nature provides various defensive mechanisms against infection. These include the tiny hairs at the entrance of the nasal passages, the mucous secretions of the membranes lining the nose and the cilia—microscopic hairlike projections of the cells lining the nose. These cilia are in constant motion, picking up particles of foreign material and carrying them to the pharynx from which they are discharged or swallowed. It is important that we do not destroy or interfere with these natural defensives.

The prevention of communicable colds should be possible by the avoidance of exposure to persons with colds. Unfortunately, under the conditions of modern life this is impossible. However, the degree of exposure can be reduced by keeping away from persons who have colds; by prohibiting infected persons from associating with infants; by thorough washing of the hands before meals and after contact with objects likely to contain infective material; by keeping the hands away from the nose and mouth; by routine sterilization of dishes and silverware; and by use of individual drinking glasses even within the family. The avoidance of chilling, particularly for persons who lead relatively sedentary indoor lives, is a precautionary measure of value. Adequate clothing and shoes to keep the body warm and dry are important, especially for children. Places of work and residences should be warm and free from draft, but not overheated. The ventilation of sleeping quarters should be regulated according to the outside atmospheric condition, having in mind that drafts are undesirable and that sleep is most restful where the atmosphere is cool rather than warm or cold. Exercise and cool or cold showers help to keep the circulatory system in good tone and better able to adjust to the changes produced by chilling.

Vitamins and various dietary measures are widely advocated and advertised for the prevention of colds, but there are no conclusive scientific studies or records which indicate that any special diet or the addition of vitamins to adequate, well-balanced diets have this effect. Vaccines have long been used for the prevention of colds. In general, they consist of killed bacteria of the types usually found in the nose and throat during colds. Some of these vaccines are given by mouth, some by hypodermic injection and a few by spraying into the nose. Medical journals contain many papers reporting benefits from these vaccines. However, a number of carefully controlled studies have been conducted in which half the subjects received vaccine while the other half, chosen at random and without their own knowledge, received exactly the same treatment but were given injections, capsules or nasal sprays which contained no vaccine. The following important conclusions can be drawn from these studies: that the subjects who received the vaccines had as many colds as the subjects in the control groups; that the subjects in both groups reported considerably fewer colds than they thought they had had during the previous year. In fact, many subjects in the control groups were convinced that the treatments which they received were beneficial in the prevention of colds. Various antiseptics are recommended, including sprays, nose drops, gargles and mouth washes. Antiseptics do not act to kill germs instantaneously; only mild antiseptics can be tolerated by the membranes of the nose and throat, and these can be brought in contact with only a small portion of these membranes and for only a few seconds at a time. There is therefore no reason to think, and no scientific evidence, that antiseptics are of any value for the prevention of colds or other respiratory infections. On the contrary, there is danger that at least some of these preparations interfere with the protective action of the cilia and mucous secretions normally operating in the nose. Sterilization of the air by ultra-violet light or chemical vapours is theoretically sound but impractical for general use.

Treatment.—An acute infectious cold usually runs a course of three to ten days. If nasal discharge persists longer, one can suspect a complicating infection of one of the sinuses. As recovery progresses, the nasal congestion and stuffiness decrease and the secretions become scanty and more purulent. Most treatment is directed toward the relief of symptoms. Bed rest is advisable in the early stages of an acute cold to protect others from exposure, increase general resistance and keep the body warm. Hot baths, consisting of hot water, hot air or steam, are frequently advocated for the treatment of colds. Their effect is to dilate the blood vessels of the skin and increase the blood flow through them. As a result nasal congestion and stuffiness are reduced. The relief from such baths, however, is only temporary, and if the body is chilled following a hot bath the cold may become more severe. Large quantities of liquids in the form of water, lemonade or orange juice are frequently recommended in the treatment of colds. Their value, however, is open to question. Advertised and recommended treatments are legion; most of these do little more than give some temporary relief of certain symptoms. The salicylates, such as aspirin, and similar drugs give some relief from aching and reduce fever. Nose drops and inhalers of various types cause shrinking of the membranes of the nose and so give temporary relief of stuffiness and nasal congestion. Unfortunately, the reaction of the nasal membranes to these drugs frequently results in more swelling than was present before they were used. Experiments also show that most preparations used in the nose stop the action of and in many instances actually destroy the cilia which play an important role in nature's defenses against infections.

Colds are of such variable severity and duration that individual experience is of little significance in judging the value of any preparation for either prevention or treatment. For this reason, the value of any medication for the treatment of colds can be determined only by carefully controlled experiments. Such studies were conducted over a period of approximately five years at the University of Minnesota. The subjects in the studies were all treated in the same manner and all thought they were receiving the same medications. Actually some received capsules or tablets of only starch or milk sugar. These subjects served as the control group. The importance of having this group was obvious when approximately 35% of the subjects in it reported that "the medication resulted in complete cure or marked improvement of their colds in 24 to 48 hours." Such results explain why it is so easy to become enthusiastic about any preparation for the treatment of colds if it is recommended by well-meaning friends or sufficiently promoted by skilful advertising. Of the preparations studied, the only ones found to be of any real value were derivatives of opium. In this connection, it is of interest to note that various writers on opium such as Thomas De Quincey in his *Confessions of an English Opium Eater* state that opium addicts never catch cold. The preparation found by these studies to be of greatest value was a mixture of codeine and papaverine. Quinine and aspirin seemed to be of a little benefit, but most of the preparations widely utilized for the treatment of colds were of no more value than the sugar tablets. The antihistamine drugs were promoted for the treatment of colds until controlled studies showed them to be of little or no value. Various preparations of the sulfonamides, penicillin and other antibiotics are widely utilized in the treatment of colds. Critical studies of these preparations and the most reliable authorities on their utilization, however, agree that there is no justification for their use in the general treatment of colds. On the contrary, there are definite objections to their use for this purpose. One is that a certain number of persons get reactions

of greater or less severity to the sulfonamides and even to penicillin. Another is that if these drugs are used for minor infections, such as colds, there may develop in the nose and throat strains of germs which are resistant to these drugs. When this occurs, they are valueless for the treatment of severe infections to which these germs may give rise. (H. S. DL.)

COLDEN, CADWALLADER (1688–1776), American physician, historian and colonial official, was born at Duns, Scotland, on Feb. 17, 1688. He graduated at the University of Edinburgh in 1705, devoting himself to scientific studies there and in London, and emigrated to Philadelphia in 1710. There he engaged in general mercantile business until after a visit to Great Britain in 1715 when he began the practice of medicine. He was induced to move to New York by Gov. Robert Hunter, who appointed him the first surveyor general of the colony and master in chancery. Becoming a member of the provincial council in 1721, he served for many years as its president; and from 1761 until his death was lieutenant governor. He was acting governor when in 1765 the stamped paper to be used under the Stamp act arrived in the port of New York; a mob burned him in effigy in his own coach in Bowling Green, and he was compelled to surrender the stamps to the city council, by whom they were locked up in the city hall until all atempts to enforce the new law were abandoned. Subsequently Colden secured the suspension of the provincial assembly by an act of parliament. He understood, however, the real temper of the patriot party and in 1775, when the outbreak of hostilities seemed inevitable, he strongly advised the ministry to act with caution and to concede some of the colonists' demands. When the war began he retired to his country seat near Flushing, N.Y., where he died on Sept. 28, 1776. Colden was widely known among scientists and men of letters in England and America. He was a lifelong student of botany, and was the first to introduce in America the classification system of Linnaeus, who gave the name *Coldenia* to a newly recognized genus. He wrote several medical works of importance in their day, the most noteworthy being *A Treatise on Wounds and Fevers* (1765); he also wrote an elaborate work on *The Principles of Action in Matter* (1751), which, with his *Introduction to the Study of Physics* (*c.* 1756), his *Enquiry into the Principles of Vital Motion* (1766), and his *Reflections* (*c.* 1770), mark him as the first of American materialists and one of the ablest material philosophers of his day. His *History of the Five Indian Nations* (1727, best ed. 1902) is one of the most valuable accounts that has been preserved of the relations with these powerful tribes and of the expansion of the English fur trade to the west.

Riley, *American Philosophy* (1907). Colden's *Letters and Papers* were published in the *Collections* of the New York Historical Society (1917–23).

COLD HARBOR, OLD and NEW, two localities in Hanover county, Virginia, U.S., 10 mi. N.E. of Richmond. They were the scenes of a battle between the army of the Potomac under Gen. G. B. McClellan, and the army of Northern Virginia under Gen. R. E. Lee, June 27, 1862 (sometimes called the battle of Gaines' Mill); also of a succession of battles from May 31 to June 12, 1864, between the Union forces under command of Gen. U. S. Grant and the Confederates under Gen. R. E. Lee, who held a strongly entrenched line at New Cold Harbor. The main union attack on June 3 was delivered by the 2nd (Hancock), 6th (Wright) and 18th (W. F. Smith) corps, and was brought to a standstill in eight minutes. An order from army headquarters to renew the attack was ignored by the officers and men at the front. In the constant fighting of May 31 to June 12 on this ground, Grant lost 14,000 men. (*See* AMERICAN CIVIL WAR; WILDERNESS.)

COLD STORAGE: *see* REFRIGERATION AND ITS APPLICATION.

COLDSTREAM, a small burgh, Berwickshire, Scotland. Pop. (est. 1951) 1,294. It is situated on the north bank of the Tweed, there spanned by John Smeaton's fine bridge of five arches, erected in 1763–1766, 13½ mi. southwest of Berwick by the Scottish Region railway. The station is at Cornhill over the border. Owing to its position on the border and also as the first ford of any consequence above Berwick, the town played a prominent part in Scottish history during many centuries. There Edward I crossed the stream in 1296 with his invading host, and the 5th earl of Montrose with the Covenanters in 1640. Of the Cistercian priory, founded about 1165 by Cospatric of Dunbar, and destroyed by the 1st earl of Hertford in 1545, which stood a little to the east of the present market place, no trace remains; but for nearly 400 years it was a centre of religious fervour. There the papal legate, in the reign of Henry VIII, published a bull against the printing of the Scriptures; but the site was occupied in the 19th century by an establishment, under Adam Thomson, for the production of cheap Bibles. There General Monk crossed the Tweed in 1659 with the regiment now famous as the Coldstream Guards. Like Gretna Green, Coldstream was long a resort of runaway couples, the old toll house at the bridge being the usual scene of the marriage ceremony. Marriage house, as it is called, still exists. At Birgham, 3 mi. west, a place of no small importance, in 1188 William the Lion conferred with the Bishop of Durham concerning the attempt of the English Church to impose its supremacy upon Scotland; there in 1289 was held the convention to consider the marriage of the Maid of Norway with Prince Edward of England; and there, too, in 1290 was signed the treaty of Birgham, which secured the independence of Scotland. Seven miles below Coldstream on the English side are the massive ruins of Norham castle, made famous by Scott's *Marmion,* and from the time of its building by Ranulf Flambard in 1121 a focus of border history during four centuries.

COLDWATER, a city near the southern boundary of Michigan, U.S., surrounded by beautiful lakes; the county seat of Branch county. It is on federal highways 27 and 112, and is served by the New York Central railway system. The population in 1950 was 8,594. It manufactures furnaces, marine engines, gray iron castings, brass, clothing, shoes, window-display fixtures, wooden sporting goods, sleds, coin-sorting machines and lawn furniture. The Michigan State Children's village is situated there.

Coldwater (called Lyons until 1833) was settled in 1829, incorporated as a village in 1837 and as a city in 1861.

COLE, SIR HENRY (1808–1882), English civil servant, was born at Bath on July 15, 1808. He was a leading member of the commission that organized the Great Exhibition of 1851, and then became secretary to the School of Design, which was transferred in 1853 into the Department of Science and Art. Under its auspices the South Kensington (now Victoria and Albert) museum, London, was founded in 1855 and Cole practically became its director, retiring in 1873. He originated the scheme for the Royal Albert hall, London. He was active in founding the national schools for cookery and music, the latter the germ of the Royal College of Music. He edited the works of Thomas Love Peacock. He died on April 18, 1882.

See A. S. and H. Cole (eds.), *Fifty Years of Public Work of Sir Henry Cole* (1884).

COLE, THOMAS (1801–1848), U.S. landscape painter, was born at Bolton-le-Moors, Eng., on Feb. 1, 1801. In 1819 the family emigrated to the U.S., settling first in Philadelphia, Pa., and then at Steubenville, O., where Cole learned the rudiments of his profession from a wandering portrait painter named Stein. He went about the country painting portraits, but with little financial success. Moving to New York (1825), he displayed some landscapes in the window of an eating house, where they attracted the attention of the painter Col. John Trumbull who sought him out, bought one of his canvases, and found him patrons. From this time Cole was prosperous. He is best remembered by a series of pictures consisting of four canvases representing "The Voyage of Life," and another series of five canvases representing "The Course of Empire," the latter now in the gallery of the New York Historical society. They were allegories, in the taste of the day, and became exceedingly popular, being reproduced in engravings with great success. The artist's genuine fame must rest on his landscapes. He had an influence on his

time and his fellows which was considerable, and with Durand he may be said to have founded the early school of American landscape painters. Cole spent the years 1829–32 and 1841–42 abroad, mainly in Italy, and at Florence lived with the sculptor Horatio Greenough. After 1827 he had a studio in the Catskills which furnished the subjects of some of his canvases, and he died at Catskill, N.Y., on Feb. 11, 1848. His pictures are in many public and private collections. His "Expulsion from Eden" is in the Metropolitan museum in New York city and is one of the most typical examples of his style.

COLE, TIMOTHY (1852–1931), U.S. wood engraver, was born in London in 1852, his family emigrating to the United States in 1858. He established himself in Chicago, Ill., where in the great fire of 1871 he lost everything he possessed. In 1875 he moved to New York city, finding work on the *Century* (then *Scribner's*) magazine. He immediately attracted attention by his unusual facility and his sympathetic interpretation of illustrations and pictures, and his publishers sent him abroad in 1883 to engrave a set of blocks after the old masters in the European galleries. These achieved for him a brilliant success. His reproductions of Italian, Dutch, Flemish and English pictures were published in book form with appreciative notes by the engraver himself. Though the advent of new mechanical processes had rendered wood engraving almost a lost art and left practically no demand for the work of such craftsmen, Cole was thus enabled to continue his work, and became one of the foremost contemporary masters of wood engraving. He received a medal of the first class at the Paris exhibition of 1900, and the only grand prize given for wood engraving at the Louisiana Purchase exposition at St. Louis, Mo., in 1904. He was an honorary member of the Society of Sculptors, Painters and Engravers, London, and a member of the American Academy of Arts and Letters. He was the author of *Notes to Old Italian Masters* and other critical essays. He died May 17, 1931.

COLE, VICAT (1833–1893), English painter, born at Portsmouth on April 17, 1833, was the son of the landscape painter George Cole, and in his practice followed his father's lead with marked success. He became an academician in 1880, and died in London on April 6, 1893. Most of his subjects were found in the counties of Surrey and Sussex, and along the banks of the Thames.

One of the largest pictures, "The Pool of London," was bought by the Chantrey Fund trustees in 1888, and is in the Tate gallery, London.

See Robert Chignell, *The Life and Paintings of Vicat Cole, R.A.* (1899).
